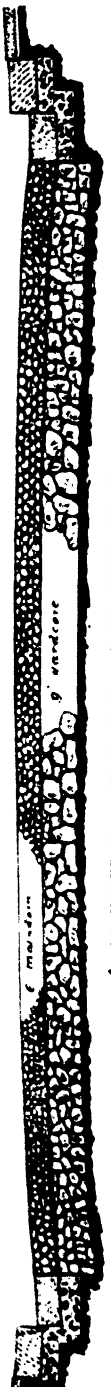
When the metal is not rolled divide 36 by the thickness of the proposed coating in inches, the quotient is the number of superficial yards that can be covered. When the metal is rolled divide 27 by the thickness in inches to give the required quotient.

A commonly adopted rule for ascertaining the camber of a macadam road is as follows:

Width of road, say, 30 ft.
At 4 ft. from centre (on each side), fall ½ in.
„ 9 „ „ „ „ „ „ 2 in.
„ 15 „ „ „ (its extreme edge), 6 in.



1. TRANSVERSE SECTION OF MACADAM CARRIAGEWAY

This class of road is repaired by the old worn surface being picked up by manual labour, or by means of a scarifier, the new metal being put on and then steam-rolled with a small addition of matrix.

Tar. While it is only within comparatively recent years that tar macadam has been applied to road-making purposes, it has been used in Nottingham for upwards of 40 years, where the first piece of tar macadam was laid in this country. A few years ago, some Belgian engineers were sent over by his Majesty the King of the Belgians to make inquiries regarding the construction of tar macadam roads. The result of their visit was the making of a tar macadam road from Ostend to Blankenberghe, a distance of about 10 miles.

There is nothing new in the principle of mixing tar with road metal; but a material manufactured from the best hand-picked selected iron slag, and mixed by machinery specially designed, has been introduced to comply with the largely expressed desire for a tar macadam suitable for roadways, and is specially intended to meet the greatly increasing motor and other similar traffic which is now proving so damaging to the ordinary macadam road, principally due to the suction set up by the rubber tyres, which result in the disintegration of the finer material.

Cost of Tar Macadam. With roads made of tar macadam, the initial cost is not very much in excess of that for ordinary macadam, while the life is considerably greater, thus largely reducing—by 40 to 60 per cent.—the cost of repairs, and the expenses of scavenging.

The material is non-slipping, and has been laid on slopes and cambers of as much as 1 in 30 without any more effect than on an ordinary macadam road.

Preparation of Roadway. The surface of the roadway or other area proposed to be paved should (in the case of an existing road or old foundation) be scarified by a steam scarifier, or picked over by hand labour and levelled, to leave a camber, or fall, of the cross section of ½ in. to ¾ in. to 1 ft., care being taken to excavate all soft and weak places, which should be taken out at least 1 ft. in depth, and filled in with good dry hard core. The whole surface should then be moderately steam-rolled to ensure thorough consolidation (which is a very essential point), but the rolling should be discontinued before the surface becomes "smooth," as a "key" is necessary, and an air circulation is required in the foundation.

Laying the Tar Macadam. The tar slag-macadam is then laid on the foundation prepared as above in two coats of varying thicknesses, according to the traffic or purposes for which it is required, each coat being well rolled with steam-roller, weighing not more than 6 tons, and the surface on completion being dusted over with fine chippings, and finally well rolled until it is quite hard. The material of the *bottom* coat should be spread with shovels in the same way as ordinary macadam, and should be allowed to lie open before being rolled, for at least 24 hours, to allow it to become partially set and *tough*, which ensures the levels remaining true; and the *top* coat laid with rakes (kept heated) to enable a level and true surface to be obtained. This coat should also remain open a few hours before rolling, and, where possible, the rolling of the material should not be done during rain or until it has had sufficient time to dry.

The thickness at which the material should be laid may be taken generally as shown below.

Roadways with local or through traffic. Work to be laid in two coats, totalling 4½ in. in thickness.

Bottom coat, 3½ in. thick of 2-in. gauge material.

Top coat, 1 in. thick of ¾-in. gauge material.

Roadways with light traffic. Work to be laid in two coats, totalling 3½ in. in thickness.

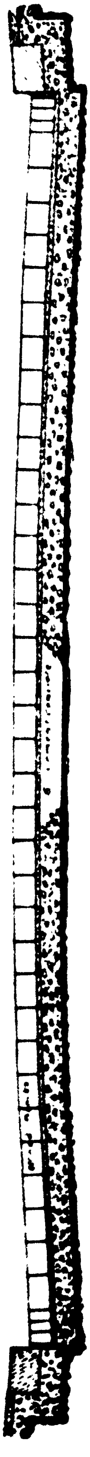
Bottom coat, 2¾ in. thick of 2-in. gauge material.

Top coat, ¾ in. thick of ⅝-in. gauge material.

The life of this description of paving may be taken as seven and five years respectively.

Wood Paving. The first wood-paved roadway laid in London was in front of Old Bailey in 1839. Since this date wood has made giant strides as a street paving. "It is admitted by all that it is of little use to lay any pavement without a good and substantial foundation, and none of the substances used requires this more than wood. Such being the case, a substantial concrete foundation is first laid, and it should cost the same, whether granite, wood, or other material be placed upon it; consequently, the only thing to be considered is the cost of the wearing surface, the lasting qualities of same, and its desirability as a pavement when completed." A section of a wood-paved carriage-way is shown in 2.

Woods for Paving. A wood pavement as now laid consists of a good hard foundation of Portland cement concrete laid 6 in. thick and floated over to an even surface, conforming with the contour line of the proposed finished road. When sufficiently set, rectangular blocks of Jarrah, Karri, or others of the eucalyptus or blue gum types, 9 by 6 by 5 in., on the face, cut die square, with the fibre vertical, are laid with close joints upon the finished surface of the concrete. To allow for the expansion of the wood transversely across the street, a 1½-in. expansion joint of sand is provided next to the kerb.



2. TRANSVERSE SECTION OF WOOD-PAVED CARRIAGEWAY

Filling the Interstices. The interstices between the blocks are sometimes grouted with liquid Portland cement and fine sand, a bituminous mixture of tar and pitch, or tar alone. The mixture is poured over the surface and "squeegeed," or brushed until it disappears between the wood blocks. The surface is then sprinkled with coarse sand or fine grit, and the traffic allowed to squeeze it, thus preserving its life and rendering the wood less slippery.

Creosoting the Blocks. If soft woods are used, the blocks should be creosoted by at least 10 lb. of creosoted oil being driven into every cubic foot of wood, so that each block may be thoroughly penetrated. The life of the blocks is not materially increased by the creosoting, but they are rendered less absorbent.

The life of this pavement depends upon the amount of traffic, quality of the material used, the locality (whether open or confined), and the width of the street, but the average estimated wear of Jarrah or Karri wood blocks may be taken at the rate of ¾ in. per annum.

Karri wood is hard, heavy, and tough, and it is recognised as one of the most durable woods for street paving. It is cut from a tree whose average height is 200 ft. by 4 ft. in diameter at 3 ft. to 4 ft. from the ground, and has its first branches at a height of 120 ft. to 150 ft. The concrete foundation is similar to that already described under Granite Setts.

Future of Wood Paving. Like every other system of paving, wood has its advocates and opponents, its advantages and its disadvantages. One thing, however, is certain—it has come to stay, for whatever its opponents may say against it, it possesses the advantages the general public demands, and the public, who pays the piper, has a right to call the tune.

Soft woods have been used mostly in London on account of their being less noisy under traffic than hard woods, but their chief objection is that they wear more quickly than hard woods.

The comparative expansion of creosoted against plain soft wood blocks, after immersion in water for 48 hours has been found to be as follows:

On length of block	creosoted		·090	plain	·6
,, width	,,	,,	·57	,,	·83
,, depth	,,	,,	·15	,,	·31

These represent in a thirty feet carriage-way, 2½ inch for plain blocks and practically ⅜ inch for creosoted blocks, if under the same conditions.

PRELIMINARY EXERCISES FOR SHADING WITH LEAD PENCIL.

Continued from page 2010

LIGHT AND SHADE

Drawing with Lead Pencil. Value of Line. Treatment of Surfaces. Suggestion of Light and Shade with Pencil, Crayon, Charcoal, etc.

By WILLIAM R. COPE

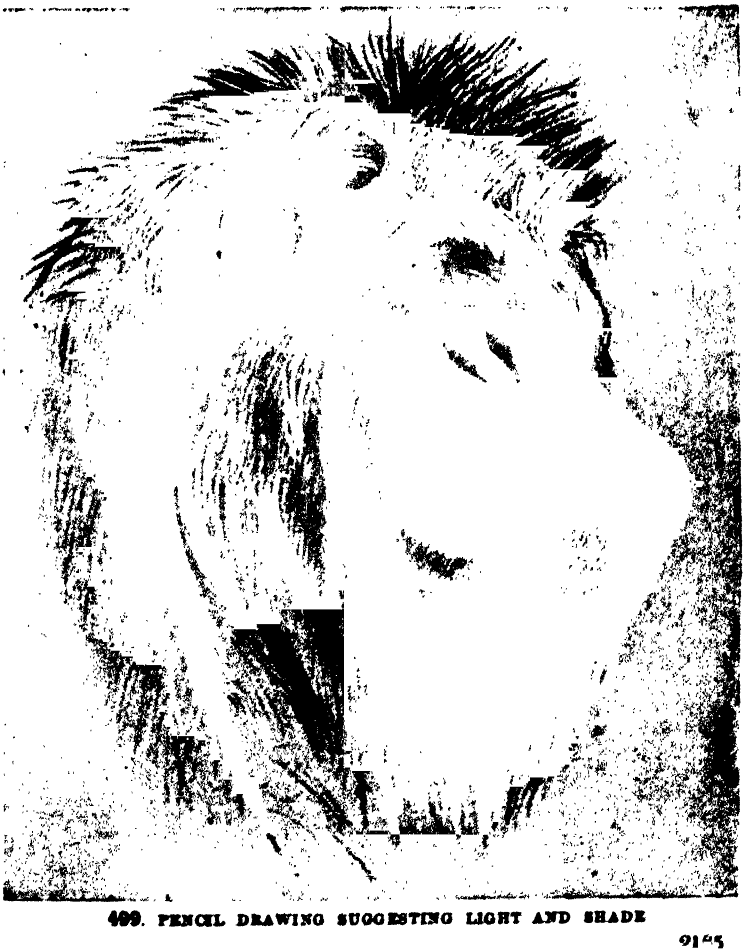
Lead Pencil. It seems a great pity that ordinary lead pencil is not used more often than it is as a medium for artistically representing light and shade, to say nothing of expression, action, etc.

The pencil is clean, easy to handle, gives excellent results with a comparatively small amount of labour, and permits of a very high degree of "finish" in the drawing done with it. The "shine" and the likelihood of lines being smeared and rendered greasy in appearance when rubbed with the indiarubber, are perhaps its only disadvantages. It is the handiest and most workable material at the artist's disposal, and the most complicated and subtle effects of light and shade may be accurately expressed with it. It is possible with this medium to treat delicate gradation of tone as successfully as strong contrasts of deep and light tones, and to represent dainty modelling as easily as rugged forms.

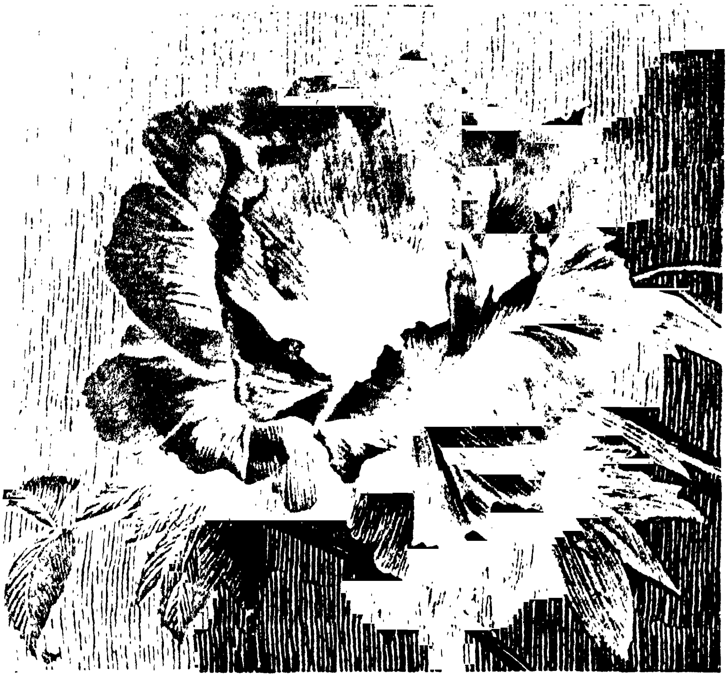
The work, too, need not necessarily be laboured and weak, but breadth and largeness of massing of different tone areas may be secured with such an implement, because, by making broad strokes of the pencil that quality which water-colour washes give may be expressed with it. There is also the possibility of very minute detail with the point. Besides the ordinary HB, B, or BB pencils there is no objection to the use of a carpenter's pencil in order to obtain certain broad effects. Almost any paper which is not too rough is suitable for the drawing.

Method of Shading with Lead Pencil. By intelligently placed strokes of the pencil, the *direction* of surface, whether curved, vertical, horizontal, or receding, as well as the light and shade of different tone values, may be represented, which will conduce to careful study of form; for, if the latter be not observed, the direction of stroke cannot be given properly.

Figures **485**, **487** and **489** show how the groundwork should be done for three different keys of tone, while **486**, **488**, and **490** indicate how each may be more highly finished to obtain a closer and more even tone. The length of each stroke should be that which can be comfortably and evenly executed with each movement of the



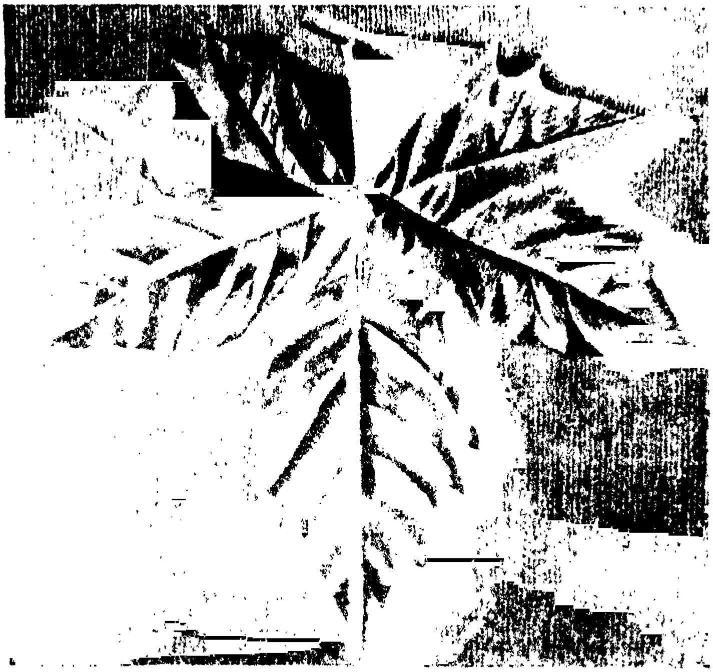
499. PENCIL DRAWING SUGGESTING LIGHT AND SHADE



500. STUDY IN LEAD PENCIL OF A PEONY

hand or fingers. When an even tone is required, care should be taken not to let the ends of each stroke overlap the one above or below it, or the tone will have an undulating appearance.

Direction of Stroke. The direction of the stroke should be suited to the direction of the surface as much as possible. Thus, **491** shows vertical lines for a vertical surface. The oblique cross-lines are intended to represent a change of tone sometimes required on such a vertical surface, although it might well be represented by thicker lines perhaps closer together, *all vertical*, with no cross-hatching, in the same manner as the lines for the curved surface of the cylinder in **498**. A horizontal surface should be represented by horizontal lines, as in **492** and several succeeding examples. A [illegible]



[illegible] STUDY O[illegible] A [illegible]

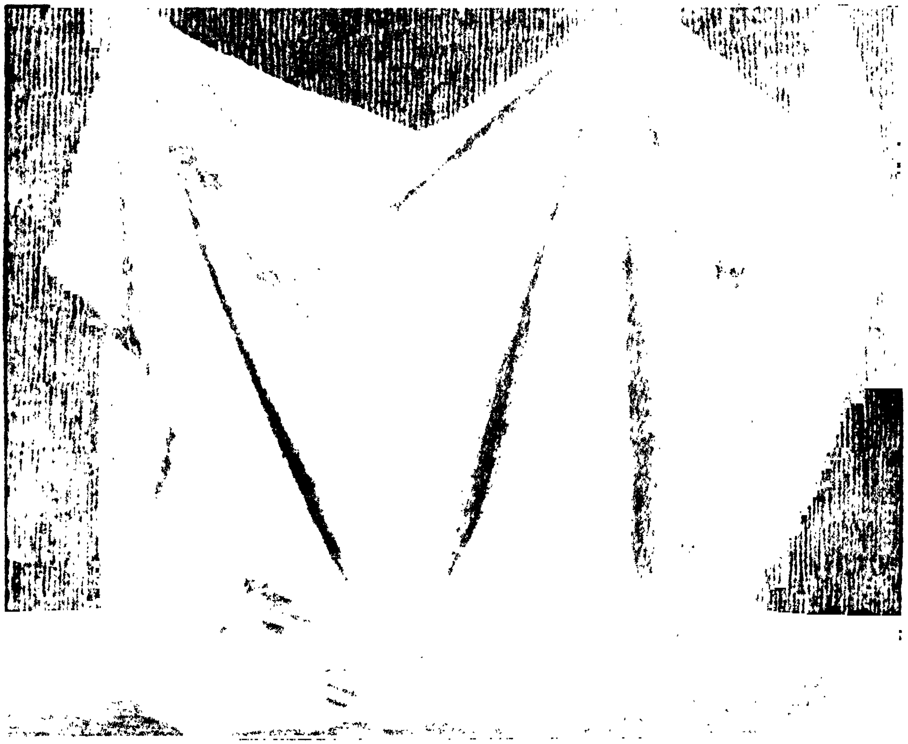
have its groundwork as in **493**, which is carried a stage further in **494**, but is rather coarse. A more delicate rendering is given in **495**. In both **494** and **495** some of the lines cross one another nearly at right angles; this is not always pleasing, and a more artistic appearance is shown in the sloping surfaces of the hexagonal prism in **498**.

Straight and Curved Lines. The student must simplify his lines as much as possible when he wishes to render a tone quickly and in as direct a way as possible, as in **496**, where there is no cross-hatching whatever, and yet there is a good appearance of roundness and relief. Fig. **497** is more highly finished, but some artists would prefer the drawing in **496** to that in **497**. It should be noticed that curved lines are used in **497** on the curved surface; these are drawn in the direction of the curvature of the surface. In 498 we have representations of horizontal, vertical, oblique, and curved surfaces. The student should carefully note the direction, varying thickness, and closeness of the lines used. In the sphere there are no straight lines at all, but curved ones crossing one another in such a way that there is no ugly appearance of reticulation as in 494, and the lines are drawn in a free and light manner

It is no good to rub the pencil about anyhow on the paper; but before each stroke is made there should be a definite idea in the student's mind of what he wishes to represent. This accuracy can only be obtained by very careful and searching observation of the object.

Shading Suggestive of Form. Fig. 499 is an example of pencil shading to suggest form without absolute accuracy of the relative values of the individual tones, whereas, in 498, the latter are supposed to be quite accurate in relative value. The method used in 499 is very suitable for rapid sketching. Observe, in this example, the direction in which the lines are drawn; they follow, more or less, the curvature of the different muscles.

Study of Maple Leaf. The study of a cast of a maple leaf in 501 has the pencil work done with little or no cross-hatching, and the lines are rather wider apart than those used in 498 and 499. Thus, the work is more direct, and executed with less labour, although the tone values are practically true in relation to one another. Notice the vertical lines for the vertical background, and the varying directions of the lines for the numerous undulations of the surface of the leaf. It would have been quite possible to use fewer lines still, and yet obtain truth of tone. The student must use his discretion in this respect. He should study good examples by well-known artists, see how they have used the lines with intelligence, and have made each one do its proper duty; then he will be trained to use them in the correct way.



502. HIGHLY-FINISHED SHADING WITH LEAD PENCIL

Study of Drapery. The study shown in 502 is carried to a very high degree of finish, and was executed on smoother paper than that used in 485—501, and 503. At first a fairly even tone was put over each mass with a broad, soft pencil, but each even tone was of a varying degree of value. Then line work of a finer nature was worked on the top, the artist all the time carefully endeavouring to render accurately the modelling of the many folds. As will be seen in the reproduction, the material was moderately dark in colour, and somewhat soft, with a texture like cloth. The student must always endeavour to indicate the material to be represented, so that one knows whether it is cloth, silk, satin, flannel, leather, or other material. This will give

503. SHADING IN PURE LINE WITH LEAD PENCIL

him plenty of exercise in choice of line most suitable for the representation of the material being studied. Lines of totally different *consistency and character* should be used to express *rough* or *smooth surfaces*; for example, it is obvious that one must use entirely different *qualities of line* to represent the smoothness of an egg-shell, the roughness of texture of the scaly surface of a pine-cone, the soft feathers of a bird, the hair of animals, delicate human features, flowers, and thin drapery.

Study of Outdoor Life. The drawing of an old house shown in **503** exemplifies how the lead pencil may be used for outdoor studies. Again, notice the direction of the lines and the different kinds used, and that in the very dark portions the lines are so very close together that they do not show individually, but appear like a dark wash of colour. The original drawing was done on Whatman's "not" paper.

Flower Study. The flower study in **500** shows the kind of line which may be obtained on ordinary cartridge paper with a moderately smooth surface.

Shading with Other Mediums. What has been said in this lesson about lead-pencil work may be applied, with little variation, to drawings executed in carbon pencil, Conté crayon, or charcoal. With the last medium it is sometimes advisable to rub down the groundwork carefully and judiciously with the finger or thumb, or a paper stump, and then use line work upon that.

Charcoal, being halfway between the flexible brush and the firm, hard point of the pencil or pen, is a great favourite with most artists. Its softness and the ease with which it may be altered make it a very good medium for rapid studies in line or tone, or a mixture of both, in order to seize the effect of light and shade. Charcoal is capable of both delicacy and force, and bears working up to any extent. A gentle rubbing of the finger gives half tones when required, and helps to give greater solidity and finish to the drawing. This appearance of solidity may be further strengthened by letting the lines of shading, say for the deep shadows of drapery, run into solid blacks in the deep interstices of the folds. The latter principle is applicable to drawings made with either charcoal, crayon, chalk, pencil, pen, or brush.

In drawings done with carbon, pencil, and Conté crayon, each stroke, even the thinnest, is apt to become too black, unless the medium is used with caution and with the lightest possible touch. Also the work cannot very easily be corrected, owing to the difficulty of rubbing out the lines. Nevertheless, in the hands of those artists who know exactly what they wish to record, the use of such mediums will produce excellent results.

THE ARTICLES

The Spanish definite articles are : *el*, the, feminine *la*, neuter *lo*.

The indefinite articles are : singular, masculine *un*, a, an ; feminine *una* ; plural, masculine *unos* ; feminine *unas*.

The definite articles are as follows :

MASCULINE.

Singular.	*Plural.*
El, the	*Los*, the
Del, of the	*De los*, of the
Al, to the	*A los*, to the

FEMININE.

La, the	*Las*, the
De la, of the	*De las*, of the
A la, to the	*A las*, to the

NEUTER.

Lo, the	There is no plural
De lo, of the	
A lo, to the	

Del and *al* were formerly written *de el, á el* ; the contracted form has been adopted for the sake of euphony.

The masculine article *el* is used with nouns of the feminine gender beginning with *a* or *ha*, when the stress is on the first syllable, as : *el agua*, the water ; *el alma*, the soul ; *el águila*, the eagle ; *el hacha*, the hatchet ; *el hada*, the fairy. In these cases the masculine article is adopted only in the singular for the sake of euphony, and the feminine article must be used in the plural : *las aguas*, *las almas*, *las águilas*, *las hachas*, *las hadas*. Other nouns beginning with *a*, as : *alegria*, joy ; *aguja*, needle ; *alhaja*, jewel, in which the stress is not on the first syllable, take the feminine article.

The masculine article *el* is sometimes used before the infinitive of a verb expressing a substantive idea, as : *el leer me gusta mucha*, I am fond of reading, or, reading pleases me very much : *el cantar bien es muy dificil*, it is very difficult to sing well ; or, good singing is very difficult.

The article is sometimes omitted after a verb followed by the words *casa*, house ; *palacio*, palace ; *paseo*, walk ; *misa*, mass, and others, as : *salgo de casa*, I am going out of the house : *voy á palacio*, I am going to the palace. But if a particular house or palace is specified the article is retained, thus : *salgo de la casa de mi padre*, I am going out of my father's house : *voy al palacio del rey*, I am going to the king's palace.

The plural of the indefinite article *unos*, *unas*, may be translated as some, or sometimes may be omitted, as : *He visto unos niños bailando*, I saw some children dancing, or, I saw children dancing.

The abuse of the indefinite article is denounced by the Spanish Academy as a Gallicism. Thus : *Puede muy bien cualquiera llegar a ser un gran hombre, sin estar dotado de un talento ni de un ingenio superior, con tal que tengo valor, un juicio sano, y una cabeza bien organizada.* (Anyone may come to be a great man without possessing a superior genius or talent, so long as he has courage, a sound judgment, and a steady brain.) In Spanish all the indefinite articles in this passage are superfluous.

Vocabulary	**Vocabulario**
Metals	Metáles
Gold	El oro
Silver	La plata

Echar

21. The anchors of the ships.
navíos.

Note. In translating transpose the words as numbered.

PROSE EXTRACT II.

From "Lazarillo de Tormes," by Diego Hurtado de Mendoza.

How Lazaro took service with a priest, and of the things he endured with him.

Como Lázaro se asentó con un clérigo, y de las cosas que con él pasó.

The next day not thinking myself safe there I went to a place called Maqueda, where, for my sins, I fell in with a priest, of whom I asked alms. He asked me whether I knew how to serve mass. I said "Yes," which was true enough, for, though he ill-treated me, the blind sinner taught me many good things, and that was one of them. In the end the priest received me into his service.

Otro dia, no pareciéndome estar alli seguro, fuime á un lugar que llaman Maqueda, adonde me toparon mis pecados con un clérigo, que llegando á pedir limosna, me preguntó si sabia ayudar á misa. Yo dije que si como era verdad, que aunque maltratado mil cosas buenas me mostró el pecador del ciego, y unas de ellas fué esta. Finalmente, el clerigo me recibió por suyo.

I escaped the thunder and caught the lightning; for the blind man, though avarice itself, as I have related, was an Alexander the Great compared to this man. I will only say that all the stinginess on earth was incarnate in him. I do not know whether it was his own nature or if he had assumed it with his clerical habit. He had a large old chest secured with a key which he carried about fastened to the strap of his scapulary, and when the charity bread came from the church he would throw it in at once with his own hands, and lock the chest again. There was not a single eatable about the house, such as are usually seen in other houses: some bacon hanging in the chimney, a plate of cheese upon some shelf or in the cupboard, a (some) small basket with a few pieces of bread left over from the table; and it seemed to me that though they were no profit to me the sight of them would console me. There was nothing but a string of onions, under lock and key in a room at the top of the house.

Escapé del trueno y di en el relámpago; porque era el ciego para con este un Alejandro Magno, con ser la misma avaricia como he contado. No digo mas, sino que todo la laceria del mundo estaba encerrada en este, no sé si de su cosecha era, ó lo habia anejado con el habito de clerecia. Él tenia un arcaz viejo y cerrado con su llave, la cual traia atada con un agujeta del paletoque; y en viniendo el bodigo de la iglesia, por su mano era luego alli lanzado, y tornada á cerrar el arca. En toda la casa no habia ninguna cosa de comer, como suele estar en otras; algun tocino colgado al humero, algun queso puesto en alguna tabla, ó en el armario, algun canastillo con algunos pedazos de pan que de la mesa sobran, que me paresce a mi que aunque de ello no me aprovechára, con la vista dello me consolára. Solamente habia una horca de cebollas, y tras llave, en una cámara en lo alto de la casa.

My allowance of these was one every four days, and when I asked for the key to go and fetch it, if anyone were present he would put hand to pouch with great gravity, and untie the key and give it to me, saying, "Take it and return it directly, and do no more than feast your eyes," as though it unlocked all the preserves of Valencia, whereas there was not a cursed thing in the room (as I have said) except the string of onions hanging from a nail, and of these he kept so strict a count that if, for my sins, I had exceeded my allowance, it would have cost me dear.

Destas tenia yo de racion una para cada cuatro dias, y cuando le pedia la llave para ir por ella, si alguno estaba presente, echaba mano al balsopeto, y con grán continencia la desataba y me la daba diciendo, "toma y vuélvela luego y no hagais sino golosmear; como si debajo de ella estuvieran todas las conservas de Valencia, con no haber en la dicha cámara (como dije) maldita otra cosa que lás cebollas colgadas de un clavo, las cuales él tenia tambien por cuenta, que si por malos de mis pecados me desmandára á mas de mi tasa, me costara caro.

At last I was nearly dead with hunger. But though he had small charity towards me he showed more to himself. Five half maravedis worth of meat was his allowance for dinner and supper. It is true that he gave me a share of the broth, but clear as my eye of meat, and with only a little bread—I would to God he had gone halves with me.

Finalmente, yo me finaba de hambre. Pues ya que conmigo tenia poca caridad, consigo usaba mas. Cinco blancas de carne era su ordinario para comer y cenar. Verdad es que partia conmigo del caldo, que de la carne tan blanco el ojo, sino un poco de pan, y pluguiera á Dios que me demediara.

It is the custom of that country to eat sheep's heads on Saturdays. He would send me for one costing three maravedis. Then he would cook it, and eat the eyes, tongue, brain, and meat off the skull and jaws, and give me all the gnawed bones on the dish, saying, "There, take it, eat. Triumph, you have everything on earth; you fare better than the Pope." "God send you the same," said I to myself.

Los sabados cómense en esta tierra cabezas de carnero, y enviábame por una que costaba tres maravedis; aquella la cocia y comia los ojos, y la lengua, y el cogote y sesos, y la carne que en las quijadas tenia, y dábame todos los huesos roedos, y dábamelos en el plato diciendo, "toma, come, triunfa, que para ti es el mundo; mejor vida tienes que el papa." "Tal te la dé Dios," decia yo paso entre me.

Diego Hurtado de Mendoza (1503-1575) was one of the most celebrated men of his age; a scholar, soldier, poet, statesman, and historian.	Diego Hurtado de Mendoza (1503-1575) fué uno de los hombres mas célebre de su tiempo, un literato, soldado, poeta, hombre político, é historiador.
"Lazarillo de Tormes," the autobiography of a beggar boy born on the banks of the Tormes, has been translated into nearly every European language. Short as it is, this book founded the school of the picaresque novel which Le Sage has made world renowned in "Gil Blas."	"Lazarillo de Tormes," la autobiografia de un muchacho mendigo, nacido en las orillas del Tormes ha sido traducido en casi todos los idiomas Europeos. Apesar de ser corto este libro ha fundado la escuela de la novela picaresca que Lesage en su Gil Blas ha hecho célebre en el mundo entero.

KEY TO EXERCISE I.

1. Las estrellas, los cometas, y la luna brillan en el firmamento.

2. Nada mas hermoso que el resplendor de la luna.

3. Pocos han visto la salida del sol.

4. La primavera es el tiempo mas agradable del año, el verano es demasiado caluroso. Los colores del otoño son pictorescos. El invierno no agrada á todos.

5. Un muchacho debe pasar por la niñez y la adolescencia antes de ser hombre.

6. La vejez es la precursora de la muerte.

7. Es una dicha que el porvenir nos sea desconocido.

8. El hombre no es mayor de edad hasta los veinte y un años.

9. La miseria es cruel.

10. El gasto de la educacion es grande.

ITALIAN

Continued from page 2048

By Francesco de Feo

NOUN SUBSTANTIVE

With the exception of a few names which end with a consonant (*gas*, *lapis*, etc.) all Italian nouns end with a vowel.

There are two genders in Italian—*masculine* and *feminine*.

The gender of the nouns may be known by their *signification* or by their *termination*.

1. By the signification:

(*a*) The names of metals, lakes, mountains (except *le Alpi*), months, and days of the week (except *la domenica*, Sunday) are masculine.

(*b*) The names of trees—except *la vite* (*veèteh*), the vine; *la querce* (*koo-èhrcheh*), the oak; *l'edera* (*èh-dehrah*), the ivy, are masculine.

Some names of trees have a corresponding feminine to indicate the fruit, as: *il noce* (*nò-cheh*), the walnut-tree; *la noce*, the walnut; *il pero* (*pèhro*), the pear-tree; *la pera*, the pear. Some names signify the fruit as well as the tree: *il limone* (*leemò-neh*), the lemon and the lemon-tree; *il fico* (*feèco*), the fig and the fig-tree.

Some fruits have a name quite different from that of the tree, as: *vite*, vine; *uva* (*oòvah*), grape; *palma*, palm-tree; *il dattero* (*dàhttehro*), the date.

2. By the termination:

(*a*) All nouns ending in *o* are masculine, except *mano* (*màhno*), hand, and *eco*(*èhco*), echo, in the singular.

(*b*) Nouns ending in *a*, *tà*, and *ù* (except *il Perù*) are feminine. Exceptions: *il patriarca*, *il monarca*, *il duca*, etc., and many names in *ma* and *ta*, of Greek origin, as: *il poeta*, *il clima*, *il poema*, *il pianeta*, etc.

(*c*) All nouns ending in *tore* are masculine, as: *il dottore* (*dottòreh*), doctor; *il genitore* (*dgeh-nee-tòreh*), father.

NOTE. *Calore* (*cah-lò-reh*) heat; *colore* (*colòreh*), colour; *dolore* (*dolòreh*), pain; *valore* (*vahlòreh*), value; *fiore* (*fee-ò-reh*), flower, which are feminine in French, are all masculine in Italian.

(*d*) All nouns ending in *ùdine*, *zìòne*, and many in *iòne* are feminine, as: *azione* (*ah-tsee-òneh*), action; *esposizione* (*ehsposee-tsee-òneh*) exhibition; *attitudine* (*ahttee-toò-deeneh*), attitude; *incudine* (*een-koò-deeneh*), anvil; *passione* (*pahssee-òneh*), passion; *confusione* (*confoo-see-òneh*), confusion.

(*e*) Nouns ending in *i*, which, however, are very few in Italian, are feminine, as: *la crisi* (*creè-see*), crisis; *la metròpoli* (*mehtròpolee*), the metropolis. Masculine are: *il brindisi*, *il Tamigi*, and some compound nouns ending also in *i*, as: *il portafogli* (*portah-fòlee-ee*), the pocket-book; *il portasigari* (*portah-seègah-ree*), the cigar-case.

Formation of Feminine Nouns.

1. (*a*) Proper names of persons ending in *o*, *e*, *i*; (*b*) common nouns, names of persons ending in *o*, and in *sore*; (*c*) and many in *e* form their feminine in *a*, as: *Alessandro*, *Alessandra*; *Claudio*, *Claudia*; *Giuseppe*, *Giuseppa*; *Luigi*, *Luigia*; *ragazzo*, *ragazza*, girl; *scolaro*, *scolara*; *uccisore*, *uccisora*; *padrone*, master, *padrona*, mistress, etc.

NOTE. The form *ditrice* for the feminine of some nouns in *sore*, as *difenditrice*, *ucciditrice*, etc., is now out of use.

2. Nouns in *tore* form their feminine in *trice*, as: *autore* (*ah-ootòreh*) author, *autrice* (*ah-ootreècheh*); *imperatore*, emperor, *imperatrice*; *pittore*, painter, *pittrice*, etc. Some nouns in *tore* have also a form in *tora*, as: *lavoratore* (*lah-vorahtòreh*), workman; feminine, *lavoratrice* and *lavoratora*. *Dottore* is used both for the masculine and the feminine.

Note. *Dottore* has also a form *dottoressa*, which is used in speaking of a woman who affects to be learned.

3. Some names in *a*, *e*, *o*, form their feminine in *èssa*, as: *poeta*, *poetessa*; *principe* (*preèn-chee-peh*), *principessa*; *barone* (*bahròneh*), *baronessa*; *filòsofo* (*feelòsofo*), *filosofessa*. Note here that *guàrdia* (*guàhr-dee-ah*), guard; *guida* (*gueèdah*), guide; *sentinella* (*sehnteenèhllah*), sentinel; *spia* (*speè-ah*), spy, although generally referring to men, are always feminine. The same may be said of *vittima* (*veèttee-mah*), victim.

4. All nouns ending in *ista*, and many ending in *e* (especially *ente*) are of both genders, as: *il pianista*, *la pianista*; *il violinista*, *la violinista*; *il parente* (*pahrèhnteh*), relation, *la parente*; *il conoscente* (*conoshèhn-teh*), acquaintance, *la conoscente*, etc.

Note. *Il fine* (*feè-neh*) the aim, *la fine*, the end.

5. Of the names of animals, those ending in *e* form the feminine in *essa*: *leone* (*leh-òneh*) lion, *leonessa*; those ending in *o* form the feminine in *a*: as *gatto* (*gàhtto*) cat, *gatta*.

But many names of animals have one form masculine or feminine for both genders, and must be distinguished, as in English, by the words *maschio* (*màhs-keeo*), male; *fèmmina*, female, as: *la mosca*, the fly; *la tigre* (*teègreh*), the tiger

6. Some names of persons and animals are quite irregular, and have, as is often the case in English, two different forms for the two genders. The most important are:

maschio (*màhs-keeo*), male
fèmmina (*fèhmmeenah*), female

uomo (*oo-òmo*), man
donna (*donnah*), woman
padre (*pàhdreh*), father
madre (*màhdreh*), mother
fratèllo (*frahtèhllo*), brother
sorella (*sorellah*), sister
marito (*mahreèto*), husband
mòglie (*mòlee-eh*), wife
gènero (*dgèh-nehro*), son-in-law

nuora (*noo-òrah*), daughter-in-law
patrigno (*pahtreè-nee-o*), stepfather
matrigna (*mahtreè-nee-ah*), stepmother

re (*reh*), king	*regina* (*rehdgeè-nah*), queen
eroe (*ehrò-eh*), hero	*eroina* (*ehro-eenah*), heroine
dio (*deè-o*), god	*dea* (*dèh-ah*), goddess

gallo (*gàhllo*), cock	*gallina* (*gahlleè-nah*), hen
pollo, chicken	*pollastra* (*pollàhstrah*), pullet
cane (*càhneh*), dog	*cagna* (*càh-nee-ah*), bitch
montóne, ram	*pècora* (*pèhcorah*), ewe
porco, pig	*tròia* (*trò-ee-ah*), sow (besides the regular *pòrca*)

bue or *bove*, *toro*, ox; *vacca* (*vàhccah*), cow

Exercise VII.

On the Gender of Nouns.

Il re e la regina sono a Windsor. L'imperatore e l'imperatrice della Russia andranno (will go) in Frància il mese d'agosto. La moglie della guàrdia è una donna lavoratora. Gli alpinisti e le guide si sono perduti (have lost themselves) nelle Alpi. Il bue, la vacca, la capra, la gallina sono animali utili (useful) all' uomo. La leonessa e la tigre sono più feroci del leone e della tigre maschio. La sorella di Luigi ha due fanciulli (two children), un maschio e una femmina. L'uva e il dattero sono i frutti della vite e della palma. Il fratèllo e la nipote della baronessa hanno intenzione di andare a Parigi. Una moltitudine di ragazzi e ragazze (boys and girls) sono in campagna (in the country) con la maestra e con la padrona di casa. Il gènero del dottore è un artista e la sorella è una pianista. La figlia del mèdico è dottore in lèttere e anche poetessa e pittrice, essa è autrice d'un poema e d'un quadro, che (which) è all'esposizione di Berlino.

Indicative Mood of the Verb

Avere (To Have).

Present.

Io ho, I have	*noi abbiamo*, we have
tu hai, thou hast	*voi avete*, you have
egli ha, he has	*essi hanno*, they have

Past Indefinite.

Io ho avuto, I have had
tu hai avuto, thou hast had
egli ha avuto, he has had
noi abbiamo avuto, we have had
voi avete avuto, you have had
essi hanno avuto, they have had

Imperfect.

Io avevo (*ahvèvoh*), I had	*noi avevamo*, we had
tu avevi, thou hadst	*voi avevate*, you had
egli aveva, he had	*essi avèvano*, they had

Pluperfect.

Io avevo avuto, I had had
tu avevi avuto, thou hadst had
egli aveva avuto, he had had
noi avevamo avuto, we had had
voi avevate avuto, you had had
essi avèvano avuto, they had had

Past Definite.

Io ebbi (*èh-bbee*), I had	*noi avemmo* (*ahvèhmmo*), we had
tu avesti, thou hadst	*voi aveste*, you had
egli ebbe, he had	*essi ebbero*, they had

Second Pluperfect.

Io ebbi avuto, I had had
tu avesti avuto, thou hadst had
egli ebbe avuto, he had had
noi avemmo avuto, we had had
voi aveste avuto, you had had
essi ebbero avuto, they had had

Future.

Io avrò (*ahvrò*), I shall have
tu avrai, thou wilt have
egli avrà, he will have
noi avremo, we shall have
voi avrete, you will have
essi avranno, they will have

Second Future.

Io avrò avuto, I shall have had
tu avrai avuto, thou wilt have had
egli avrà avuto, he will have had
noi avremo avuto, we shall have had
voi avrete avuto, you will have had
essi avranno avuto, they will have had

INDICATIVE MOOD OF THE VERB

Essere (To Be).

Present.

Io sono, I am	*noi siamo*, we are
tu sei, thou art	*voi siete*, you are
egli è, he is	*essi sono*, they are

Past Indefinite.

Io sono stato, stata (fem.), I have been
tu sei stato, -a, thou hast been
egli è stato, he has been
noi siamo stati, -e, we have been
voi siete stati, -e, you have been
essi sono stati, they have been

Imperfect.

Io ero, I was	*noi eravamo* (*ehrah-vàh-mo*), we were
tu eri, thou wast	*voi eravate*, you were
egli era, he was	*essi èrano*, they were

Pluperfect.

Io ero stato, -a, I had been
tu eri stato, -a, thou hadst been
egli era stato, he had been
noi eravamo stati, -e, we had been
voi eravate stati, -e, you had been
essi èrano stati, they had been

Past Definite.

Io fui (*foo-ee*), I was	*noi fummo*, we were
tu fosti, thou wast	*voi foste*, you were
egli fu, he was	*essi fùrono*, they were

Second Pluperfect.

Io fui stato, -a, I had been
tu fosti stato, -a, thou hadst been
egli fu stato, he had been
noi fummo stati, -e, we had been
voi foste stati, -e, you had been
essi furono stati, they had been

Future.

Io sarò, I shall be	*noi saremo*, we shall be
tu sarai, thou wilt be	*voi sarete*, you will be
egli sarà, he will be	*essi saranno*, they will be

Second Future.

Io sarò stato, -a, I shall have been
tu sarai stato, -a, thou wilt have been
egli sarà stato, he will have been
noi saremo stati, -e, we shall have been
voi sarete stati, -e you will have been
essi saranno stati, they will have been

NOTE. The compound tenses of the verb *èssere* are formed with the same verb *essere* and *not* with *avere*: *Io sarò stato* (literally, I shall be been), I shall have been.

EXERCISE VIII.

The verbs *èssere* and *avere*, conjugated in the *interrogative*, *negative*, and *interrogative-negative* forms.

Egli ha. Egli non ha. Ha egli? Non ha egli? Essi avevano. Essi non avevano. Non avevano essi? Non hanno essi avuto? No, ma essi avranno. Quando (when) avranno? Quando saranno stati. Non sono essi stati? Essi furono, ma noi eravamo già (already, pron. dgee-àh) stati. Non avrete avuto? Non sarete stati? Non avremo noi? Voi avrete quando sarete, essi avranno quando saranno stati. Hanno avuto? Non avranno? Aveste? Avevate? Furono? Sono? Non sono, ma saranno quando avranno avuto.

KEY TO EXERCISE IV.

1. The friend. I have a friend. Thou hast a rose. He has a daughter. We have a house. The boy has a pen. The sculptor has a statue. The uncle has a brush. The pupil has a book and a pen. You have a sister. They have a horse and a carriage.

2. The boys have a knife and a pen-knife. You have the envelopes and the pens. The pupils have the envelopes and the books. The sculptors have the statues. The uncles have the houses. The boy has the roses. The friends have the birds, the horses, and the carriages.

KEY TO EXERCISE V.

A hat of silk (silk hat). The statue of the sculptor. The physician of the house. The envelope of the letter. We have received a letter from Paris. From London to Paris, and from Paris to Rome. The books of the pupils are on the table. The gentleman and the lady are in the garden of the sculptor. The boys have received a present. The daughter of the physician has received a ring of gold (gold ring) The friends have bought a house with the money received from Rome. The letters for the lady are on the table in the room of the boys.

KEY TO EXERCISE VI.

Some horses for the carriages. Some roses in the garden. The ladies have some roses. We have received some presents. The boy had some books. He bought some envelopes and pens for some pupils. Have they many horses? The ladies have received some letters from Paris. The sculptor had horses, carriages, houses, and gardens.

FRENCH

Continued from page [illegible]

By Louis A. Barbé, B.A.

DEMONSTRATIVE PRONOUNS

1. The Demonstrative pronouns (*pronoms démonstratifs*) are:

ce, it, that;
ceci, *cela*, this, that;
celui (m.), *celle* (f.), that, the one;
ceux (m.), *celles* (f.), those;
celui-ci (m.), *celle-ci* (f.), this, this one, the latter;
ceux-ci (m.), *celles-ci* (f.), these, the latter;
celui-là (m.), *celle-là* (f.), that, that one, the former;
ceux-là (m.), *celles-là* (f.), those; the former.

2. *Ce* as a demonstrative pronoun is used either (*a*) before *être* (which may be preceded by a third person singular of *pouvoir* and *devoir*), or (*b*) as antecedent of the relative pronoun, the two together meaning "what," and *ce qui* being used as subject, whilst *ce que* is used as object:

c'est lui, it is he ;
ce peut être lui, it may be he ;
ce doit être lui, it must be he.

Ce qui est vrai n'est pas toujours agréable, what is true is not always pleasant : *ce que vous m'avez dit est-il vrai?* Is what you have told me true ?

3. *Ce* is used instead of *il, elle, ils, elles* before the verb *être*, when that verb is followed by a noun having an article, a demonstrative adjective, or a possessive adjective before it :

Qui est ce monsieur? C'est le père de mon ami, Who is that gentleman ? He is my friend's father ;

Qui est cette demoiselle? C'est ma sœur, Who is that young lady ? She is my sister ;

Qui sont ces messieurs? Ce sont des amis, Who are those gentlemen ? They are (some) friends.

4. When the noun which follows *être* is not accompanied by an article, etc., it has the value of an adjective, and the verb is then preceded by *il, elle, ils, elles* :

Il est soldat, he is a soldier ;

Elles sont institutrices, they are governesses.

5. When a third person singular of "to be" is preceded by "it," and followed by an adjective, the "it" is rendered by *il* if the adjective applies to a statement that is going to be made, and by *ce* if it applies to a statement that has just been made :

Je ne le connais pas, c'est vrai, I do not know him, it (that) is true ;

Il est vrai que je ne le connais pas, it is true that I do not know him.

6. *Ceci*, this, and *cela*, that (contracted into *ça* in ordinary conversation) do not refer to any noun mentioned before ; they can only be used in connection with objects, and not persons ; and they have no plural : *Ceci* refers to the nearer object pointed out, and *cela* to the more remote :

Je n'aime pas ceci, donnez-moi cela, I do not like this, give me that.

7. *Ceci*, like "this," in English may refer to a statement that is going to be made ; and *cela*, like "that," to a statement that has just been made :

Retenez bien ceci : Le pain que nous gagnons est le meilleur, bear this well in mind (lit., retain this well) : the bread we earn is the best.

La pratique rend maître, n'oubliez pas cela, practice makes perfect, do not forget that.

8. *Celui, celle, ceux, celles*, without either *ci* or *là* added to them, are used only in two constructions : 1st, before a relative pronoun ; 2nd, before the proposition *de*. The latter construction renders the English possessive :

J'aime mieux votre livre que celui que j'ai, I like your book better than the one I have ;

Je l'aime mieux que celui de votre frère, I like it better than your brother's.

POSSESSIVE PRONOUNS

1. Possessive pronouns (*pronoms possessifs*) of which the agreement, like that of the possessive adjectives, is with that which is possessed, and not with the possessor, are :

	Mas. Sing.	Fem. Sing.	
1st per. sing.	*le mien,*	*la mienne ;*	mine
2nd per. sing.	*le tien,*	*la tienne ;*	thine
3rd per. sing.	*le sien,*	*la sienne ;*	his, hers
1st per. plur.	*le nôtre,*	*la nôtre ;*	ours
2nd per. plur.	*le vôtre,*	*la vôtre ;*	yours
3rd per. plur.	*le leur,*	*la leur ;*	theirs

	Mas. Plur.	Fem. Plur.	
1st per. sing.	*les miens,*	*les miennes ;*	mine
2nd per. sing.	*les tiens,*	*les tiennes ;*	thine
3rd per. sing.	*les siens,*	*les siennes ;*	his, hers
1st per. plur.	*les nôtres,*	*les nôtres ;*	ours
2nd per. plur.	*les vôtres,*	*les vôtres ;*	yours
3rd per. plur.	*les leurs,*	*les leurs ;*	theirs

2. Possession is also expressed by means of the verb *être*, followed by the preposition *à* and a disjunctive personal pronoun :

Ce cheval est à lui, that horse belongs to him

There is, however, a difference between *à moi*, etc., and *le mien*, etc. Ownership, and nothing else, is implied by *à moi*, etc., whilst *le mien*, etc., is used to distinguish the ownership of one object from that of others :

Cette bague est à moi, That ring belongs to me ;

Cette bague est la mienne, That ring is mine (the others are not).

3. The English expression "of mine," etc., is rendered, not by the possessive pronoun, but by the possessive adjective :

He is a friend of ours, *C'est un de nos amis*.

4. *À moi, à toi*, etc., are used with the other possessives, both adjectives and pronouns, to emphasise them :

Est-ce de ma faute, à moi, qu'il n'ait pas réussi?

Is it *my* fault if he has not succeeded ?

5. *A moi, à toi*, etc., preceded by *ce* + *être* and followed by *a* or *de* with an infinitive, form two idiomatic expressions expressing respectively duty, province, privilege, etc., and turn :

C'est a vous à commander, c'est à lui a obéir

It is your province to command, it is his duty to obey.

C'est à vous de jouer, it is your turn to play

Exercise XVII.

1. This pen is good, but that is better.
2. She has shown (*montré*) me her hat and her sister's.
3. I like ours better than theirs.
4. If it is not he, it is his brother.
5. Who are those young ladies ? They are our cousins.
6. Is this gentleman a barrister (*avocat*)? No ; he is a doctor (*médecin*).
7. He is one of our most distinguished (*distingué*) doctors.
8. I do not know that gentleman ; I have seen him once or twice, it is true, but I have never spoken to him.
9. It is true that we have never spoken to him, but we know (*connaissons*) him very well by sight (*de vue*).
10. Have you done that ? No, it was (is) not I, it was he.

11. If you have any finer engravings (*gravures*, f.), show them to me ; I do not like these.

12. What you have just read (*venez de lire*) is very interesting, but it is not true.

13. This room is smaller than ours ; it is the smallest in the whole house.

14. Give me another handkerchief, please (*s'il vous plaît*) ; I have lost mine.

15. Our flowers are beautiful, your sister's are still (*encore*) more beautiful, but yours are the most beautiful.

16. That ring is not mine, I have none ; it belongs to a friend (f.) of mine.

17. It is not *her* ring that she (*qu'elle*) has lost (*perdue*) ; it is mine.

18. Whose turn is it to play ? It is yours.

KEY TO EXERCISE XV.

1. Je cherche mon livre et mes plumes.
2. Vous avez parlé à mon frère et à ma sœur.
3. Il a donné un cadeau à son ami.
4. Il me cherche.
5. Elle vous parle.
6. Nous lui avons donné une montre.
7. Il ne leur parle pas.
8. Leur a-t-elle donné un cadeau ?
9. A-t-il trouvé sa montre ?
10. Je te donne cela, me dit-il.
11. Donnez-le-moi, nous dit mon père.
12. Achète toi un parapluie.
13. Nous nous levons tous les jours à sept heures.
14. Ils ne se couchent jamais avant onze heures.
15. Nous le leur donnons.
16. Elle vous la prête.
17. Il nous en a donné.
18. Vous nous en avez parlé.
19. Si vous avez de l'argent, donnez-lui-en.
20. Ne lui en parlez pas.
21. Nous ne nous y opposons pas
22. Si vous cherchez vos gants, les voici.
23. Vous vous trompez.
24. Ils se flattent.

KEY TO EXERCISE XVI.

1. Ils sont contre moi et pour eux.
2. Elle ne se fie pas à lui.
3. Qui avez-vous vu ? Lui.
4. Qui leur a répondu ? Eux.
5. Qui est là ? C'est moi.
6. Nous irons ensemble, toi et moi.
7. Il nous a parlé, à lui et à moi.
8. Nous y avons été plus souvent qu'eux.
9. Elle est plus intelligente que lui.
10. Eux, que nous croyions nos amis, nous ont trahis.
11. Il travaille, lui, mais toi, tu ne fais que jouer.
12. Lui dire une telle chose !
13. Eux ont fourni l'argent, lui a bâti la maison.
14. Si vous ne me croyez pas, moi, le croirez-vous, lui ?
15. Cet enfant a écrit la lettre lui-même.
16. Elles m'ont dit elles-mêmes qu'elles viendraient ce soir.
17. Ils ne sont jamais chez eux le soir.
18. Chacun pour soi et Dieu pour tous.

NOTE. The next lesson in GERMAN appears in the succeeding instalment of the Language section.

STRESS DIAGRAMS FOR BEAMS

Combined Diagrams. Rolling Loads. Continuous Beams. Compound Girders. Plate Girders. Columns and Stanchions

Group 20

MATERIALS & STRUCTURES

15

STABILITY OF STRUCTURES
continued from page [illegible]

By Professor HENRY ADAMS

Combined Diagram for Irregular Loading. When a beam or girder is irregularly loaded with concentrated loads it is not necessary to work out the effect of each load separately, as in page 1987. Both the bending moments and the shearing stresses can be very neatly shown upon a single diagram, as in **140**. Upon a line indicating the girder draw force lines indicating the loads and reactions, then number the spaces into which the length is separated by the force lines, these numbers being shown in circles for distinction. Produce the lines downwards, and upon the right-hand line mark off the loads to scale. The first load of 2 tons is known as force 1–2, being named by the numbers of the spaces it separates, and is marked on the right-hand line by the distance from 1 to 2. Load 2–3 of 5 tons, and load 3–4 of 3 tons are set out similarly. Then a pole, O, is selected at a distance of, say, 10 ft. from the load-line, using the scale to which the girder was drawn. The pole is then joined to the points in the load-line by vectors. The bending-moment diagram is drawn parallel to these vectors, beginning with line 1 across space 1, started at any point on the left-hand line. Then, continuing it with line 2 across space 2, line 3 across space 3, and line 4 across space 4, joining the extremities of the bending-moment diagram by a line across space 5, a vector is then drawn parallel to it from the pole giving point 5 on the load-line, and consequently fixing the amount of each reaction, or load on support, 4–5 and 5–1.

Details of the Combined Diagram. The bending-moment diagram is called a funicular polygon (Latin *funis*, a cord), because if a cord or chain were fixed at the two extremities and the given weights hung on at the respective points under the load, the cord would take the shape given by the funicular polygon. If the girder has been drawn to a scale of $\frac{3}{8}$ in. to 1 ft., and the load-line to a scale of $\frac{1}{4}$ in. to 1 ton, the polar distance being 10 ft., the vertical ordinates on the bending-moment diagram will be to a scale of $\frac{1}{10}$ of $\frac{1}{4}$ in. to 1 ton-foot, or 40 ton-ft. to 1 in. The shearing stresses will be shown by drawing a horizontal line from point 5 on the load-line as a base, and then projecting from the other points as shown. The vertical ordinates of shearing stress will be to the same scale as the load-line—say, $\frac{1}{4}$ in. to 1 ton, or 4 tons to 1 inch. If the load of 5 tons had been spread over a distance of, say, 4 ft., a slight modification would show the alteration produced in the bending-moment diagram, as in **141**. Lines are drawn down from the ends of the load W, spread over the distance z, and their intersections with the lower outline of the diagram are found by a straight line upon which a parabola is constructed having a depth of $\frac{Wz}{8}$ to the scale of 40 ton-ft. to 1 in. The shearing stresses will also undergo modification as shown.

Rolling Loads. Girders for bridges, travelling cranes, etc., are subject to rolling loads. The simplest case is that of a concentrated load coming on to a girder from one end and travelling along it. In **142** is shown by full lines the bending-moment diagram for the load in its given position, and by dotted parabola the range that would be produced by taking the maxima throughout the travel. Similarly, **143** shows by full lines the shearing stresses with the load in *its given position, and by dotted semi-parabolas* with the vertices at each abutment the shearing stresses produced by taking the maxima throughout the travel.

Continuous Beams. When a beam is continuous over two or more equal spans the pressure upon the supports from a uniformly distributed load is not uniform. This is proved by what is called the "Theorem of Three Moments"; but it will be sufficient to give the results, as in the following table, for equal spans uniformly loaded, the load on each span being unity, and the supports perfectly level and rigid.

No. of Spans.	Abutments	1st Pier from each end.	2nd Pier from each end.
2	·375	1·25	...
3	·4	1·1	..
4	·393	1·143	·93
5	·394	1·131	·989

When the number of spans exceeds five, the loads may be taken on the end supports as for five, and the remaining supports may be considered as carrying unity loads without much error. Putting it another way, if a beam continuous over two equal spans carry a uniformly distributed load, five-eighths of the total load will rest upon the central support and three-sixteenths upon each of the abutments; or, if continuous over three equal spans, $\frac{11}{10}$th of the load will rest upon each of the inner supports and $\frac{4}{10}$th upon each of the abutments. Testing the theory by means of a lattice girder and reciprocal diagrams, it is found that when the distribution of loading is altered by raising or lowering the supports the minimum stresses exist in the girder with the above distribution.

Beam with Fixed Ends. When the ends of a beam are sufficiently fixed it is equivalent to one span of a continuous beam, as in **144** under a concentrated load, and 145 under a distributed load. The end spans are usually merely supported on the abutment, but continuous towards the next span; they are, therefore, in the condition of 146 for concentrated loads and 147 for distributed loads.

Compound Girders. *Compound girders* is the name given to those beams composed of one or more rolled joists with one or more plates added to the flanges. The simplest case is 148, where a single plate is added to the compression flange, and others are shown in 149 and 150, but it is always better to use plain rolled joists out of stock where possible, to avoid both the cost of riveting and the delay of waiting for it to be done.

Rolled Joists with Separators. When two or more rolled joists are used side by side, it is convenient to bolt them together by means of bolts passing through the webs and through cast-iron distance pieces or separators, as in 151, to fix them at the required spacing. The holes, being through the web, do not reduce the theoretical strength, and virtually increase the practical strength by compelling the joists to share the load equally where circumstances may throw rather more upon one of them.

Plate Girders. Before the advent of rolled joists it was customary to build up girders by riveting together wrought-iron plates and angle-irons, as in 152 and 153, and they are still made in this form of steel when rolled joists cannot be obtained of sufficient size. The webs may be of solid plate or of lattice bars arranged in various ways. Plate web girders with single webs, or box girders with double webs, are suitable for spans up to 50 ft., but beyond that lattice bars are more economical, as they can be proportioned more closely to the stress upon them. The bending moment at any point of a plate girder divided by the depth from centre to centre of the flanges gives the stress in each flange at that point, and the stress divided by the working allowance per square inch gives the number of square inches required in the effective sectional area. In the compression flange the effective area will be gross area, as the rivets fill the holes and offer solid resistance. In the tension flange, however, the rivet holes across the section must be deducted, as they reduce the tensile strength by the amount cut away. It thus happens that in wrought iron, with an allowance of 4 tons per square inch compression and 5 tons per square inch tension, the two flanges will be about equal, the less stress coming on the gross area and the greater stress upon the net area. In steel, when the allowance is equal in tension and compression a slight reduction may be made in the area of the compression flange. It is usual to count one side of the angle-irons as part of the flange.

Use of Parabola in Designing. With a rolled joist there is an inevitable waste of metal, because the section is uniform throughout, and must be sufficient to resist the maximum bending moment, which occurs at one point only. With girders having the flanges composed of several plates it is possible to adjust the sectional area very closely to the required amount, by letting the inner plates run through and stopping off the outer plates, as in 164.

Cast-iron Stanchions. Cast-iron solid stanchions of ✚ or H section are now only used in small and unimportant work. They may be calculated by Gordon's formula

$$W = \frac{6s}{1 + \frac{3l^2}{800d^2}},$$

where W = safe load in tons, s = sectional area in square inches, d = least diameter in inches, l = length in inches; but it will, in general, be sufficient to proportion the sectional area as follows:

Up to	8	diameters	long	5	tons per	sq. in.
,,	10	,,	,,	4	,,	,,
,,	12	,,	,,	3	,,	,,
,,	15	,,	,,	$2\frac{1}{2}$	,,	,,
,,	18	,,	,,	2	,,	,,
,,	24	,,	,,	$1\frac{1}{2}$	,,	,,
,,	30	,,	,,	1	,,	,,

Cast-iron Hollow Columns. These may be calculated by Gordon's formula as above, but with a constant of $\frac{1}{600}$ instead of $\frac{3}{800}$, or with a thickness of $\frac{1}{12}$ diameter the safe load may be taken as:

10 to 15	diameters	long	4	tons per sq. in.
15 ,, 20	,,	,,	3	,, ,,
20 ,, 25	,,	,,	2	,, ,,
25 ,, 30	,,	,,	$1\frac{1}{2}$	,, ,,

Rolled Joists as Stanchions. Only a few of the ordinary sections of rolled joists are suitable for stanchions, owing to the great difference in the moment of inertia in the two directions. For instance, the 14 in. by 6 in. by 57 lb. section has a vertical moment of 520·65 and a horizontal moment of 30·73, whereas for maximum efficiency it should be equal in both directions. One of the best sections is the 9 in. by 7 in. by 58 lb., which has moments of inertia of 216·81 and 46·59 respectively. The most suitable sections are the *differdange* or broad flange beams made by H. J. Skelton & Co. In these up to 12 in. deep, the width of flange is equal to the depth of beam, and the larger sections have a constant width of 12 in. The carrying capacity, with an axial load, is usually determined by the Rankine-Gordon formula for struts,

$$W = \frac{fA}{1 + \frac{l^2}{cr^2}},$$

where W = safe load in tons, f = maximum working stress in compression on short specimen in tons per square inch = 6 for mild steel, A = sectional area in square inches, l = length in inches, c = constant = 36,000 for ends flat and fixed, 24,000 for one end rounded or free to bend, and 18,000 for both ends rounded, r = radius of gyration.

Radius of Gyration. The objection to the simple Gordon formula is that the calculated strength from the ratio of length to least diameter does not agree with experiment so well as the ratio of length to radius of gyration

154 Use of parabola in designing

which is substituted in the Rankine-Gordon formula. The radius of gyration is the square root of the quotient after dividing the moment of inertia by the sectional area, or

$$r = \sqrt{\frac{I}{A}};$$

but as the square of the radius of gyration is required in the formula it may be stated as

$$r^2 = \frac{I}{A}.$$

Calculation of Strength. Take, for example, 9 in. by 7 in. by 58 lb. rolled steel joists. The sectional area is 17·05 sq. in., the vertical or greatest moment of inertia is 216·81 in square inch units, and the horizontal or least moment of inertia is 46·59 sq. in. units; then,

$$r^2 = \frac{I}{A} = \frac{216{\cdot}81}{17{\cdot}05} = 12{\cdot}7,$$

and

$$\frac{46{\cdot}59}{17{\cdot}05} = 2{\cdot}73.$$

Assume the stanchion to be 12 ft. long, then

$$W = \frac{fA}{1 + \frac{l^2}{cr^2}} = \frac{6 \times 17{\cdot}05}{1 + \frac{144^2}{36000 \times 12{\cdot}7}} = 97{\cdot}8 \text{ tons}$$

safe axial load if the stanchion is prevented from bending in the plane of either flange, or

$$\frac{6 \times 17{\cdot}05}{1 + \frac{144^2}{36000 \times 2{\cdot}73}} = 84{\cdot}5 \text{ tons}$$

if free to bend in either direction. The tabular value of ultimate strength in the manufacturers' catalogues is given as 338 tons, with a factor of safety of 4 for stationary loads and 6 for live loads, making the safe loads respectively $\frac{338}{4} = 84{\cdot}5$ tons and $\frac{338}{6} = 56{\cdot}3$ tons, showing the agreement of the tabular load with calculation.

Limiting Stress per Square Inch. It must be observed that the greatest safe loads according to the direction of bending being 84·5 tons and 56·3 tons respectively, the limiting stress per square inch for a stanchion of *this section and length* will be $\frac{84{\cdot}5}{17{\cdot}05} = 4{\cdot}96$ tons, and $\frac{56{\cdot}3}{17{\cdot}05} = 3{\cdot}3$ tons.

Non-axial Loads. There are very many cases in practice where the load is not axial, but is applied at one side of the rolled joist section, as where a stanchion is continuous through one or more floors, and the floor girders are attached by brackets or angle-irons to the flange or web of the stanchion. In these cases, a bending moment is caused in addition to the direct stress due to the load. It is a popular fallacy that when the girder is attached to the web of the stanchion the load is transmitted down the centre, and no bending moment results. This, however, is contrary to fact, and although the leverage to the centre of the bearing may not exceed 2 in., a very serious additional stress is put on the stanchion, and the tendency to bend is in the direction of the least moment of inertia or radius of gyration. Taking the same rolled joist as before, if a load of 17 tons be applied at a distance of 2 in. from the centre of web, the bending moment will be 17 × 2 = 34 ton-inches, and the compressive stress on the edges of the flanges will amount to $\frac{W}{A} + \frac{M}{Z}$, where W is the load in tons, A the area in square inches, M the bending moment, and Z the modulus of section, often wrongly called in many catalogues, "the moment of resistance in square inches." $Z = \frac{I}{y}$, and in the present case of 9 × 7 stanchion loaded on the web,

$$Z = \frac{46{\cdot}59}{3{\cdot}5} = 13{\cdot}31.$$

Then

$$\frac{W}{A} + \frac{M}{Z} = \frac{17}{17{\cdot}05} + \frac{34}{13{\cdot}31} = {\cdot}997 + 2{\cdot}554 = 3{\cdot}551$$

tons per sq. in.

But it has already been shown that the limiting stress on this stanchion when free to bend in this direction is 3·3 tons per square inch, so that the stress with the load of 17 tons is just over the desirable limit. On the other hand, the load may be carried from one flange of the stanchion so as to utilise the greatest moment of inertia. Then, allowing half the depth of section, 4½ in., and 2 in. more to centre of bearing surface, the bending moment will be 6·5 × 7 = 110·5 ton-inches. The modulus of section will now be

$$Z = \frac{I}{y} = \frac{216{\cdot}81}{4{\cdot}5} = 48{\cdot}18,$$

and

$$\frac{W}{A} + \frac{M}{Z} = \frac{17}{17{\cdot}05} + \frac{110{\cdot}5}{48{\cdot}18}$$

$$= {\cdot}997 + 2{\cdot}293 = 3{\cdot}29 \text{ tons per sq. in.},$$

but the allowable stress in this direction is 4·97 tons per square inch, so that it leaves an ample margin of safety, although the load is further from the axis of the stanchion.

Stanchions for Heavy Loads. When the load applied at the side of a stanchion exceeds 20 tons, it will in general be necessary to use a built-up section, and care should be taken to provide the requisite area with the least amount of riveting. It should also be noted that the material is more effective when disposed round the circumference rather than towards the centre; thus, two channels and two plates, as in **155**, or three rolled joists, as **156**, form economical sections. The exigencies of space, however, sometimes compel the opposite extreme to be followed, and a solid section becomes necessary.

PETTY CASH

Methods of Recording Petty Cash Items. Tracing Errors. The Memorandum Petty Cash Book. Trade Expenses. The Imprest System

Group 7

CLERKSHIP

15

Continued from page 1969

By A. J. WINDUS

IN resuming our study of the synopsis on pages 1750 and 1751 it is desirable to examine transaction (*a*) in its relation to the petty cash book. There are two ways of treating this book. By some it is regarded as a mere memorandum book in which to enter day by day, or whenever the notion seizes them, payments which are considered too insignificant for individual entry in the cash book. At the end of each week, month, or other period, these payments are summarised, and the summary figures carried to the cash book. Thus the table on page 1968 informs us that for the week ended Aug. 6th, 1904, certain trade expenses totalled £1 11s. 2d. The amount is accordingly shown on the credit side of the cash book on the succeeding page to that on which the table appeared, and the details have been noted in a memorandum book as follows:

1904			£	s.	d.
Aug. ..	2	Stamps		5	
	3	Fares, West End			6
		Gratuity to Carman ..			2
		Book of telegram forms ..		10	2
	4	Blotting paper		1	
		String			8
		Crate wood for cases ..		7	2
	5	Advt. in P.O. Directory ..		5	
	6	Carr. on goods from Lebus		1	6
			£1	11	2

Petty Cash Items. This method of recording petty cash expenditure is an improvement upon the former practice of passing petty cash items through the journal. There is, however, a serious objection to the memorandum petty cash book. It constitutes a weak spot in any system of bookkeeping because it is not properly interlinked with the other counting-house records. Books of original entry are temporary halting-places for items on their way to the ledger. It is here that transactions and transfers have debit and credit values assigned to them, and these values must be passed to their final resting-place in the ledger. The penalty for default is that the ledger will not balance, and a not less serious consequence is that the ledger will be destitute of information which it ought to contain.

Items in books of original entry may be compared to travellers who reach a common goal by different roads. Their entry into the sectional journals marks the penultimate stage of their journeyings. It is here, also, that they are marshalled into two great classes—debits and credits. From this time onwards the debits are not allowed to mingle with the credits, but must keep to one side of the road while the latter take the other side. Even when they arrive at their journey's end, the two classes will remain separate—debits to the left, credits to the right of the ledger folios.

A further rule which is derived from the classification just referred to is that no debit will be allowed to enter upon this stage unaccompanied by its proper credit, and vice versâ. The rule is most stringently enforced, and admits of but two exceptions, which do not, however, vitiate the underlying principle, but merely modify its application. The first exception is designed to meet the case of a number of debits equivalent in the aggregate to a single credit. A clear indication of the bond that unites them is accepted in lieu of literal compliance with the rule. First the debits are conveyed one by one to their destination in the ledger, and then the sole credit is transported thither. The other exception is permitted in the case of a number of credits equivalent in the aggregate to a single debit, and the procedure is similar to that described for the first exception.

Tracing Errors. Hence the regular admission of items into a journal is in itself a sort of guarantee that they will find their way in due course to the ledger. If they are posted wrongly, or not posted at all, the two sides of the Trial Balance will fail to agree, search will be made for the difference, and errors and omissions will be laid bare. For all that, a trial balance is not an infallible test of the accuracy of the bookkeeping. It will not, for instance, reveal an error in posting an amount to the debit of A's account which should have gone to the debit of B's account, and it is often powerless against what are called compensating errors. Thus, if the credit balance on Bills Payable account in the epitome at page 1750 were extracted as £55 14s. 11d., while at the same time the debit balance on Salaries and Wages account were set down as £11 10s., the Trial Balance—being correct in all other respects—would show an absolute agreement between the debit and credit totals, and yet in preparing a Balance Sheet and Profit and Loss account therefrom the liability under the head of Bills Payable would be overstated by 10s., as would also the business expenses under the head of Salaries and Wages. The one error compensates the other. The risk of posting items to wrong accounts cannot be wholly avoided, but the true safeguard against such errors remaining undiscovered is the careful checking from time to time of all ledger postings by calling them over with the original entries in the journals. Experience has proved this to be a wise precaution, but it is one that is too often neglected by bookkeepers.

Memorandum Petty Cash Book. Now, the memorandum petty cash book is not a book of original entry in the technical meaning of the term. It bears the same relation to the cash book—the real book of original entry for the item of £1 11s. 2d.—as the waste book does to the journal. Its entries may affect the ledger indirectly because of the difficulty of verifying the cash balance if they were not taken into account, but in practice the keeping of a memorandum petty cash book too often resolves itself into an attempt, or a series of attempts, to overcome the hiatus between the amount of cash that ought to be in hand according to the cash book and the amount actually present in the cash-box. The cashier is in truth the victim of a complicated system of dealing with the cash and of recording cash transactions.

Not only is it very easy under such conditions to lose sight of, or to forget to note down, an item in the memorandum book, but there is a temptation to "lump" together items which really belong to different accounts. The correct allocation of petty items is a tedious, and may seem a trivial task, in view of the smallness of the weekly or monthly totals. Nowadays, however, the margin of profit is so narrow, and competition so keen, that it becomes imperative to analyse expenditure exhaustively, so that waste and extravagance may be detected and for the future prevented. Let us see, for example, how the distribution of petty expenditure would be made in the case before us.

A summation of the items in the memorandum cash book for the week ended August 6th, 1904, would be made. Then the total of £1 11s. 2d. would be apportioned as under:

	£	s.	d.
Postages and telegrams ..		15	2
Packing materials		7	10
Carriage		1	6
Advertising		5	0
Printing and stationery ..		1	0
Trade expenses			8
	£1	11	2

Instead of entering one item of £1 11s. 2d. in the cash book, we should now enter six items aggregating that amount, writing opposite each item the name of the account to which it belonged. Finally, the items would be posted to their appropriate accounts in the ledger.

Trade Expenses. It may be stated in passing that Trade (or Office) Expenses account is an account of miscellaneous items, trifling in amount and of infrequent occurrence. The total amount standing to the debit of Trade Expenses account at the end of a given period represents, in fact, a residuum of expenditure which cannot fairly be charged to specific expense accounts, having been incurred for the benefit of the business as a whole.

The petty cash book has always been the subject of a certain amount of misconception in the minds of many people because of its title. It is said—but the statement is inexact—that the petty cash book is a record of items which are too insignificant to be passed through the cash book. That may have been so originally, but to-day we find the petty cash book performing the functions of a true cash book—items appearing therein of salaries, wages, commissions, travelling expenses, and the like, which represent quite respectable sums of money, as well as items of genuine petty expenditure. Perhaps, if the word "office" were substituted for the word "petty," so that we might distinguish the cash registers as bank cash book and office cash book respectively, we should get rid of the idea that the petty cash book is of merely minor importance.

It is this idea which for a long time prevented the petty cash book being treated as a journal; but when, on the one hand, the need for analysing the petty cash became apparent, while, on the other hand, bookkeepers were dismayed at the extra labour involved, the possible direct relationship of the petty cash book to the ledger was inquired into more closely. The result was that changes and developments have occurred in the character of the former, culminating in the analysis petty cash book as illustrated at page 403.

The Imprest System. Before dealing with that, however, let us briefly consider one or two of the other methods of recording petty cash transactions which are in use at the present time. First, there is the imprest system. The petty cashier receives an open cheque for a round sum of, say, £10, which amount the cashier enters on the credit side of the cash book, charging petty cash account therewith. Presently the ledger keeper opens an account for petty cash with the debit of £10 posted from the cash book. The petty cashier having cashed the cheque, puts the proceeds in the cash-box. From the fund thus provided he makes payments not exceeding the authorised limit for any one payment. At the end of the month—or earlier, should his balance happen to be running low—he totals the payments made since he received his latest advance, and rules the amount off thus:

1904 Jan. 1	Stamps			5
2	&c.			&c.
&c.				
	Total for January	£8	14	3

His next care is to analyse the total, which done, he takes his analysis together with vouchers in support of his expenditure, to the cashier, who examines the figures with the vouchers, and, finding them correct, in due course hands the petty cashier an open cheque for the exact sum stated to have been expended—namely, £8 14s. 3d. The analysis is retained by the cashier, who, instead of entering £8 14s. 3d. as a payment, copies from the analysis into the cash book the several sums that go to make up the amount of the cheque, and from the cash book these items would eventually be posted to the ledger. The petty cashier, having cashed the cheque for £8 14s. 3d., adds the proceeds to the money in the cash-box. If no payments have been made in the meantime, it will be found that the cash in hand has now been restored to its original amount of £10.

At the end of January there should have been £1 5s. 9d. in the cash-box (£10 less £8 14s. 3d.), therefore an addition of £8 14s. 3d. thereto would replace the petty cashier at the beginning of February in the position he occupied on January 1st, of a debtor to his employers for the sum of £10 advanced for petty cash.

From the new fund thus formed he continues to make payments until the time comes to approach his chief for more money, when the same routine is observed as before.

As a consequence of the method now explained, the registration in the petty cash book of cheques received by the petty cashier is rendered unnecessary. There is no difficulty in testing the cash balance, because this must always coincide with the difference between the recorded current expenditure and the floating debt of £10. Thus, if up to February 15th the petty cashier has expended, according to his cash book, £5 9s. 2d., he ought to have £4 10s. 10d. in hand.

Advantages of the Imprest System. The advantages of this method from the administrative point of view are that it establishes a salutary control over the petty cash expenditure, and that it ensures, if faithfully carried out, the lodgment intact of all sums from outside sources which have been registered in the cash book. In the latter respect the system is similar to that recommended on page 977, but the petty cash book differs from that shown on page 403 in that the analysis figures are not posted to the ledger direct, but through the cash book, whereas the columnar totals of our tabular petty cash book are posted direct.

There is, however, nothing to prevent the petty cashier, with his chief's permission, making the periodic analyses in the petty cash book itself, thus enabling the ledger keeper to use it as a book of original entry from which the ledger postings could be made. If this were done, the cashier would merely enter in the cash book the amounts of the petty cash cheques, against which references to the petty cash book would be inserted in the folio column. The inquirer, on turning to the places in the petty cash book which had been pointed out in the cash book, would find that the amounts entered in total in the latter had been dealt with in detail in the former. But the initial £10 would be posted to the ledger direct.

The petty cashier might go even further than this by approximating the form of his cash register to that of the tabular petty cash book through the addition of analysis columns. By this means the labour of the monthly dissections of expenditure would be reduced and simplified.

The "cash" columns in the cash book illustrated on page 1969 are indicative of a method of stating cash transactions which has already been dealt with. A variation of the method may be obtained by pressing these "cash" columns into the service of petty cash. This is done by those who deny the utility of a separate book for petty cash. Instead of a single amount for £1 11s. 2d. appearing in the "cash" column as trade expenses for the week ended August 6th, particulars of the items making up that amount would be interspersed among the narratives of other payments, the amounts themselves being entered in the "cash" column. The scheme has at least this advantage over the plan of keeping a memorandum book for petty payments—namely, that by abolishing this book it also destroys the unreal distinction between cash and petty cash, and enables a better control over the cash in hand to be maintained.

Some Disadvantages of the Scheme. The obvious disadvantage of the scheme is that it involves the individual posting of a large number of small amounts which in other circumstances would be summarised, only the sub-totals obtained thereby being posted to the ledger. The difficulty might be partly overcome by reserving an extra column on the credit side of the cash book for petty payments which could be totalled and dissected at convenient intervals, and the resultant figures carried into the "cash" column, from whence they could be posted to the ledger.

We may notice an alternative method to the imprest system of managing petty cash transactions, where moneys from outside sources are banked punctually, and without any deduction. This consists in keeping a separate petty or office cash book ruled with debit and credit columns, wherein all receipts of money from the bank and all payments except those made by cheque are duly recorded. There is no floating balance in this case, but amounts of £5 are drawn from the bank as often as they are wanted, and added to the cash balance. Except that in many cases there are no analysis columns in the petty cash book, this system is identical with that which now falls to be described.

A careful comparison of the various modes of handling and recording cash and petty cash should lead us to give our verdict in favour of the analysis, or tabular petty cash book already mentioned. If we subscribe to the scientific truth that progress is always from complexity to simplicity, then we shall agree that the highest, because the simplest, form of petty cash book which has come within our knowledge is the one shown on page 403. To it, and also to the bank cash book on page 779, the student is now asked to refer.

The Tabular Petty Cash Book. In pursuance of the policy of having every account in the ledger, an account for petty cash has been opened on folio 25 of Messrs. Bevan & Kirk's general ledger. The first item on the debit side is the balance of 10s. as at September 1st, 1905, and the amounts drawn from bank during the month, as ascertained from the bank cash book, follow in chronological order. The result should be a total debit of £90 10s., corresponding with the total of the "received" column in the petty cash book. On the credit side, the total expenditure for the month, as ascertained from the petty cash book, has been posted in one sum—*viz.*, £89 13s. 1d. The account has been balanced off, and the balance of 16s. 1d., which agrees with that shown in the petty cash book, brought down to the October account.

The petty cash account in the ledger is nothing more than an epitome of the petty cash book, and might, therefore, be dispensed with but that it affords a check upon the amounts shown in the "received" column of the petty cash book, and is useful for other reasons. Bearing in mind what was said as to the bank balance and the cash in hand constituting two portions of one fund, we see clearly why the transfer of money from bank to petty cash has the effect of debiting petty cash account and crediting bank account, and nothing further need be said concerning such transfers.

Treatment of Payments from Petty Cash. With regard to payments from petty cash, we notice that these, after being entered in the "paid" column, have been analysed under various heads. It should be pointed out that unanimity among business men in the matter of the particular accounts to which items of expense should be apportioned cannot be expected, and does not exist. But there are some rules which are of general application, and should be adhered to.

An example of what is meant occurs in Messrs. Bevan & Kirk's petty cash book. Under date of Sept. 27th, we have the item "Advertisement for salesman, 3s." It would be wrong, but the mistake is often made, to treat an item of this kind as a debit to Advertising account, because that account is opened for the specific purpose of showing the expenditure incurred in making known the firm's business to the utmost possible extent. What bearing has the advertising for a salesman or clerk upon the increase of business expected to flow from a well-ordered advertising campaign ?

The Ledger Postings. We shall number the money columns to the right of the "paid" column in the petty cash book 1, 2, 3, 4, 5, 6 respectively. It having been shown that the cross-casting of the totals of all these columns is equivalent to the total amount expended, nothing now remains except to note the ledger postings. Jones & Co., Wm. Smith, and the Berlin Manufacturing Company are manufacturers for whom Bevan & Kirk act as agents. Out-of-pocket expenses paid from petty cash, and chargeable to all or any of them, are shown in columns 1, 2, 3, and pains must be taken to see that items are placed in the right columns. The special vice of the columnar system of bookkeeping is the risk of items getting into the *wrong* columns. The references at the foot of columns 1, 2, and 3 inform us that 7s. 2d. has been posted to the debit of Jones & Co.'s account in the general ledger (G.L. 51), 10s. 2d. has gone to the debit of Smith's account (G.L. 53), and 3s. 4d. to the debit of Berlin Manufacturing Company's account on G.L. 55.

The total of column No. 4 has been posted to the debit of Trade Expenses account, and we shall not be slow to admit the utility of the tabular method when we reflect that if all the items had been posted singly they would probably have occupied from forty to fifty lines in the ledger, while, if the petty cash had been summarised, the grouping of all the items would yet have proved a troublesome task.

Postage Column. Column No. 5 is reserved for stamps. By this means a check upon the postboy is established, as will be seen. The monthly total of the postages column appears as a debit on Postages account (G.L. 29). The last column is headed "Sundries," and contains all the items which do not belong to any of the other columns. These are posted, not in total but in detail, and therefore a special folio column is provided to admit of the insertion of ledger references.

We may refer to Transaction (*b*) in the synopsis for the sake of completing our remarks on Bevan & Kirk's postage book.

"Sept. 20, stamps purchased, 5s."

The postage book kept by Bevan & Kirk's junior clerk is a miniature of the firm's petty cash book, and the rules laid down for the latter will apply equally as well to the former. The Postage account in the General ledger already stands debited with £2, and, assuming the stock of stamps to have run out on Aug. 31st, this amount would represent the total debit for September corresponding with the total of the "received" column in the postage book. On the credit side, post the total expenditure for the month as ascertained from the postage book, say £1 19s., balance the account, and bring down the balance of 1s., which should agree with that shown in the postage book brought down to the October account.

"Received" Column of Postage Book. The entries in the "received" column of the postage book represent transfers from petty cash to postages, and may be checked at any time by comparison with the Postage column in the petty cash book. Such transfers have the effect of crediting Petty Cash account and debiting Stamps or Postages account.

The "paid" column of the postage book is analysed under the headings Jones & Co., Wm. Smith, Berlin Manufacturing Company, Office, Sundries.

The procedure as to cross-casting the monthly totals and posting them to their respective accounts in the ledger is precisely the same as that described for Bevan & Kirk's petty cash book.

MAKING A PRINCESS GOWN

The Fastenings. Boning and Linings. The Sleeves and Collar. Trimmings. Lapping Seams. Strappings

By Mrs. W. H. SMITH and AZÉLINE LEWIS

THE front can either be made to button or have an edge to edge fastening. If the former, the inlay must be cut away to within ¼ in. on the buttonhole side, and ¾ in. on the left side for the buttonstand. For the working of buttonholes see the instructions given in boys' tailoring.

If an edge to edge fastening, the inlay must be cut away on both sides to within ⅜ in. The edges must be turned in ⅜ in., and serged to the canvas only, very thickly, then stitched by machine quite close to the edge. The hooks and eyes must be sewn on alternately on both sides, not less than ¾ in. apart. The hooks should be $\frac{1}{16}$ in. in from the edge and the eyes $\frac{1}{16}$ in. out from edge. They must be sewn on strongly with fine thread. Well secure the opening.

We assume the fore parts to be prepared as in previous lesson—it must be remembered that we are giving exceptions only.

Baste all the parts together except the fronts. Be careful to keep waist line to waist line and notch to notch in every instance; if this is not done the back is liable to be passed up or down in the making, thereby destroying the balance and giving a lot of unnecessary trouble to put right.

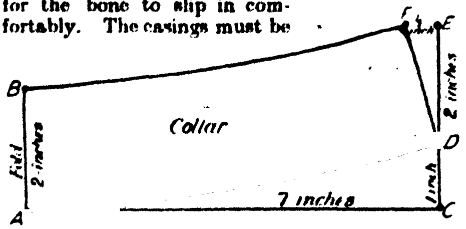
The right half must be basted from bottom to top, and the left from top to bottom—*i.e.*, the curved parts must always be underneath. This also applies to the machining. Baste the seams thickly, as on this largely depends the success of the garment.

The seams after being stitched must be treated in the same manner as the ladies' tight-fitting jacket.

Boning. Put the whalebone in cold water to soak while the seams are being prepared with the casings. Prepare ten or twelve strips of canvas on the bias, 1 in. wide and about 8½ in. long. Baste a strip on each seam, beginning 2½ in. below bust line, and keeping it well eased at the waist; secure to the edges of seams. Now cut the linen through from corner to corner to obtain the bias; cut ten or twelve strips 1½ in. wide and about 8½ in. long, and fold each through the centre. They will now be ¾ in. wide.

Begin with the back; place one of the strips ⅜ in. on either side of the centre of seam and baste, keeping it easy above and below waist, and so on with each strip.

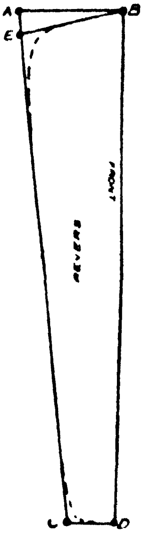
71. SOME STYLES EVOLVED FROM THE PRINCESS GOWN



70. THE COLLAR

The linen must be half back-stitched to the canvas on both sides, leaving sufficient room for the bone to slip in comfortably. The casings must be left free 1 in. at the top and ½ in. at the bottom, and the latter stitched to prevent the bone coming out.

When the bone is sufficiently pliable, pierce holes 1 in. from the top of each piece and ¾ in. from the bottom. They should be ½ in. longer than casing. The ends must be pared round or they will cut through the garment.



72. DRAFTING REVERS

Now take a piece of the bone, and bend it with the thumb and finger to make it curve well in the hollow of waist. Place it in the casing, pushing it down well through the fulness at the waist, and securing it to the casing top and bottom through the perforations, and again 2 in. above the waist line. Sew up the top of casing, and treat all the seams in the same way.

The Darts. The darts must be prepared in the same manner, but the casing must be left free 1½ in. below the top of dart and well eased in the hollow of the waist. Insert the bone and secure the top. Both darts are so treated. The fronts also will require boning for edge to edge fastenings.

Now baste the forearm to side; stitch the seam, open, and press; insert the casing and bone as described for the other seams.

Place a little wadding in the front of armhole, the shape of a dress preserver [69, page 2059]; it must be thinned away at the edge from end to end. Close the shoulder as in previous lesson, then stitch up front as far as seat line; press and finish as before.

We are now ready for the canvas for the bottom of robe. This must be cut the same shape as the gores, and not less than 4 in. deep. Each piece must be basted to its corresponding gore and well secured to each seam.

It can be stitched with as many rows of stitching as preferred, beginning ½ in. below the top of canvas. The stitching adds to the beauty of the robe, providing the rows are kept even. Turn the bottom up and serge to the canvas.

Place a damp cloth over and shrink out all the fulness with a hot iron, lifting the bottom occasionally to let the steam escape.

Having done this, we are ready for the lining.

The Lining. Place waist line of lining to waist line of robe, and secure to each seam. Be sure and put it in "easy" in length and width. Baste the lining to the front under the hooks, keeping it quite easy at that part.

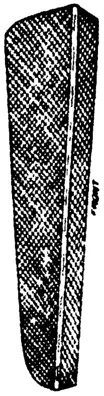
Now baste the lining to the top of inlay at the bottom of robe, and fell.

A wrap about 1½ in. wide should be secured to the left side from the neck to opening; it must be secured here and there to keep in position, and must be pressed and made neat before putting on.

For the sleeve, the reader should refer to the instructions given on page 2056. If preferred, it may be cut off to the elbow and have a gauntlet. In this case, a little more fulness will be required at the elbow, to be eased in [c and d, 71].

The Collar. The collar should be of stiff collar canvas. For the pattern, see diagram 70.

It is advisable to place the canvas between two pieces of thin lining and stitch it all round and through the centre. Allow ½ in. turnings on the cloth; baste to the collar and serge the edges thickly to the lining; mitre the corners to make them thin, and either stretch or nick curved part as from B to F; remove the basting and press.



73. REVERS LINING

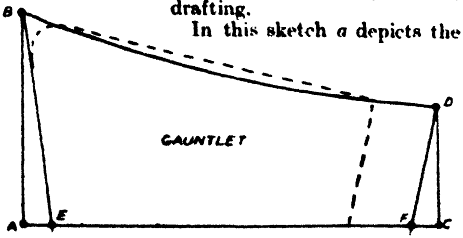
Sew on two hooks and eyes to match the front.

Attach the collar to the centre of back, and the ends even with the fronts. Baste to the neck from the inside, holding it well over the hand. The hollow of the neck should be stretched a little.

It is advisable to sew the collar on by hand, and line either with a piece of the same lining as robe, or with silk. Secure two hangers at the back of armholes, as at I'.

This completes the making of the plain robe, but it can be dealt with in many ways, and converted into various garments—from a dressing to an evening gown, as the following will show.

Diagram 71 presents some gowns for day and evening wear, evolved from the preceding drafting.



74. DRAFTING GAUNTLET

In this sketch *a* depicts the gown of the drafting, fastening at the side, with only graduated strapping on the side-seams of bodice as trimming. If this style is preferred, the centre front must be placed to the fold, and an inlay left on the left fore part from M^b to the bottom. To do this, it will be best to cut the left fore part through the dart and the side nearest armhole separately, so that the inlay can be left on in the cutting.

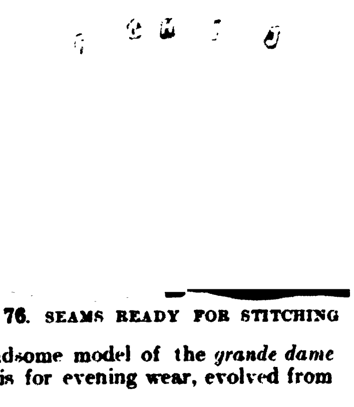
The fastening should have a strapping to hide it, and the right dart must, of course, be strapped to match.

b shows the same gown, with the addition of revers of velvet, edged with silk or gold cord and lace, and a pointed velvet vest-piece at neck and waist, also edged to match.

The sleeves have gauntlet cuffs to correspond, whilst the edge of the skirt is trimmed with a band of velvet, with deep Vandyke lace or passementerie above this, with the points turning upwards. The making of the gown follows the directions already given, the pointed vest-pieces being added before finishing the fronts. The making of cuffs and revers will be considered later.

Another pretty and very favourite style is the corselet skirt, which is also evolved from our drafting. In this case, all that is required is to cut the top to the bust line, or according to the height required, and then curve this as taste and fashion may dictate. Our diagram (*c*) gives a suggestion for such a gown to be worn over a blouse, with straps extending over the shoulders, edged with spotted velvet trimming, which also edges the three shaped tucks at the foot part of skirt. The making of shaped tucks has been described in Dressmaking. They are cut to the shape of the skirt and unlined, the edge being turned up on the right side and neatened with the trimming. The fastening in this model is at the back, but the making is exactly the same as for the front fastenings.

The same model appears in *d* of the diagram, worn with a smart little bolero for out-of-door wear. The sleeves in both models are to the elbow, but we think the student will hardly require to be told that the sleeve of our drafting [59] will do for this, and may be cut any length desired.



76. SEAMS READY FOR STITCHING

On the left, *e* gives a handsome model of the *grande dame* order, which is for evening wear, evolved from our drafting. This is cut to the requisite neck depth, either with or without shoulder straps, and is carried out in velvet of the chiffon or ordinary make, although satin or brocade, or even the finest panne cloth, are equally suitable. It is trimmed at the neck with handsome pointed lace and a fold of tulle.

The skirt is longer than the others, but the manner of obtaining this should present no difficulty to those who have followed this course, as well as that of the Dressmaking, whilst the remarks there given as to the pressing of velvet should be followed in the making of this gown, the very greatest care being necessary.

75. FIRST STAGE OF LAPPING

If satin, brocade, or pile goods be used, shrinking is not possible. The fastening may be accomplished at either back or front, by means of edge to edge fastenings or eyelet-holes and lacing, as preferred. This last dress, whilst not, perhaps, tailor-made in the strict sense of the word, is included here because the making of such a robe in its very simplicity of outline demands those qualities of cut and accuracy, as well as perfection of fit and make, which distinguish the best tailor work.

Having studied the making of the plain garment, we must now turn our attention to the various ways by which it can be adorned—by means of revers, cuffs, strapping, etc. We will, therefore, first consider the revers which trim the bodice of the Princess Robe of *b*, in 71.

Drafting. A piece of paper 18 in. by 6 in. will be required.

Square lines at right angles ½ in. from top and ½ in. from edge.

A to B, 3½ in.; A to C, the length required—in this case 18 in.; C to D, 1 in. Connect B to D, and A to C.

A to E, ¾ in. Connect E to B. Round the corners as in the sketch, or leave them pointed if preferred, as this is a mere question of taste. Cut the pattern round the outline [72].

Materials Required. ½ yd. of velvet, ½ yd. very fine vest canvas, ½ yd. mull muslin. This will leave sufficient for the gauntlets.

Cut the canvas on the bias, allow ½ in. from B to D for turnings. Cut two pieces of muslin for each rever, the same size as canvas; this not only prevents the edges cutting through, but gives a fulness or finished appearance to the revers when in position.

Place the canvas between the muslin and baste together round the edges. Now place a narrow silk stay along the fold of rever as from B to D, taking care not to stretch the fold. A narrow ribbon, ¼ in. wide, makes a good stay [73]. Fold the velvet and cut both revers together, to ensure their being the right shade [see page 864].

Place the front of rever to the fold; allow ½ in. turning round the outer edge. Baste the rever slightly with a fine needle and silk, to keep in position, keeping the velvet easy. Turn in the outer edges and herringbone to the muslin; over-sew the raw edges. Face the rever with silk and trim as desired; it is then ready to be sewn on. *Baste to the bodice ¼ in. from the fold.* [*For position see b*, 71.] *When arranged to satisfaction, secure to the bodice.*

Gauntlet for Princess Robe. For the drafting, a piece of paper 8 in. by 5 in. will be required [74].

Elbow measurement, 12 in. Working scale, half elbow, 6 in. Begin the drafting as for rever. A to B, 3½ in., or depth required. A to C, width of elbow, plus 1 in. (7 in.); C to D, 2 in.; curve from D to B. A to E, ½ in.; C to F, ½ in.; connect E to B and F to D. The broken lines show the turnings, which must be cut as shown, to prevent contraction when put on. The gauntlets are made in exactly the same way as the rever, but the bottoms of the sleeves must be finished off before they are put on.

Thinness and neatness are most essential points to observe in making gauntlets and revers.

The collar of the bolero in *d*, and the cuff in *b* of the same diagram, are but variations of this drafting, which the student should be able to manage, as well as all other shapes, whilst the making will follow the directions already given.

Lapping. We shall now consider a method of finishing seams which is known as "lapping," which, if well done, looks very smart and effective.

If the lapped seams are to have only one row of stitching on the right side—which is quite sufficient for a short jacket—½ in. must be left over and above the thread-marks. If two rows are required, from ¾ to ⅞ in. will be necessary.

Baste the seams together, holding the work over the knee; stitch and press, as in previous lessons. It is important that the part left for the lap above and below the waist should be stretched. Cut the turnings away to within ¼ in. of the stitching on the right-hand side of A, B, and C, and on the left of D and E [75].

Turn the garment over, right side uppermost; baste the centre back seam, working the edge slightly over the seam with finger and thumb; then baste again the width of lap.

Each seam must be basted in the same way, the left side as at F and G, the right side as at H, I, and J—*i.e.*, with the seams facing towards the fronts. Fig. 76 shows the seams basted ready for stitching. The shoulders must also be treated in the same manner. It should be remembered that the stitching must be done very evenly if it is to be a success.

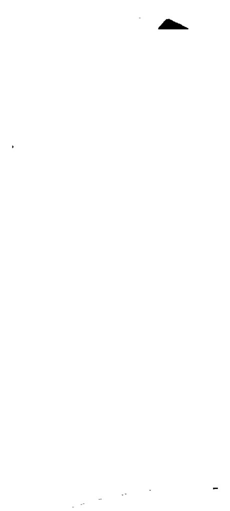
After the seams have been stitched, remove the basting and well press on the wrong side, as the success of the lapping depends largely on the pressing.

An important item to deal with is the sleeve-head. We have to be very careful at this point, so that the continuous run, or course, of the armhole shall, when the garment is finished, be unimpaired. The shoulder seams must lap towards the back.

Another effective way of finishing the seams is to stitch them on either side ⅛ in. from the seam after, of course, they are opened and pressed.

If the cloth is thick and of a firm, close make, such as box-cloth, the seams are usually lapped raw-edged. In this case, the preliminary stitching together of the seams is omitted, the edges being placed one over the other and stitched together at each edge of the outline.

This method, however, requires the greatest care and accuracy in cutting and measuring, the former being done with large and very sharp scissors. As a wrong snip may totally ruin the garment, a coat with such lapped seams should not be attempted till the learner has shown herself capable of making a perfectly-fitting one with plain seams.



77. STRAPPING TACKED IN PLACE

Strapping. A very pretty way of trimming a dress is to strap the seams. The straps are made in this way. They should be cut quite evenly, as wide again as they are to be when finished. The edges must be serged together lightly, holding the strap over the knee, and supporting it with the finger and thumb of the left hand. It is important to do this as directed, as, if the cotton is pulled tight, the mark of the serging will show all down the strap.

When the edges are finished, the strapping must be pressed flat with the serging in the centre. Now baste the strapping with the centre to the seam, holding the garment over the knee while so doing. This will keep the strapping long and prevent it contracting [77]. Stitch both sides of the strap ¼ in. from the edge, and baste in position, then secure it to the dress on the wrong side.

Strappings from ⅜ to ½ in. wide when finished make a very nice trimming for skirts, particularly if they are put on to form a design. For a dress, they are generally made from 1½ to 2 in. in width, and sometimes look well if piped with a contrasting colour. They can be made broader still for the fronts of a jacket, and have several rows of stitching, or may be varied in many ways.

CLASSIFICATION OF BIRDS

Flying, Running, and Extinct Toothed Birds, Grouped into Their Orders. Song Birds, Pigeons, Gulls, Game Birds, Eagles and Aquatic Birds

By Professor J. R. AINSWORTH DAVIS

BIRDS are vertebrates with hot blood (103° F., while mammals are 98° F.), and by the possession of feathers, and the alteration of their fore-limbs into wings, are clearly marked off from all other animals which now exist, though they resemble reptiles in many ways, and are undoubtedly derived from the same ancestral stock. The digits of the hand have been reduced to three, by loss of the fourth and little fingers, and there are never more than four toes in the foot, the little toe being always absent. No existing bird possesses teeth, though these were present in some very ancient extinct forms.

There are some 10,000 living species (as against under 3,000 mammals), which fall into two subclasses—flying birds (*Carinatæ*) and running birds (*Ratitæ*).

Flying Birds. The flying birds include the vast majority of forms, and it is a difficult task to subdivide them into smaller groups, for the differences between them are often comparatively trivial, and it is impossible to draw the sharp boundary lines which we have seen to exist in mammals. The older naturalists relied solely upon structure as obviously related to habits, and spoke of swimming, climbing, wading, scratching, perching birds, etc.; but this method of classification is now considerably modified, for it brings together some species which only resemble one another in a very superficial way, and separates others that are nearly related. There is a very large number of families grouped into orders, and it will here only be possible to give a very brief review of some of the more important of them.

Order 1. Perching Birds

(*Passeres*)

The large order of perching birds, which is admittedly the highest, includes more than half (some 5,500) of the known species, and the bulk of British "small birds" are referred to it. The four-toed foot is adapted to perching—*i.e.*, firmly grasping boughs and the like, in accordance with which the backwardly-directed great toe bears a comparatively large claw and possesses unusual powers of free movement. This type of foot may be conveniently studied in a tame canary. The young are helpless, almost naked, nestlings, which require assiduous care on the part of their parents.

The "song birds" (*Oscines*), with some of their close allies not specially remarkable for vocal powers, head the long list of perchers. It is interesting to note that the "song box" (*syrinx*), which is the source of melody, does not correspond to the "voice box" (*larynx*) of mammals, for it is situated at the place where the windpipe forks into a branch for each lung, while the latter is the modified top of the same.

Finches and buntings (*Fringillidæ*) are small birds with a strong conical beak, well able to deal with seeds or with a mixed diet. The following are familiar British forms: Goldfinch (*Carduelis elegans*) [270], chaffinch (*Fringilla cœlebs*), bullfinch (*Pyrrhula europæa*), linnet (*Linota cannabina*), yellowhammer (*Emberiza citronella*), and house sparrow (*Passer domesticus*). In the less common crossbill (*Loxia curvirostra*) the upper and lower halves of the beak cross each other in scissor-like fashion, an arrangement which facilitates the extraction of seeds from the cones of pine, fir, larch, etc. The wild canary (*Serinus canarius*), native to Madeira, the Azores, and the Canary Islands, is of comparatively sober plumage, and very unlike the numerous breeds which have been produced by domestication and artificial selection.

The American starlings (*Icteridæ*) possess longer and narrower beaks than the finches, and are interesting because they include the cow-birds (*Molobrus*), some of which, like cuckoos, deposit their eggs in the nests of more industrious songsters. One South American species (*M. rufaxillaris*) takes advantage in this way of an allied species (*M. badius*), which constructs a nest in the orthodox fashion.

Weaver birds (*Ploceidæ*), most of which are African, though the family ranges east to Australia, are remarkable for the way in which they weave stalks and fibres into rounded nests with tubular entrances. The most familiar form seen in captivity is the Java sparrow (*Munia oryzivora*).

The creepers (*Certhiidæ*) are represented in this country by the active little tree-creeper (*Certhia familiaris*), which may often be seen making its way up mossy walls and tree trunks, searching for insect-food with its slender curved beak, and using its stiff tail feathers as a means of support.

The beautiful little sun-birds (*Nectariniidæ*), which range through the hotter parts of the Old World, are often mistaken for humming birds, owing to their brilliant metallic plumage and long, slender beaks. They render valuable service to many plants by transferring pollen from flower to flower.

The starlings (*Sturnidæ*) are chiefly to be found in Africa and India, but are represented in most parts of the Old World, and the common starling (*Sturnus vulgaris*) is familiar in this country. It is even to be seen so far north as Greenland. The long, pointed beak deals with animal food, but some species also eat fruit and seeds. In Africa, the ox-pecker (*Buphaga*) devotes its attention to the ticks which infest cattle and other mammals.

The stout-billed crows and allied forms (*Corvidæ*) are represented in almost all parts of the globe, and their food is of miscellaneous character. The best-known British species are the raven (*Corvus corax*), carrion crow (*C. corone*), rook (*C. frugilegus*), jackdaw (*C. monedula*), magpie (*Pica rustica*), and jay (*Garrulus glandarius*).

The birds of paradise (*Paradiseidæ*) of the Australian region, despite their beautiful plumage [271] are closely related to the crows. Grouped with them are the more sober-plumaged bower birds, some of which are famous for the way in which they construct "bowers" for purposes of play, or even a "garden," which is made gay with flowers and berries, renewed as soon as they fade.

The pretty little insectivorous tits (*Paridæ*) are almost cosmopolitan, and haunt trees in search of their food. The blue tit (*Parus cæruleus*) [273] is, perhaps, the prettiest of our native species. The bearded tit or reedling (*Panurus biarmicus*) is now placed in a family of its own (*Panuridæ*).

Nut-hatches (*Sittidæ*), represented in Britain by the common nut-hatch (*Sitta cæsia*), resemble tits in habit, but are of somewhat larger size.

Shrikes (*Laniidæ*) have strong bills, often strongly hooked in relation to their carnivorous diet. Our commonest species is the red-backed shrike or "butcher bird" (*Lanius collurio*). The latter name has reference to the curious practice of impaling all sorts of small creatures in the neighbourhood of the nest, to serve as a "larder."

Swallows and martins (*Hirundinidæ*) are to be found practically all over the world, and furnish the most obvious British example of migratory species. Their marked powers of rapid flight, enabling them to catch insects on the wing, are associated with long, pointed wings, and a well-developed tail, often deeply forked. The short, broad beak can be opened very widely to receive the insect victims. The feet are small and feeble. There are three British species, the swallow (*Hirundo rustica*), with reddish throat and deeply-forked greenish tail, the white-throated martin (*Chelidon urbica*), and the sand-martin (*Cotile riparia*) which nests in sandbanks.

The wrens (*Troglodytidæ*), though very widely distributed, are most characteristic of the hotter parts of America. Our little native wren (*Troglodytes parvulus*), with its short, upturned tail, is often to be seen in hedges, using its slender pointed bill for the capture of insects and other small creatures, when these are to be had. In winter it largely feeds on fruits and seeds. A slightly larger kind of wren is limited to the island of St. Kilda, and regarded by some as a distinct species (*T. hirtensis*).

The water-ousels (*Cinclidæ*), which look something like stoutly-built wrens, frequent rapid upland streams, in which they dive for insects and small molluscs. Our native dipper (*Cinclus aquaticus*) belongs to the family.

The thrushes, warblers, and mocking-birds (*Turdidæ*) make up a cosmopolitan family, including many familiar forms, some of which are noted songsters. Among British species are the following: Song-thrush (*Turdus musicus*), blackbird (*T. merula*), wheat-ear (*Saxicola œnanthe*), robin (*Erithacus rubecula*), nightingale (*Daulias luscinia*), garden warbler (*Sylvia hortensis*), golden-crested wren (*Regulus cristatus*), our smallest native bird, and hedge-sparrow (*Accentor modularis*). The mocking-birds are American forms.

Wagtails and pipits (*Motacillidæ*) are among our best-known small birds. The former are typically Old World forms, distinguished by the jerky way in which they move their long tails up and down. Our commonest species is the water-wagtail (*Motacilla lugubris*), but the yellow wagtail (*M. raii*) is locally abundant. The shorter-tailed pipits are practically cosmopolitan, and are represented in Britain by a number of species, of which the meadow pipit (*Anthus pratensis*) is typical.

Larks (*Alaudidæ*) are mostly Old World forms, generally distinguished by the long straight claw of the great toe. The only species which nest in this country are the skylark (*Alauda arvensis*) and woodlark (*Lullula arborea*).

There are many other families of perchers, arranged in three groups, but as none are represented in Britain mention of them will be omitted here, though allusion may be made to some of them in the sequel.

Order 2. Woodpecker-like Birds

(*Picariæ*)

Here are included a large number of short-legged birds, which mostly dwell in trees, and commonly make their nests in holes. As in perchers, the young are helpless nestlings.

Woodpeckers (*Picidæ*) [264], as represented by the most typical members of the family, possess climbing-feet, in which the fourth as well as the first toe is directed backward. The stiff tail-feathers also serve as a support. The powerful beak is well suited for breaking open rotten wood in search of insects and their larvæ, while the wormlike tongue is capable of an extraordinary degree of protrusion. Covered with glutinous saliva, it easily secures the prey, aided by its hard barbed tip. The commonest British species is the green woodpecker (*Gecinus viridis*).

The brilliantly coloured toucans (*Rhamphastidæ*) of South America are distinguished by the possession of an enormous beak, greatly flattened from side to side. In the wild state they are supposed to live chiefly on fruits and seeds.

Barbets and honey-guides (*Capitonidæ*). The former are somewhat clumsy birds of bright plumage, well represented in the tropics, but the chief interest of the family is centred in the honey-guides native to Africa, the Himalayas, the Malay peninsula, and Borneo. Some of the African species are asserted, on good authority, to lead the way to bees' nests, their share of the plunder being apparently the grubs in the combs.

Passing over the brilliantly coloured trogons (*Trogonidæ*) of tropical regions and the actively climbing little mouse-birds, or colies (*Coliidæ*), of South Africa, we come to the American family of humming birds (*Trochilidæ*) [266], which, though mostly found in the tropical parts of the New World, range from Tierra del Fuego to Sitka. Their wonderfully coloured metallic plumage almost defies description, and their wings can be moved up and down so rapidly as to be almost invisible, producing at the same time the humming sound from which the popular name has been derived. Like the African sun-birds, they render service to a number of bright-blossomed plants by transferring pollen.

The swifts (*Cypselidæ*), represented in Britain by one species only (*Cypselus apus*), if rare stragglers are ignored, closely resemble swallows in appearance and habits, but differ from them in many constructional features.

The goatsuckers, or nightjars (*Caprimulgidæ*), share with bats the work of hawking for insects after sunset. Some species, however, feed during the day. Our harmless nightjar (*Caprimulgus europæus*), though much maligned, is a most useful bird, which wages war on many insect pests. It is greatly aided in this pursuit by an unusually wide mouth, fringed with bristles. A well-known foreign species is the whip-poor-will (*Antrostomus vociferus*) of America, while the more-pork bird (*Podargus cuvieri*) of Tasmania belongs to a closely related family.

The best known members of the hoopoe family (*Upupidæ*) are distinguished by the possession of a beautiful crest on the head, well seen in the common species *Upupa epops* [268], which ranges from Britain (where it is an occasional visitor) to Japan.

The hornbills (*Bucerotidæ*) of Africa, India, and the Australian region are remarkable for their enormous beaks, upon the upper side of which is often a large projection known as a "casque" or helmet.

The bee-eaters (*Meropidæ*) are brilliantly coloured birds, with slender, curved beaks, found in most parts of the Old World. One species (*Merops apiaster*) occasionally wanders to our southern shores. The same bird is well-known and dreaded by bee-masters in Spain.

Kingfishers (*Alcedinidæ*) are nearly all natives of the Old World, possessing long, powerful beaks, and, for the most part, brilliant plumage. The third and fourth toes of their comparatively feeble feet are largely united together. This peculiarity probably assists our native species (*Alcedo ispida*) [267] to maintain its hold easily on some branch near a stream while it patiently awaits the appearance of the fishes upon which it preys.

Cuckoos (*Cuculidæ*) are widely distributed through both hemispheres, but only the Old World species, and not all of those, trade on the parental affection of other birds. The feet resemble those of woodpeckers. Our native cuckoo (*Cuculus canorus*) is not unlike a hawk in appearance, and the familiar love-call, which is uttered by the male bird only, is not a general characteristic of the family.

Order 3. Owls

(*Striges*)

There is only one family (*Strigidæ*), including familiar nocturnal birds of prey, with soft plumage, large eyes, and hooked beaks. Their general appearance is too well known to need detailed description, but it may be mentioned that the fourth toe can be turned either forwards or backwards at will. The young are helpless. Owls are found all over the world, and the most notable British species is, perhaps, the barn-owl (*Strix flammea*).

Order 4. Parrots

(*Psittaci*)

Here, again, we have but a single family (*Psittacidæ*), with some members of which everyone is acquainted. Climbing feet are present, with well-curved claws, but the most remarkable feature is the prominent hooked beak, the upper part of which is movable, being united by a hinge-joint to the skull. This increases its efficiency for both feeding and climbing purposes. The young are naked and helpless.

Parrots are most strongly represented in the Australian region and South-east Asia, after which comes South America. Africa and South Asia are pretty well off in the number of species, but only one is to be found in North America.

The curious nocturnal kakapo, or ground parrot, of New Zealand (*Stringops*), has almost lost the power of flight, and radiating feathers round the eyes give it an owl-like appearance. The pretty little grass-parakeets, or budgerigars (*Melopsittacus*), are natives of Australia, while the name "love-bird" is given to some small African (*Agapornis*) and South American (*Psittacula*) forms. Well known are the African grey parrot (*Psittacus erithacus*), notable for its imitative powers, and the gaudy American macaws (*Ara*, etc.) [265]. The crested cockatoos (*Cacatuinæ*) are only to be found in the Australian region, and north from this to the Philippine Islands.

Order 5. Pigeons

(*Columbæ*)

These are plumply built birds, with nostrils situated within a bare patch of swollen skin (*cere*) at the base of the beak, which is well developed, and mostly suited to vegetable food, for the temporary accommodation of which the gullet is swollen into a large crop. Only the first toe is turned back, and the feet are suited both for perching on trees, which are the usual home, and progression on the ground. The young are naked and helpless.

Pigeons and doves (*Columbidæ*) are very widely distributed, and of the four British species the rock-dove (*Columba livia*) is most interesting, as representing the ancestral stock from which all the domesticated breeds of pigeon have arisen by artificial selection. The large crowned pigeon (*Goura coronata*) and allied species, native to New Guinea and the adjacent islands, are perhaps the most striking forms.

A related family (*Dididæ*) includes three clumsy, flightless forms, all of them extinct—*i.e.*, the dodo (*Didus ineptus*) of Mauritius, a related species (*D. borbonicus*) in Bourbon, and the solitaire (*Pezophaps solitarius*), formerly a native of Rodriguez.

Order 6. Gulls and Auks

(*Lariformes*)

The gulls (*Laridæ*) are very widely distributed sea-birds, of which the staple diet consists of fish and other marine animals, though at times they may migrate inland for feeding purposes, as well as for breeding. The feet are webbed, and the great toe is small. The young are fairly helpless. Our commonest native species are the common gull (*Larus canus*), the herring-gull (*L. argentatus*), and the black-headed gull (*L. ridibundus*). The terns, or sea-swallows, are related forms, with pointed tails and wings, and the common tern (*Sterna fluviatilis*) is abundant on the British coasts.

The chief British representatives of the auks (*Alcidæ*), which resemble gulls in structure and habits, are the razorbill, the guillemot, and the curious puffin or sea-parrot (*Fratercula arctica*). The flightless great auk or gare fowl (*Alca impennis*) formerly abounded in the neighbourhood of Iceland and Newfoundland, but has been extinct since 1844.

Order 7. Plovers

(*Limicolæ*)

The birds of this order are cosmopolitan, and are distinguished by the slender, often elongated, beak, while many of them are long-legged waders. The feet are not webbed. The young are covered with down when hatched, and soon learn to look after themselves.

Of well-known British species belonging to the chief family (*Charadridæ*) the following may be mentioned: Golden plover (*Charadrius pluvialis*), ringed plover (*Ægialitis hiaticula*), curlew (*Numenius arquata*), lapwing or peewit (*Vanellus cristatus*), common sandpiper (*Totanus hypoleucus*), woodcock (*Scolopax rusticola*), and common snipe (*Gallinago cœlestis*).

Order 8. Rails

(*Grallæ*)

These are somewhat primitive forms, in which the laterally flattened body facilitates progress through grass and thick undergrowth. Many of them have lost the power of flight. The young are covered with down when hatched and able to run about at once.

The best known British species included in the single family (*Rallidæ*) is the landrail, or corncrake (*Crex pratensis*), while of aquatic forms we have the water-rail (*Rallus aquaticus*), moorhen (*Gallinula chloropus*), and coot (*Fulica atra*).

Order 9. Bustards and Cranes

(*Alectorides*)

These are long-legged birds, the young of which are well developed when hatched, as in the last order.

Bustards (*Otididæ*) are Old World forms which mostly live on plains. The great bustard (*Otis tarda*) was once a native of Britain.

The graceful cranes (*Gruidæ*) are widely distributed waders, of which one species, the common crane (*Grus communis*), was a native of East England till the end of the sixteenth century, but is now only a rare visitor.

Order 10. Game Birds

(*Gallinæ*)

The members of this order are ground birds, with strong, blunt-clawed feet adapted for scratching up the ground in search of food. Their young are soon able to take care of themselves.

McClellan

274. AFRICAN OSTRICH

Apart from the mound builders (*Megapodiidæ*), the curious nesting habits of which will be elsewhere mentioned, the only family requiring notice is that including pheasants and their allies (*Phasianidæ*), some of which are to be found native in most parts of the world. Several familiar domesticated birds belong here—*e.g.*, guinea-fowl, which have been derived from a West African species (*Numida meleagris*); and turkeys originate from a North American form (*Meleagris gallopavo*). The red jungle-fowl (*Gallus bankiva*) of South Asia are ancestral to domesticated fowls, and the peacock (*Pavo cristatus*) [269] was originally native to the same part of the world.

The following game birds and ornamental forms also belong to the pheasant family: Argus pheasant (*Argusianus argus*), golden pheasant (*Chrysolophus pictus*) [272], common pheasant (*Phasianus colchicus*), common quail (*Coturnix communis*), partridge (*Perdix cinerea*), capercailzie (*Tetrao urogallus*), black grouse (*Lyrurus tetrix*), red grouse (*Lagopus scoticus*)—the only undoubted species of bird restricted to Britain—and the ptarmigan (*Lagopus mutus*).

Order 11. Eagles and Vultures

(*Falconiformes*)

The predaceous character of the members of this order is clearly indicated by the strong hooked beak, and the powerful talons. The great toe cannot be turned forwards at will as in owls. The young are helpless, and remain for an exceptionally long time in the nest. Members of this order are to be found all over the world.

As a type of the larger members of the falcon family (*Falconidæ*) the golden eagle (*Aquila chrysaëtus*) may be taken. This handsome bird, or some allied species, served as the emblem of Rome in older times, and contributes largely to the heraldry of modern Europe. It breeds in Scotland (here and there in Ireland also), and has a very wide range in the northern hemisphere. A number of smaller species belonging to the family are also British, and of these the kestrel, or wind-hover (*Falco tinnunculus*), and sparrow-hawk (*Accipiter nisus*) are familiar.

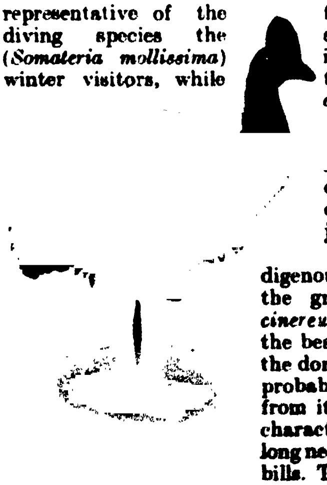
The bare-necked carrion-feeding vultures are divided into two families, of which one (*Cathartidæ*) includes the American forms, and the other (*Vulturidæ*) the Old World species. The gigantic condor (*Sarcorhampus gryphus*) of the Andes, with its 9-ft. spread of wing, is surpassed in size by no other existing flying bird, while the little Egyptian vulture (*Neophron percnopterus*) is one of the smallest members of the group.

Order 12. Ducks, Geese, and Flamingoes

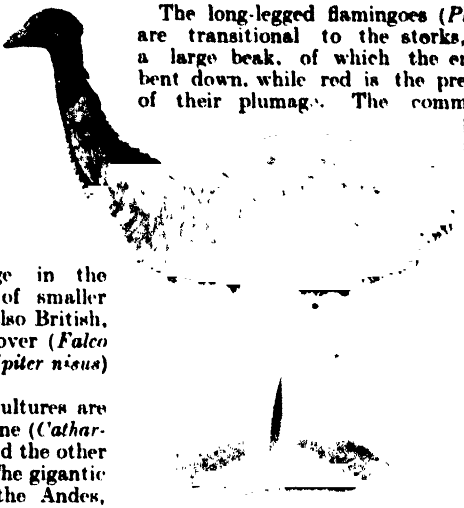
(*Anseres*)

The species of this large and cosmopolitan order are web-footed, aquatic birds, mostly possessing a flattened bill. The young are able to run from the nest as soon as hatched.

One extensive family (*Anatidæ*) includes ducks, geese, and swans. Our wild duck (*Anas boscha*), ancestral to the domestic form, is a typical representative of the first group. Of diving species the eider duck (*Somateria mollissima*) is one of our winter visitors, while teal (*Querquedula quet'a*) widgeon ([illegible]a pene[illegible]), both non-divers, are common objects of sport.



Of geese indigenous to Britain, the grey lag (*Anser cinereus*) is perhaps the best known, and the domestic form is probably descended from it. Swans are characterised by their long necks and shorter bills. The white swan (*Cygnus olor*) is common throughout Europe, and also ranges into Asia and North Africa. The black swan (*C. atratus*) of Australia and the black-necked swan (*C. nigricollis*) of South America are remarkable on account of their colour.



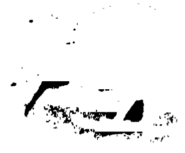
276. EMEU

The long-legged flamingoes (*Phœnicopteridæ*) are transitional to the storks, and possess a large beak, of which the end is sharply bent down, while red is the prevailing colour of their plumage. The common flamingo (*Phœnicopterus roseus*), widely distributed through Europe, Asia, and Africa, is rose-coloured.

Order 13. Herons and Storks

(*Herodiones*)

The long-legged waders which make up this order are represented in all parts of the world. The beak is long, strong, and pointed, and the feet are never more than partially webbed. The young are helpless.



277. KIWI

Herons (*Ardeidæ*) are chiefly represented in Britain by the grey heron (*Ardea cinerea*), to which the bittern (*Botaurus stellaris*), now only an irregular visitor, is allied.

Of storks (*Ciconiidæ*), the common white species (*Ciconia alba*), occasionally seen in the east of England in spring, is sufficiently abundant in Europe, from which it migrates in late summer to Africa. The bald-headed adjutants or Marabout storks, with huge beaks, are among the most amusing inhabitants of the Zoological Gardens. They are indigenous to Africa and India, and the bareness of the head is an adaptation to the carrion-feeding habit.

Order 14. Pelicans and Cormorants

(*Steganopodes*)

This order embraces short-legged aquatic forms, which chiefly feed upon fish. All four toes are connected by webs. The young are helpless.

The pelicans (*Pelicanidæ*) are comical-looking birds with a very large beak, on the under side of which is a large pouch for the temporary reception of food. The common white pelican (*Pelecanus onocrotalus*) is native to South-east Europe and parts of Africa.

Cormorants (*Phalacrocoracidæ*) are among the most industrious fishermen of the sea-coast. We have two native species, the large black cormorant (*Phalacrocorax carbo*), and the small green cormorant or shag (*P. graculus*).

The gannets (*Sulidæ*) are represented in Britain by the common gannet or solan goose (*Sula bassana*), of which a noted breeding place is the Bass Rock in the Firth of Forth.

Order 15. Petrels and Albatrosses

(Tubinares)

The strong, somewhat hooked beak of the birds included in this order is well adapted for fish-eating, the feet are webbed, but the great toe is reduced or absent. The nostrils are placed at the ends of short tubes. Many of the species frequent the open sea. The young are helpless.

There is but one family (*Procellariidæ*), of which the following members may be noticed: The storm petrel (*Procellaria pelagica*), known to sailors by the name of "Mother Carey's chicken," and the object of much superstition, and the wandering albatross (*Diomedea exulans*) with an enormous spread of wing

Order 16. Divers and Grebes

(Pygopodes)

This is another group of thoroughly aquatic birds, well adapted to the pursuit of fish. The strong sharp beak is flattened from side to side, the legs are set on very far back, and the feet are much as in the last order, except that in the grebes they are not webbed, but the toes are fringed with flaps of skin. The young are helpless.

Our commonest native species of the sharp-beaked divers (*Colymbidæ*) are the great northern diver (*Colymbus glacialis*) and the red-throated diver (*C. septentrionalis*).

Two of the grebes (*Podicipedidæ*) haunt our inland waters, the great crested grebe (*Podicipes cristatus*), and the little grebe or dabchick (*P. fluviatilis*).

Order 17. Penguins

(Impennes)

These curious inhabitants of the southern hemisphere are all placed in one family (*Spheniscidæ*), of which the members are better adapted to an aquatic life than any other birds. The wings are useless for purposes of flight, but are converted into efficient paddles. All the toes are connected by webs except the small first one, and the legs are set on exceedingly far back, which renders the gait on land extremely peculiar. The sharp beak is straight, and the young are helpless when hatched out.

Toothed Birds. A small order of extinct birds is represented by toothed forms (*Ichthyornis*), of no great size, which lived during the chalk period in the western hemisphere, and probably resembled gulls in their habits. The members of another extinct order belonging to the same period also possessed teeth, and some of them (*Hesperornis*) were three feet or more in height. They were flightless birds, presenting marked resemblances to the divers, but were, perhaps, still more closely allied to the running birds, which we must now proceed to consider.

Running Birds. The running birds, characteristic of the southern hemisphere, have lost the power of flight, in accordance with which the breast-bone has no projecting keel. They have specialised for swift progression on the land, and the feathers are loose in texture. The young are able to run about as soon as hatched.

One family (*Struthionidæ*) includes only the African ostrich (*Struthio camelus*), the largest existing bird, being as much as 8ft. high [274]. Only the third and fourth toes are present, the former being much the larger. Both are padded below, like the extremities of camels, and for the same reason.

South American ostriches (*Rheidæ*) are smaller forms, possessing three toes. The same number of digits are present in the cassowaries (*Casuariidæ*) [275] of North Australia, New Guinea, and the adjacent islands. The black plumage is hair-like, and the neck is more or less bare, and generally wattled, these parts being brightly coloured. There is a bony outgrowth, or "helmet," on the top of the head.

The three-toed emeus (*Dromæidæ*) [276] are not unlike cassowaries, though somewhat larger, but possess neither the brightly coloured bare patches and outgrowths in the neck region, nor the "helmet" of the latter. The beak is flattened from above downwards.

The kiwi (*Apteryx*) [277] of New Zealand represents still another family (*Apterygidæ*), and is the only living running bird possessing all four toes. It is about the size of a large fowl, and its long narrow beak is used in probing the ground for earthworms. In many points of structure—*e.g.*, the number of toes—the kiwi resembles the moas (*Dinornithidæ*) of New Zealand, all of which have been extinct for three hundred years or more. The largest of these (*Dinornis maximus*) stood about 12 ft. high, while the smallest (*Anomalopteryx parva*) was no larger than a turkey.

Record Eggs. Until some two hundred years ago, huge four-toed running birds (*Æpyornithidæ*) existed in Madagascar, the largest of which was about 7 feet high. These were probably the original of the fabulous "roc," spoken of long since by Marco Polo in recounting his eastern travels, and often mentioned in the "Arabian Nights." They surpass all other known birds in the size of their eggs, some of which measure no less than 13 in. long by 9½ in. broad, with a capacity of about two gallons.

The oldest kind of extinct bird (*Archæopteryx*) is represented by two species about the size of a rook, which lived in what is now the European area, about the middle of the secondary epoch [see GEOLOGY]. The structure is in many ways less specialised than that of existing forms, and affinity with reptiles is indicated not only by the presence of teeth, but also by the possession of a long lizard-like tail which, however, supported about 20 pairs of quill feathers.

SHOPKEEPING

16

Continued from page 2086

DAIRYMEN

Since the days when milk was produced in dirty town cowsheds, carried in open pails on a pair of yokes by buxom, short-skirted women and gaitered men, and delivered in a generally impure condition, there have been great changes. Our knowledge of the influence of germ-life on a very perishable fluid has enabled us to take precautions to ensure purity and cleanliness and to save losses of life and money which were in those days deemed impossible.

Precautions for Purity. The milk now consumed by our large populations is produced almost entirely in the country, while every farm, if not actually inspected, is required by law to be under systematic inspection. Milk must be pure, clean, cooled by refrigeration to a low temperature, and contain at least three per cent. of fat, while persons suffering from any form of contagious or infectious disease must not handle it, the cows which produce it, or the utensils in which it is carried. These precautions demand considerable knowledge on the part of the milk vendor. Notwithstanding the law, however, adulteration is still common, skimmed or separated milk—*i.e.*, milk from which the cream has been removed by hand or by machine—being employed for the purpose instead of water, while pure milk is often badly cooled, badly strained, and delivered in so dirty and imperfect a condition that a sediment often appears at the bottom of a vessel into which it is poured. The result is that epidemics of disease occasionally occur, that the germs of tuberculosis, or consumption, are frequently discovered by scientific examination, and that large quantities of milk are spoiled during the hot weather.

The Milk Vending Business. Milk is sold by other traders than the dairyman, with the result that its quality and character are more frequently impaired. It is retailed by itinerant vendors, by the occupiers of chandlers' shops, by confectioners, fruiterers, and general dealers. We have, however, in these pages, to deal with the dairyman, whose business should be to obtain his supplies direct from the producer, or, it may be, as in the case of very small concerns, from large wholesale merchants.

A milk business is either purchased or established. To establish a new business is extremely difficult in a district which is already well supplied; but our population is growing, and in all large cities, as houses are built shops are opened, and the prospective dairyman obtains his chance. Similarly, in many small country towns badly supplied by small cowkeepers, there are openings for well conducted, attractive shops at the hands of men of energy, knowledge, and experience. In starting an entirely new business, the dairyman must take great pains to select his locality and to estimate with care the probable increase in the population, the existing competition, the cost of labour, rent, rates and taxes, the contiguity of the railway-station, and the class of customer to whom he would look for support. His aim should be not only to obtain clients who consume large quantities of milk but who are willing to pay the best price for it. This work involves considerable labour, enterprise, and patience, and he may, therefore, find that, after all, if his capital is sufficient, it would pay him better to purchase an existing and successful concern. To this end he should both advertise and reply to advertisements, and, in addition, make his requirements known to one of those agents who negotiate businesses of this character.

Scrutiny before Purchase. Having met with something which he believes may suit him, he will make the most careful investigation as to the quantity of milk and other produce sold, its prime cost, and what it realises by retail. He will examine the books, and take care to verify their accuracy; he will go the rounds with the milk deliverers, and ascertain precisely what is sold and how far he may trust the honesty and soundness of the customers. In many populous districts the people are constantly moving, and leaving their milk bills unpaid, but in justice to himself he will leave no stone unturned to satisfy himself before he pays a shilling for what might possibly be a more or less bogus concern. The milk trade offers many opportunities for fraud, and of this fact many avail themselves. The man, therefore, who will adulterate milk and cream, sell imported butter and eggs as fresh home produce, or infants' milk in sealed cans, drawn from special cows which he does not possess, is not likely to display any particular sense of honour in dealing with a proposed purchaser of his business.

The Shop. A dairyman's shop should be equipped with two objects, first, to attract customers by its generally smart and cleanly appearance, and, secondly, to minimise any possible influence upon the keeping qualities and flavour of the goods. As in the apartments in the back premises, the floors, walls, ceilings, counters, and fittings should be constructed of such materials as will reduce the collection of dirt to the smallest possible quantity. The floors should be tiled, the tiles non-absorbent and laid in cement; the counters marble, the shelving of marble or slate; the walls hard and smooth, either tiled or of parian cement; and the various fittings as far as possible of glazed earthenware.

To Prevent Contamination. The atmosphere, even of a town suburb, is crowded with an incalculable number of particles of dust and bacteria; hence, as far as possible, all perishable goods, and especially milk, cream, and butter, should be under cover. The milk in the vessel on the counter should never be exposed; nor should butter, as is common in almost all provision dealers' shops, be exhibited in large blocks just as it is turned from the cask or the case. Butter should be on sale in rolls, preferably marked with a special brand, already made up, and, except such as are reserved in a glass showcase, ready packed in grease-proof paper and dainty boxes. Window or counter ornaments and plants are attractive, and add to the general appearance of a well-arranged retail shop. Hints, however, may be obtained by examining some smartly equipped premises, such as those of Messrs. Welford and the Express Dairy Company, in London, Hailwood's in Manchester, and Frowde's in Brighton.

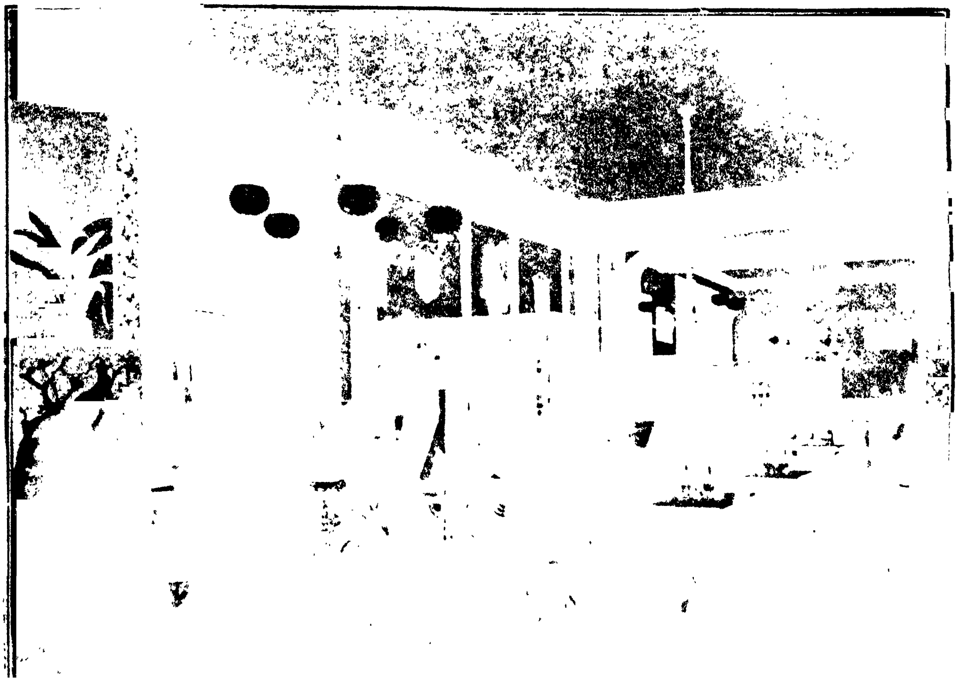
The Back Premises. The back premises, in which the milk and other produce are handled in bulk, should be as carefully equipped and as clean as the shop itself; and customers should be systematically invited to inspect them, for confidence is in this way easily imparted. There should be a milk-cooling tank, a milk refrigerator, a separator for removing the cream from unsold milk, a churn, a butter-worker, and other similar appliances necessary for converting this cream into butter; an apparatus for sterilising the various utensils and vessels employed, a cold room or safe for cream and butter—indeed, for milk also, if the expense can be borne—a steam jet, and hot and cold water with hose for cleansing floors, churns, and other appliances. The premises should be carefully ventilated, and the drains carried outside, and carefully trapped. There should also be a well-paved covered outside shed for receiving and dispatching the milk in perambulators and carts—if these are used—and cleansing the larger portions of the plant.

Contracting for Milk Supply. Where the quantity daily sold warrants the practice, the milk should be purchased direct from the farmer under contract. Contracts in the milk trade usually provide for two prices, from April 1st to September 30th, and from October 1st to March 31st, or thereabouts. The buyer will stipulate to purchase on the London system—per barn gallon of 17 pints, by the imperial gallon, or by the dozen quarts, as the case may be. He should require the milk to contain at least 3·4 per cent. of fat, sampling it regularly and obtaining periodical analyses. So long as it covers the standard, he will not be too exacting with the vendor if its average is satisfactory. While, however, not always insisting on these figures, he should look for at least 3·5 per cent. of fat, which every farmer can supply if he chooses to take the trouble to select his cattle. The following is a sample form of agreement used by one of the largest and best London retailers:

> AGREEMENT made this between (hereinafter called the vendor), of the one part, and (hereinafter called the purchasers), of the other part.
>
> For the considerations herein expressed, it is mutually agreed between the parties thereto as follows—namely:
>
> The vendor agrees to sell, and the purchasers agree to buy, from to pure, sweet, and merchantable cows' milk in quantities of to lots daily in the months between Lady Day and Michaelmas, and to lots daily in the months between Michaelmas and Lady Day.
>
> Each lot to consist of imperial pints, and the price per lot to be
>
> The vendor to pay all railway charges, and deliver the milk free to the purchasers at the railway station of the Railway twice daily at o'clock in the morning, and at o'clock in the evening. The account of the milk delivered to each Saturday night to be forwarded to the purchasers not later than the following Tuesday morning.
>
> The vendor further agrees with the purchasers that he will in all respects conform to all the conditions and stipulations mentioned in the Schedule hereto, and abide thereby in every respect, and such conditions and stipulations shall form part of this agreement.

The schedule deals with the quality and purity of the milk, cooling, straining, cleaning vessels, condition of cows, sickness, churns and cans, inspection, and other necessary details.

Relations with the Farmer. It is important to see that the daily supplies of milk arrive from the producer in clean cans or churns. If either be unclean, or if the milk be coloured, mixed with preservative drugs, or tainted, it should be returned at once, and an explanatory telegram sent. The farmer should not be beaten down in price; he must be paid well for a first-class article—feeding, cooling, straining, and cleaning all involving extra labour. The milk should be paid for with unerring regularity—farmers generally prefer weekly payments—and it should be delivered punctually to customers. The carriers should be supplied with measured quantities of milk for their rounds, and never expected to deliver more than they take. Samples should be taken from each deliverer's churn before it is locked. In no case should they be allowed to deliver milk except from the taps of their churns. The milk carrier should be paid well, and receive extra payment for every new customer he obtains. He should be required to give good measure. It may be found that in some instances short measure is given, and that in consequence milk is sold for cash which is not accounted for.



AN ARTISTIC INTERIOR: ONE OF MESSRS. WELFORD'S DAIRY SHOPS

Cream and Chemicals. Customers should be supplied with cards explaining the conditions necessary for keeping milk and cream sweet, and the food value of each article. The sale of cream should be fostered with energy; it may be sold with profit at two-thirds its present retail price, and a reduction on this basis might be expected to largely increase the demand. The cream trade will bear great expansion. Chemicals or drugs should never be employed to preserve either milk or cream; customers are learning to regard both with suspicion, and many leave vendors who use them. Although it is not a common practice in the trade, the retailer who would conduct a high-class business will be well advised to stick to British and Irish butter [see Buttermen in this course], to make a speciality of a well-selected English make for sale to the wealthy, and to brand every roll. A business man supplying well-to-do customers should avoid margarine.

Milk should never be coloured; although the practice is common, it is dishonourable. Rich milk producing plenty of thick, yellow cream should be the leading article; it will recommend itself and secure many customers. One of the oldest and most prominent firms in London find it possible to sell milk which is neither coloured nor preserved all the year round and yet the trade in general insist on both practices.

Precautions with Employees. If an employé or any member of his family is attacked with a contagious or infectious disease the employé should be kept off the employer's premises at the discretion of a medical man, and paid all or part of his wages; this should be a matter of agreement on engagement. Every employé should be required to report any case of illness in his home. Servants handling milk should wash before starting on a round for its delivery. Each man should be provided with a clean smock coat or jacket weekly, or more often if required. The milk vessels supplied to each carrier should be examined before he receives the milk for his round. The milk can or churn should be locked up before starting, the quantity of milk supplied being recorded as well as that remaining on return from the round. A veterinary inspector should be employed to make an occasional report as to the health of the cows and the conditions of the premises of the farmers supplying the milk. He should also be asked, where a medical man is not engaged for the purpose, to inquire and report upon the health of the families of the farmer and his employees.

Sterilised Milk. Customers should be encouraged to purchase bottled sterilised milk, which can be supplied at small expense. This milk may be delivered in weekly lots. Thus, instead of calling upon the customer twice daily, one weekly call becomes sufficient. If customers object, they may be induced to accept bottled milk for their Sunday supply, thus reducing Sunday labour, which is an objectionable feature of the dairyman's trade

The following is a sample form which should be filled up by farmers from whom it is proposed to purchase milk.

PROPOSAL TO SUPPLY MILK.

Name and address in full........................
Telegraph office and station........................
Time milk will arrive at station of destination.......
Number of cows kept in milk and if any tuberculous
....
Daily quantities for sale........................
To whom previously sent ?........................
Is your farm generally in a good sanitary condition ?
....
Has it been medically inspected, if so, by whom, and at what date ?........................
Source of water supply :
For domestic use........................
For cooling........................
For washing utensils........................
For cattle drinking........................
Is there any sickness of a contagious nature on your farm or in the neighbourhood ?..................
Price asked per imperial gallon delivered at our station ....

The milk retailer should carefully study the laws governing the supply of milk and other dairy produce. These include the Sale of Milk Regulations (1901), the Sale of Butter Regulations (1902), Sale of Food and Drugs Act (38 and 39 Vic. ch. 63), Sale of Food and Drugs Amendment Act (1875), Sale of Food and Drugs Act (1899), Margarine Act (1887), Dairies, Cowsheds, and Milkshops Order (1885).

DOMESTIC ENGINEERS

By a process of evolution there is growing up in our large towns a class of traders which has not yet been generally recognised by the public. For the want of a better name that of *domestic engineer* has been given to the class, but the term is something of a misnomer, because the word engineer presupposes one who designs or manufactures something of iron, steel, or metal. These tradesmen are not strictly retailers. They make small pretence to window displays and show-room stocks, though some lines, chiefly of the nature of materials, have to be carried. The business of this class of tradesmen is to erect and maintain in repair the various fittings which go to complete the equipment of modern houses. The trade is at present split up into a number of well-defined sections, but there are evidences that it will become concentrated under single management in the course of a few years. An up-to-date review of the many departments of shopkeeping generally would not be complete without some reference to the possible development of this business from the commercial standpoint, and elsewhere the SELF-EDUCATOR will deal with the technical sides of this opening for a career.

The Engineer in the House. When one looks round a house it is discovered that four distinct classes of mechanics besides the builders have had a hand in the work. These are the plumbers, the hot-water fitters, the electricians, and the gasfitters. To the first falls the cold-water service, certain parts of the roofing, the flashing round the sinks, the fixing of the bath, lavatory basins and closets. The hot-water supply is executed by the pipefitter—sometimes the plumber does this—who also fixes the range in conjunction with the builder's men. The electrician, or wireman, puts in the bells and the electric light, and, finally, if there be a gas cooker, gas fires, or incandescent gas lamps, the gasfitter takes a turn. At present these trades overlap more or less, and so far as the plumbers are concerned there is some anxiety to secure the lot exclusively—a game of grab to which the hot-water fitters do not feel inclined to agree; but from the contention—for there is contention—a new class of tradesmen, who will qualify themselves to undertake the whole of the work, will be evolved. These will employ plumbers, pipefitters, and wiremen, and by concentrating work under one management, expenses will be kept down, and efficiency secured.

Possible Developments. Under the conditions indicated, the business of domestic engineering ought to develop large possibilities. Fifteen years ago a £30 house with a bath and hot water supply was the exception. To-day houses in the London suburbs letting as low as £26 have to be so fitted. To-day not one house in a hundred in even good residential districts has its independent hot water warming installation. In fifteen years' time these will be the rule, and more than likely a small electric motor and electric cooking appliances will also be common.

Particularly are there splendid opportunities of developing the business in heating by hot water apparatus. Within the past few years the cost of radiators and boilers has been greatly reduced, and their efficiency improved. The public are gradually coming to recognise that coal fires are wasteful. The objection against the radiators on the score of appearance has been removed by artistic patterns and good moulding, and so much has been printed about smoke abatement and fog in the press of recent years that the silly sentiment about seeing a cheery fire no longer carries its former weight.

Equipment for the Work. The capital required to start in business as a domestic engineer would be about £350. Of this about £200 to £250 will be sunk in plant, which would include a small gas engine, or an electric motor of equivalent power, and a few small machine tools, such as a drilling machine, lathe, lawn mower, grinder, screwing machine, polishing wheel, lacquering table, besides the usual portable tools associated with the plumbing, gas-fitting, and electric wiring trades. The balance of the money would meet the working requirements of the business, including some stock, but obviously the material required for most of the contracts would require to be ordered as it is wanted, and consequently not a large sum would be invested in this direction. The prospects of success are considerable, and the technics of the business not particularly difficult to acquire, provided the tradesman has a practical knowledge of at least one of the departments.

On the whole, the plumber seems to have the best chance of making the business a success, not because he is ordinarily the best craftsman of his class, but on account of the standing given to the craft by the system of registration which obtains in the trade. It is a moot point whether registration affords the public the extra security against scamped work which is claimed by its advocates. The fact remains that the plumber, by common consent, seems to rank high among the other trades indicated in spite of gibe and jest in the popular papers. For one thing, he is usually a handy workman, able to use a variety of tools besides those peculiar to his own craft, although in these days of trades unions, he is not always willing to do so. Here, however, we are dealing not with the prejudiced trade unionist, but with the man who is anxious to drop the mechanic's overall for the more profitable garb of master man and employer of other men's labour.

The Necessary Technics. How can an aspirant for a wider sphere of operations qualify himself? We put the matter to the younger men, for they can use the opportunity to the best advantage. The first thing to do is to throw to the winds all the nonsense about poaching on other trades. No job must be refused if by trying it the mechanic can add to his experience. Besides, a certain amount of study will be necessary for the domestic engineer. His customers will expect him to have a fair amount of technical knowledge on such matters as sanitation, light, heat, ventilation and electricity. By a happy coincidence the men to whom we are addressing ourselves have in their hands much of the information that will assist them to proficiency, for the scheme of the SELF EDUCATOR covers all the subjects as well as such others as geometry, draughtsmanship, building construction, commercial arithmetic, and book-keeping. In a word, the man with a craft at his fingers' ends and enough brains in his head to understand the elements of science, stands a far better chance of succeeding in this business than another without these qualifications, although the latter might have a big bank balance to his credit.

Stock. It is hardly necessary to catalogue the stock that would be requred to be held by a tradesman in business as a domestic engineer. A section has already been devoted to builders' merchants, others are in preparation dealing with ironmongery and other branches of trade which cover the stock to be carried. Briefly, the stock must include such goods as gas tube and fittings, lead and lead pipe, compo pipe, some sanitary goods in salt glazed, cane, and white ware, electric wire and fittings, possibly a few bells and batteries, electric lamps, gas mantles, some glass such as shades and chimneys, etc. For the rest, the domestic engineer need only to know where to buy what he wants, and to have proper relations with his wholesale firms and manufacturers, who nowadays are expected to send orders from stock at very short notice.

The profits have yet to be determined, but in a given turnover it would be a safe estimate that half represented material sold, and the remainder labour charges. The former ought to average a profit of 20 per cent. gross on the cost price, the latter probably rather less; but much would depend upon the locality in which operations were carried on. Business among builders, for example, would be cut finer than work done for substantial householders. The whole matter is in a somewhat nebulous stage at present, the work being spread over many trades; but sooner or later it will be systematised, and those that are ready with a theoretical knowledge of the trades different from the one they practise will be the men to catch the plums which are nearly ready to fall.

DRAPERS

The Evolution of the Draper. In the ages that are past the draper was a man who sold cloth; to-day he is a merchant who deals in a heterogeneous assortment of goods, with drapery as an unobtrusive side line. For drapery, properly so-called, means cloth and stuff goods, household and personal linen, white cotton piece-goods (or "longcloths"), cottons and calicoes, Irish linen, tablecloths, serviettes, blankets, towelling, prints, flannel, etc. All these things, of course, are necessaries of the trade of a draper still, but the present-day retailer finds that there are many other lucrative adjuncts to his business—more profitable and easier to handle and to stock—that the present generation of purchasers demands. It can be easily understood that, as this country grew richer and more "civilised," the desire for finery increased, and nowadays millinery (with flowery and feathery trimmings), stoles, hosiery, gloves, ribbons, laces, ladies' outfitting, corsets, blouses, mantles, and furs, are far more important sections of the business of a draper than the heavier goods of the Manchester market. Indeed, so general has become the business that there seems scarcely any goods of a "fancy" character which the modern draper of any pretensions does not find it profitable to handle. It is not our purpose, however, to go into the departmental store system into which "drapery" has drifted, but rather to confine ourselves to what the Americans call the "soft goods" trade.

Apprenticeship. The best experience is obtained in a provincial house. In large towns, London especially, an apprentice may serve his three or four years in one department only; probably two or three, if he be fortunate. But in the drapery "emporium" of a good market town in the provinces he has an insight into all departments. Moreover, in such a business he has to take his turn in the counting-house, where he learns, if he will, how to keep books, how and what to buy, how to mark prices, and, in short, he is taught the business principles necessary for his success as a business man. The advantages of such a training as compared with that of a youth who has spent his four years apprenticeship in the "ribbons" or the "laces" of a large metropolitan house are too obvious to dwell upon. The indoor system is still the rule in the drapery business, but in some country houses in England, and everywhere in Scotland, outdoor apprentices are taken at a small weekly wage ranging from 6s. to 9s., as the period of apprenticeship lengthens and the youth becomes more useful.

Assistantship. Improvers who migrate from their training house to enlarge their experience generally get £20 or so per annum to start (in an indoor berth), and 9s. to £1 a week outdoors, the salary gradually increasing with the age, experience, and ability of the assistant to £50 or £100 indoors and a corresponding outdoor wage. In a large drapery house, it has been found that the average payment to the lowest female assistant was £47 per annum, and the average highest £105 per annum, plus board and lodging. The outdoor assistant generally gets dinner and tea in addition to a weekly wage. In most drapery houses nowadays commissions on sales and premiums on old stock goods (generally called "spiffs") are paid, the amount of commission varying according to the price of the articles sold, and it is quite a common thing in the larger houses for smart assistants to double their salaries by this means. It is surprising how this "spiff" system makes old goods new in the eyes of the assistant and how it enhances his, or her, selling capacity.

The aim of the embryo draper during assistantship should be to obtain as varied and diversified an experience as possible. He will probably have one pet department—laces, hosiery, or gloves, perchance—to which his tastes incline, and of that department he should know all that is to be known. But the other departments should by no means be neglected. "Know something of everything, and everything about something" is a motto which is as true in drapery as it is in other departments of life.

The New Start. All the huge businesses of to-day have had humble beginnings. It is said that the founder of the most famous drapery business in the country opened in a small shop with a capital of less than £200, while one of the best known business houses in the West End of London was started on £40. The opportunity and the man are the principal requisites of success in any sphere of work, and we will suppose that our man has gained as much experience as he reasonably can and that he has discovered what he considers to be his opportunity. We will imagine that the opportunity includes an ordinary shop with one large window in a likely neighbourhood and a sum of £300.

He should make it a point to choose a street in a neighbourhood where ladies especially promenade. He must see to it that he is on the right side of the street—that is, the side on which the greatest stream of promenaders pass. A cautious man will watch the shop he has in mind for a day or two before deciding, to make sure that there is a fair amount of traffic. The shop-fittings would not cost much. The prudent man will see that his painting and papering is carefully done, that the "shell of the shop," as it were, looks smart and inviting. Then all that is required is a long counter with a glass top and glass all round if possible, and ordinary shelving. Glass counters and shelving may often be bought secondhand for a very small sum. The whole should not cost more than £30, but it is advisable that the window fittings should be as natty as possible, especially if a trade in fancy articles is projected. And it is in fancy articles like hosiery, gloves, ribbons, lace, and things of everyday request, that the modern draper now begins business. Such things are easily and inexpensively stocked, they make a grand show, and they are quickly disposed of. The far-seeing man, by careful preliminary observation, may be able to gauge with fair accuracy the class of goods that will suit the neighbourhood. He should try to get a "special line," be it hosiery, gloves, or what not, well placed in the window to draw people into the shop.

Window and Wall Fittings. With regard to interior fittings, these necessarily vary according to the shape of the premises and the space at disposal. A very useful article to have is the double-sided dividing mirror shown in 1. It is in a polished wood frame mounted upon two wheel castors, so that it may be easily moved. The object, of course, is to divide a window into sections so that one window may be dressed with two different classes of goods without one clashing with the other. We also illustrate [2] an ordinary wall fitting with a counter and plate glass top, admirably suited for a beginner.

This is from a design by Messrs. Samuel Haskins and Brothers, of London, and the chief point in this scheme is that it has over-counter display rods, which enable the goods to be shown with great effect. The rails are carried by suspenders which are fixed to the top of the fitting, which must be specially constructed with bearers to receive it. The cost of these rails and suspenders complete would be about 8s. per lineal foot in 12 feet lengths and upwards. A variation of this over-rail idea is the "Zigzag Railing," as it is called, which allows of the goods being shown at an angle. The "Zigzag" costs about 12s. 6d. per lineal foot, measured in a straight line from end to end. The wall fitting consists of openings to receive either boxes, drawers, or packages.

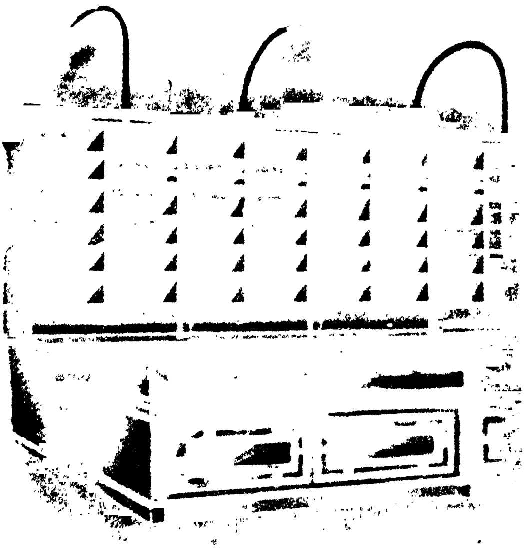
This class of fitting is made from 8 to 9 feet high, sometimes more, and the size of openings depends upon the class of goods or department it is used for. If, for instance, it be used for a ribbon stock, the openings should be about 18 inches across by 6 inches high, and fitted with glass-fronted drawers, so made that they are practically dust-tight. The goods in the drawers are kept undamaged and the glass-fronted drawers allow of a beautiful arrangement of colourings exposed to view. For such departments as laces, gloves, etc., the openings would be filled with cloth-covered boxes. The recess space is a feature of this class of fitting, dividing as it does the lower from the upper part of fitting, and also enabling one to form the lower part deeper than the upper part. When the recess is lined with mirror it affords a splendid opportunity to display goods.

Expense of Fittings. The cost of such a desirable fitting varies considerably with the size of the openings, but the price of a fitting similar to that shown would be about 35s. per lineal foot, without boxes or drawers. Glass-fronted drawers would be about 8s. 6d. each, and boxes from 3s. 6d. upwards, according to size and quality. The counter and case shown in front of the fitting are of a useful type. The lower part is formed with a tracery moulding and panelled front, pilasters, and plinth. The interior of this class of counter is usually fitted with a potboard, shelf and divisions forming a certain number of openings. In some counters the interior may be fitted with drawers, such as for haberdashery departments. The case over the counter should be made with ebony or black wood bars, and the whole glazed with polished plate glass. The flaps at the back of the case are hinged and fitted with spring catches and lined with mirror. Sometimes the bottom of the case is lined with mirrored glass, but in many cases in cloth, or with loose trays. The cost of such a counter would be about 30s. per lineal foot in 10 feet lengths and upwards, and the same for the case.

1. A VALUABLE MIRROR DEVICE FOR A DRAPERY WINDOW

A corner of one of the show-rooms in the trimmings and haberdashery department of Peter Robinson, Ltd., of Oxford Street, London, is shown in 3. It speaks for itself, and is a fine sample of interior display.

Establishing his Credit. A young man with £300 and a good record will have little difficulty in obtaining stock. The usual plan is for him to place his credentials before one of the large wholesale houses of good standing and, if accepted, to make that his "reference house." He then goes round to the wholesale dealers in silks, laces, blouses, outfitting, and so forth, tells each that he is starting in business, gives his orders, and refers them to the standard house. By this means he gets the supplies he needs and varying periods of credit. Here the much-abused system of "dating" comes in. If he buys on February 1st he can usually arrange to get immediate delivery, but the goods may be dated May 1st, and payment is not demanded until a month after that. The wise buyer will take advantage of full discounts for payment within the specified period, 2½ per cent. to 3 per cent. being the usual discount for a month. The advantage of such an arrangement to a smart man is obvious. It gives the energetic man an opportunity to turn over the stock and order a new lot by the time his first payment is due. As it is necessary that a draper's stock should be turned over at least four times a year, it will be seen that it may be possible for an able man with fairly good luck to turn over his stock within the twelve months without touching his capital.



2 A CONVENIENT DRAPERY WALL AND COUNTER FITTING

Buying. Great caution is necessary in buying. "Goods well bought are half sold," is a truism no young draper—or old one for the matter of that—should forget. Every traveller's goods should be inspected, for one never knows when one may hit upon just the thing one wants at a trifle less than another has shown. These small savings amount to something in a year. Be sure to get the full discount on every account. This is money earned at very little trouble, and should be watched carefully. Prompt cash will scarcely be possible at first, but it will be easier month by month. In many large businesses it is said that the discounts pay the salaries and expenses of the counting-house.

Amount of Stock. Always keeping in view the careful man feeling his way with £30 already spent in fittings, we pass on to the amount of stock necessary in order to make a presentable display. From £25 to £30 worth of hosiery would be required for a start, while £10 worth of ribbons would be ample. Then a fine assortment of laces could be obtained for £25, while corsets would run into another £20. Haberdashery is an important and profitable branch to cultivate. This includes cotton, thread, needles, pins, and such things, and £50 would not be too much to spend on that department. Baby linen and servants' aprons pay well, so £10 would be laid out on these, while £15 judiciously spent in a nice selection of blouses would produce a flattering return.

The foregoing computation applies more particularly to a start in the metropolis, or in some of the larger provincial cities and towns, where there are within easy reach large wholesale houses from which short stock can be quickly renewed. In a country town, a larger initial outlay would be necessary, but in all cases the methods pursued by the successful business men of to-day have invariably been to start with light stocks, and to keep buying little by little to fill up. The London man, with the finest wholesale houses in the world at hand, has many advantages over his country brother, but the provincial man has usually the benefit of less competition and better prices.

Specialising. As the tendency of the age is towards specialism, it is necessary that the young business man should take up some special line suitable to his neighbourhood, and push it. It is half the battle when the ladies of the neighbourhood are forced to recognise that for laces Jenkins is pre-eminent, or for baby clothes Hopkins cannot be beaten. The fame of a draper as a specialist by no means retards his development in other departments. His laces may be unrivalled, but he should see to it that the extra profit on laces should be used in making the dress stuff and other departments so complete that the lady who hankers for laces may also be induced to buy dresses.

The "ready-made" departments are popular —they are indicative of the feverish hurry of the present day. Blouses, skirts, jackets, and ladies' outfitting must be kept in all sizes and varieties ready for immediate use. The old fashion of buying goods by the yard and having them made up at home is almost dead. Sheets, pillow-cases, and towels must be ready-made, and in many cases, ready-washed. The up-to-date draper should also undertake to mark all household goods free of charge.

Ready-made Businesses. As a rule, it is better to start off one's own bat, so to speak, than to buy a going concern. This rule applies more particularly to businesses in a big town, for town people appear rather to prefer going to a new shop. The *blasé* inhabitants of large cities are ever on the look-out for new sensations, and a new adventure attracts them, more often than not, on account of its novelty. There are, of course, the usual exceptions which prove this rule. For instance, a man may buy for £200 a business which is dwindling from neglect, perhaps, or from want of enterprise on the part of the proprietor. Such a business may merely want new blood and brain to make its owner's fortune. There are many businesses of that type to be found advertised in the trade journals, and there are many other genuine businesses for sale in which the proprietors have made a fortune, but these are not to be purchased for £300. Therefore, the young man with limited capital and plenty of "go," if he contemplates starting in a large centre, usually passes over the businesses for sale.

The Provincial Business. In a country town, however, the exact converse holds good. There, local considerations make it necessary for a stranger, in order to get anything of a footing, to buy an old-established business. Country people are more conservative, less fickle in their tastes. They like to patronise the shop in the market place where their fathers, and maybe their grandfathers, have always bought. They like to look in on market days and order £10 or £20 worth of goods from people who have grown up in the town, and who know their idiosyncrasies. The "new start" has a rather quiet time of it for the first few years, until his standing, conduct, religious and political opinions have been accurately gauged, and he has broken down the cautious reserve of his neighbours.

When things are going all right, and the prospect of making a business seems certain, negotiations should be begun for taking a lease of the shop. Many a young man finds that when he has begun to build up a prosperous trade, the landlord considers it a favourable opportunity for increasing the rent. Such a contingency should be guarded against as early as possible in one's business career.

Profits. The average rate of profit in the drapery business is from 22½ to 25 per cent. It must not be forgotten that the stock should be turned over at least four times a year. Thus, a £300 stock turned over four times at a 25 per cent. profit, would leave a gross profit of £300 at the end of the year. Half, or more of that sum is required for rent, rates, etc., and working expenses, and the net profit would be probably £100 to £150. This is putting a rosy view on things, and excluding misfortunes, and we do not say that everyone will do that the first year, or even the second. But we are assuming that the adventurer knows his business, is careful, works hard, buys keenly, and takes full advantage of discounts. He would require to have at least two lady assistants—one costing probably £30 and the other £18 per annum and their keep—and one errand boy, who would receive, perhaps, 6s. a week. The profit made during the first few years should be put, of course, into the business. The stock in each department, or at least in the best paying departments, would be gradually increased. Improvements would be made in the shop-fitting. Glass cases may be added for the display of the finer class of goods, and in a year or two, perhaps, even a new shop-front may be put in, with a better window for displaying the tempting *lingerie* so dear to the feminine heart.

Profitable Departments. As has been already stated, it is the fancy goods on which the biggest profits are made. Millinery, ladies' underwear, hosiery, corsets, baby linen, blouses, jackets, and cheap furs, all command a quick turnover and good profit. On hats, a profit of at least 33⅓ per cent. is gained, and many of the shops in populous working-class districts nowadays use millinery more as

3. A CORNER IN THE DRAPERY ESTABLISHMENT OF PETER ROBINSON, LTD., OXFORD STREET, LONDON

Illustrating an approved manner of stocking and displaying goods

an advertisement than anything else. They advertise "Hats trimmed free of charge" as a draw, and in spite of the fact that they have to keep milliners to do the work, the profits are such on the bare material that it pays, not to speak of the custom it attracts. Mantles and jackets are also good articles for those who know how to handle them, and it is no uncommon thing for a smart man to turn over fourteen or fifteen patterns of jackets—costing, say, 14s. each, and selling at one guinea—eight or ten times during the year. Rabbit-skin furs that cost, perhaps, 2s. 9d., 3s. 11d., and 5s. each, sell like hot cakes at the first "nip of winter" at, say, 3s. 11d., 5s. 6d., and 7s. 6d. respectively. Costumes, coats and skirts, umbrellas, all bear good profits and sell quickly. The lowest profit is made on "Manchester goods"—true drapery. The average rate is from 17 to 20 per cent., and the stock is bulky, heavy, and slow of sale, but it must not be forgotten that in this there is little or no bad stock.

Credit. Except in solid, old-fashioned country concerns credit is practically unknown in the retail drapery trade. With small businesses cash is universally the case. In an old-established country establishment nearly half the business done is credit, and therefore a longer profit is necessary. It is a common thing to find in such businesses that the majority of the customers are never off the books. The servant girl comes in for a dress, she pays £1 down, and the balance remains. When she has paid off that she wants something else, and so it goes on. The farmer's wife purchases £20 worth of goods for herself and her daughters. She pays £10, and by the time she pays the other £10 she wants another £15 worth of summer wear. An elaboration of this system is practised on an enormous scale particularly in the Midlands and Lancashire by tallymen, or "Scotch drapers," as they are usually designated. These descendants of the ancient packman or travelling draper have regular rounds of customers in the districts in which they settle upon whom they call periodically with samples of dress-stuffs and drapery. The goods are delivered in the piece, or made up according to agreement, a sum is paid down, and the balance is collected in so many shillings weekly, fortnightly, or monthly as the case may be. Naturally, the purchaser has to pay considerably more than the value of the goods, but it is a convenience for poor people, and incidentally, the tallymen usually make small fortunes in a surprisingly short time.

The Bargain Sale. Twice a year, at least, the alert draper finds it necessary to institute a bargain sale. At the end of summer there is still on stock an accumulation of articles of a "summery" character which must be cleared. A light and airy summer creation in hats is no use for winter wear, and the fashion in hats will be totally different by the next summer. In like manner, when the spring sun begins to shine, the mantles, hats, coats, and furs of winter are undesirable, and the up-to-date man advertises his spring clearance sale. The experienced man, of course, marks his profits with a view to covering the losses incident from unseasonable stock being left on his hands, but, generally speaking, these bargain sales are very profitable transactions in spite of the "sacrifices." As a rule, however, the sales are genuine enough, in spite of popular cynicism. For at the time of the year, between seasons as it were, the wholesaler also is anxious to clear his surplus stock, and hats, for instance, that may have cost the retailer 2s. 6d. or 3s. each during the season, he may be able to purchase at 12s. per dozen. So that it may be stated by the retailer in all sincerity and with perfect truth that he is "now selling a hat at 1s. 6d. or 1s. 9d.," as the case may be, "which usually costs 4s. 6d." The periodical sales, however, are mainly useful in that they attract custom, and serve as outlets for remnants, oddments, and soiled stock. All that is wanted is an assortment of price tickets, and a stirring-up of neighbouring feminine curiosity by handbills, advertising in the local papers, mysterious preparations with brilliantly-lighted windows far into the night, and a preponderance of actual bargains.

The Secret of Drapery. One needs only to walk down the main street of any provincial town or suburb, or to stroll along the business streets in the West End of London to discover the secret of drapery. The observant stroller will note that the windows that attract most attention in any neighbourhood are those of the draper. The people who shop are the ladies, and if one sees a cluster of ladies congregated around a window, it is safe to assume that articles of feminine apparel are displayed therein. Other windows are glanced at casually, or, perhaps, something unusual attracts for a moment, but genuine interest is only attained when a well-dressed drapery window is reached. Thus the success of the draper depends, more than any other shopkeeper, on the variety, smartness, and magnetic properties of his window. The window show must be first of all attractive, but it must be varied constantly, and each show should be devoted entirely to one class of goods at a time.

Window Dressing. An arrangement of goods all of one colour is very attractive. In the summer nothing is more *chic* than a window dressed all in white. A draper should have the true eye for colours, as half a shade in colour makes all the difference between selling an article and not doing so. Therefore, i mixed colours are used, care must be taken that they harmonise [see also page 610].

A fresh window display every week, showing a varied assortment of ladies' wearing apparel, wi make the reputation of a draper within a year for that particular branch of trade. But ladies' underwear should not be thrust in the public gaze until it palls. A variation of laces, Manchester goods, blouses and skirts, or stoles, in between make the ladies' outfitting—with its cherished profit—come like something quite new again. Then the wide-awake man in business very soon discovers the needs of his neighbourhood, and caters for these needs. The failure of small businesses is due in a great measure to this neglect in gauging the wants of those for whom the proprietors should provide, and the consequent accumulation of dead stock which, metaphorically, hangs like a millstone round the unfortunate draper's neck.

Trade Protection. The draper newly started on his own account, and anxious to take advantage of all that is offered for his advancement, may find it advantageous early in his career to join the association known as the Drapers' Chamber of Trade. The objects of the association are to give legal advice and protection from vexatious prosecutions to members who pay an annual subscription. The beginner whom we have in mind would pay 10s. per annum to the Association, and for that the Chamber undertakes to help him in legal matters connected with his business, by prosecuting persons who defraud him, and to give him the benefit of "central" offices where he can make appointments. If a member, he will likewise have the benefit of a Plate Glass Insurance Scheme which saves 30 per cent. of premiums to insurers, and the Chamber is pledged to assist in opposing injustices to the trade, such as postal "cash on delivery," manufacturers obtaining unjust monopolies, carriers repudiating liability, secret commissions to buyers, and Acts of Parliament being passed likely to hamper drapers in their business. The question of reductions in fire insurance, an alteration of the law of debt, parochial contracts and bogus drapery companies, also engage the attention of the Chamber, which, in short, is promoted to keep a keen watch on all matters affecting the trade. Until the employer has over twenty employees, his annual subscription would remain at 10s. When he has over 20 and under 100 employees it will be £1 1s., and £2 2s. when there are 100. The offices of the Chamber are at 155–6, Cheapside, London, E.C.

Adventitious Aids. Many a large drapery business has been built up solely on advertising. An energetic man, hampered by unenviable surroundings, has often extended his operations to the whole country by a system of careful newspaper advertising, which has brought him not only fame but fortune. The "mail-order business," as it is called, has developed enormously of recent years. Orders by post are solicited by striking newspaper advertisements, and if the advertiser gives prompt attention to orders, and strives to send an article with which his customer can find no reasonable fault—in short, gives good value for cash—he is bound to succeed. He would, of course, pay carriage on goods amounting to a stated sum in value, but many of the more progressive men have found it pay to send orders for any amount (even for half a yard of lace) post free. The draper who essays to do this class of business must, however, have the "gift of advertising." He must know how to tell the public crisply and pointedly what to buy and what he sells. His announcements must be distinctive and above all they must be persistent. A sudden and violent rush of sensational advertisements and then a sudden silence is likely to be worse than useless.

The Commercial. A good plan for the draper's assistant who aspires to proprietorship, and who would learn commercial wisdom in a good school, is to engage himself as a commercial traveller for a time to a reputable wholesale house. This is easier said than done. But if a young man sets out in life with a definite aim, he will be wise to keep this contingency in view as his ultimate period of service under an employer. Having gained an inside knowledge into retail methods in all departments of retail drapery—and their name is legion—he might attain to the coveted position of buyer in a large drapery establishment. Such a position brings him directly into contact with wholesale houses, and a smart man "of good appearance and address," according to the stock description, should have little difficulty in obtaining a post as provincial representative in a house that knows his value. Of course, most representatives are bred "in the house," but there are exceptions and the competent buyer who badly wants such a position should not have long to seek for it, even though he has not grown up with the business. The amount of business information and the varieties of methods which the observant commercial can acquire in his journeys through the country will prove invaluable when finally he launches into business on his own account.

The extent to which the drapery business may be developed is indicated by a walk through one of the large establishments in town or country. There will be found under the same roof and under the same control, departments—separate and distinct—devoted to baby linen, Berlin wool, clothing, outfitting, carpets, dressmaking, millinery, furs, gloves and hosiery, haberdashery, hats, silks, umbrellas, and sometimes furnishing, all of which are the subjects of individual articles in this course.

Transatlantic Methods. The hustling methods of our American cousins are much vaunted by some modern business men, and probably Britishers might learn something from the Americans. But American methods are slow of adoption in this country, and Britishers smile indulgently at Wanamaker's lectures to assistants "on the rules of business," "the conduct of business," or "the way to treat customers," preferring the less academic but more practical training of their forefathers. The card system for keeping the books is not catching on in this country, but the same system as applied to "follow-ups" is having something of a vogue in some quarters. The large and distinct departments into which the successful draper gradually divides his business make the application of this system possible, in that the heads of each department can "keep track of trade," and follow up with circular and otherwise any customer who has ever bought anything and has had occasion to leave name and address. In America, also, the "sales operator" is an institution practically unknown to this country. He takes in hand to get rid of your stock in the shortest possible time, at a profit, to make your sale "the most successful ever held," to write your advertisements, and to advise you generally. All of which may be very useful occasionally, but the fortunes in drapery, as in every other trade, are built up by men who know their own business best, and who have neglected none of the teachings learned in the hard school of personal experience.

Useful Literature. The man who desires to keep conversant with current events must subscribe to at least one of the many trade papers which deal solely with the drapery business. A series of useful business books are issued by the Home Trade Publishing Company, such as "Bookkeeping for Retail Drapers," 2s. 6d.; "Window Dressing for Outfitters," 2s. 6d., etc. Naismith's "Young Draper's Guide to Success," 1s. 6d., published by Gardner, of Paisley, contains many useful hints for beginners, while the more advanced man will have by him a copy of the "Draper's Dictionary," by S. W. Beck, which is published, at 3s. 6d., by Collinridge.

STEEL-FRAMED STRUCTURES

Cantilevers. Warren Girders. Lattice Girders. Trellis Girders. Braced Girders. Whipple-Murphy Trusses. Trussed Beams

By Professor HENRY ADAMS

Steel-framed Buildings. In a steel-framed building there will usually be three conditions of loading for the stanchions. Those in the interior have the heaviest load to carry, but it is generally applied symmetrically on two or four sides; those on the exterior, except the corner stanchions, will have two loads on opposite sides, and another load on a third side, and those at the corners will have two loads on adjoining sides. In the first case, the total load will be greatest, but will be nearly, if not quite, balanced; in the second case, the load will be less, but as it will be only partially balanced, the total effect will not be reduced; in the third case, the load will be still less, but will not be balanced at all, so that approximately each case will require the same size of stanchion.

Solid Steel Pillars. For intermediate supports to girders in shop fronts, theatre balconies, etc., the minimum obstruction to the view, with the requisite strength, is obtained by the use of solid steel cylindrical pillars, with cast-iron or cast-steel caps and bases. These pillars may be calculated by the formula

$$W = \frac{fA}{1 + a\left(\frac{l}{d}\right)^2}$$

where W = safe load in tons, f = safe compressive stress on short specimen = 5 for mild steel, A = sectional area in square inches, a = constant $\frac{1}{3000}$ for ends flat and fixed, l = length in inches, and d = diameter in inches.

Cantilevers. Cantilevers may be in the form of beams, rolled joists, or girders built into a wall or rigidly connected at one end, with the other end free and projecting. The load supported by it may be concentrated at the free end or at any intermediate point, or may be uniformly or irregularly distributed along it. The load may be quiescent or "dead," it may be a vibrating or "live load," or it may be a more or less suddenly applied load producing impact or shock. All these varied conditions produce different amounts and distribution of stress. The more common cases are shown in **157**, where the maximum bending moment is equal to WL, and in **158**, where the maximum bending moment is equal to $\frac{1}{2}wL^2$, w being the load per foot run and L the span in feet.

Brackets. Brackets are cantilevers of more complex shape, the simplest being in the form of a triangle as **159** and **160**. Whatever the detail of the arrangement the principle of the stresses is as shown. Taking the case of **159** with a load at the end, the tension in the horizontal part will be $= W \times \frac{L}{D}$, and this will be the amount of horizontal pull on the wall at the top and thrust at the bottom. The weight also produces a downward thrust at the bottom = W. The thrust in the inclined portion will be $= W\frac{\sqrt{D^2 + L^2}}{D}$. The stresses may be shown graphically by reciprocal diagram as in **161**. First number the spaces between the external forces 1, 2, 3, 4, and the internal space 5. Then in **161** draw the load-line 1–2 equal to the load to any given scale, and from points 1 and 2 draw lines 1–5 and 2–5 parallel to the lines in **159**, separating spaces 1–5 and 2–5. Then, 2–3 being equal to 1–2, point 3 will be the same as point 1, and as there will be no stress in 4–5 of **159**, these two points will come together in **161**. Scaling off the lengths of the lines in **161**, the stresses will be found to agree with those shown by calculation above.

The case of **160** cannot be completely determined by a reciprocal diagram alone, as these diagrams do not take account of transverse stress. In numbering the spaces the distributed load must be taken as equivalent to half concentrated at each end, so far as the stress on the frame is concerned—*viz.*, as forces 1–2 and 2–3; then in the reciprocal diagram **162** the load-line 1–2, 2–3 will first be drawn to scale, and point 6 will be found by drawing 2–6, 3–6 parallel to the corresponding lines in **160**. Then 1–5, 6–5, and lastly, 5–4, being equal to 1–5, 1 and 4 will be at the same point. Before going further it will be well to note that the nature of the stress is determined as explained in connection with the triangle of forces on page 1834. Taking the joint in **160** surrounded by the spaces 1, 2, 6, 5 (clockwise), 1–2 is a force of known direction acting downwards, then 2–6 in **162** is away from the joint indicating tension, 6–5 is towards the joint indicating compression, 5–1 is away from the joint indicating the pull at the wall. Again, taking the joint at 2, 3, 6, 2–3 acts downwards, then 3–6 acts towards the joint showing compression. The effect of the distributed load in producing transverse stress will be given by the bending moment formula $\frac{WL}{8}$ as in the case of a beam, which gives the height of the parabola in the centre. There are thus two forces acting, the direct tension and the transverse stress. These are combined by the formula $\frac{W}{A} \pm \frac{M}{Z}$, where W is the direct load, A is the sectional area of the upper member, Z its section modulus [page 1984], and M the maximum bending moment. The plus value will give the stress in the upper surface of the member, and the minus value that in the lower surface. One other point of difference between **159** and **160** should be noted.

STRESSES IN GIRDERS

The wall piece in 159—*viz.*, 4–5—has no stress, while in 160 it is in compression due to carrying half the load.

Braced Cantilever. The reciprocal diagram affords a ready means of ascertaining the stresses in a braced cantilever as 163. Draw the load-line 1–2 in 164, then note that point 9 must be next found by drawing lines 1–9, 2–9; then 9–8, 2–8, and so on, always working from two known points to obtain the unknown third point. The remainder presents no difficulty. The nature of the stresses may be conveniently indicated on what is called the *frame diagram*, 163, by thin lines for tension, thick lines for compression, and dotted lines for no stress.

Braced Beams. A short braced girder in three bays of the Warren type is shown in 165. Taking the load as 12 tons distributed along the top flange, there will be four tons on each complete bay, so that the distribution will be as marked and the reactions will each amount to half the total load—*viz.*, six tons. A little more than half this girder is shown in 166, and the method of finding the stresses by parallelogram of forces is indicated by dotted lines, commencement being made at the abutment. A load of one ton from the end pillar does not pass through any of the bracing, so that this being deducted from the reaction, leaves five tons to be resolved into the directions B*g* and B*d*. Tension and compression may be conveniently indicated by the signs – and +. Transferring the stress in B*d* to its upper end, it is combined with the load on *d* to give the resultant *hd*; then the stress in *hd* is resolved into the directions *dg* and *de*. The stress in *dg* is then transferred to the lower end, and its effect found in the directions of *ge* and *gf*. In the latter case the stress in B*g* must be added to give the total stress as shown by the figures below. The same method may be continued through to the other abutment, when the reaction there will be found to balance exactly the stresses in the bars meeting at that point. This method is not so simple or convenient as that to be now described, but there are cases where it will sometimes throw light upon doubtful cases and enable them to be worked out satisfactorily.

Girder Stresses by Reciprocal Diagram. The same girder [165] may now be taken to illustrate the use of reciprocal diagrams. It is shown in 167 prepared as a *frame diagram*, and 168 shows the corresponding *reciprocal stress diagram*.

Another girder with irregular loading is shown in 169 prepared as a frame diagram. The reactions may be calculated or found graphically as follows. The line of loads 1–2, 2–3 is drawn to scale in 170, a pole, 0, is taken at any point and vectors drawn from points 1, 2, 3, the force lines in 169 are produced, and anywhere on the reaction 1–4, as at A, a commencement is made for the funicular polygon. Then, from A, parallel to the vector from 1, a line is drawn across space 1; this is continued across space 2 by a line parallel to the vector from point 2, and across space 3 parallel to vector from 3, meeting the other reaction in B. Join BA and from the pole 0 draw a parallel line to cut the load-line in 4, then 3–4 will be the reaction on the right-hand side in 169 and 4–1 the reaction on the left-hand side. Having found point 4 on the load-line, the reciprocal diagram may be completed as shown without further difficulty, except that 4–5 will come at the same point, showing no stress in that bar, and 3–12 will also occur at one point. Although there will be theoretically no stress in these bars they are put in for appearance and to provide against contingencies.

Lattice and Trellis Girders. Lattice girders [171] and trellis girders [172] may be worked in precisely the same way. Lattice girders with verticals [173] are strictly indeterminate structures, as the stresses in the various members depend to some extent upon the workmanship. It is generally assumed that half the load upon any apex, whether tension or compression, passes through the vertical member, and this is borne out by investigation when the girder is divided into its two component forms with half the load taken upon each. The method of doing this is shown in 174 and 176, the corresponding stress diagrams being 175 and 177. The sum of the stresses being collected, a single stress diagram may be constructed from them as in 178, which is to a smaller scale. This form of girder has been largely used for bridges, as, for example, the Charing Cross railway bridge.

Whipple-Murphy Truss. Other types of girder, such as the Pratt [179], the Howe [180], and the modified Pratt [181], have been used very frequently for timber bridges in America, but the type perhaps most favoured at the present time for steel construction in spans of 60 ft. to 100 ft. is the Whipple-Murphy truss [182], also known as the Linville system. The calculation of the stresses in this girder occupy many closely printed pages in works on structural mechanics, but the principle just illustrated of dividing a complex girder into its component parts, each with its due share of the total load, may be conveniently applied to this case.

Trussed Beams. A simple trussed beam, as 183, is used for trussed purlins, small gantries, etc. The frame diagram shows that the distributed load must be indicated by force lines of the proper value over each of the points of support, and the stress diagram [184] may then be drawn. When the end thrust in the horizontal member is scaled off, it must be combined with the bending moment of the load between the points of support producing a transverse stress, by the formula already given—*viz.*, $\frac{W}{A} \pm \frac{M}{Z}$. For large spans it is necessary to have two struts, as in 185, and the stress diagram for a uniformly distributed dead load is shown in 186. With an irregularly loaded or partially loaded beam, or a rolling load, the truss will require bracing between the two struts, otherwise, when the load is over one strut, there will be a tendency to lift the other strut.

ITALY, SPAIN, & PORTUGAL

Build of Italy. Climate, Products, Towns, and Features of Interest. Physical Characteristics and Towns of the Iberian Peninsula

By Dr. A. J. HERBERTSON, M.A., and F. D. HERBERTSON, B.A.

ITALY

From the summit of any lofty Alpine peak south of the Rhone Valley—Monte Rosa, for example—a wonderful view is seen to the south. Vast and blue extend the plains of Piedmont and Lombardy, rich lands built up in the course of untold ages at the southern base of the Alps, and formed of the sediment carried down by the rivers descending from their snow-fields and glaciers to the Po, which, on a clear day, may be made out like a silver thread in the blue distance. The valleys opening to this plain are even more beautiful than those opening north, and the lakes which fill many of their lower ends—Maggiore, Lugano, Como, Garda, and smaller ones—have an indescribable charm of southern loveliness.

West of the Adige, all the Alpine streams descend to the Po, which flows almost due east to the shallow Adriatic, into which its delta is steadily pushing. Its tributaries on the southern bank come from the Apennines. These mountains, which form the backbone of Italy, spring from the Maritime Alps, skirt the shore of Liguria, and broaden out across the centre of the boot-shaped peninsula, leaving narrow lowlands along the sea on either side. The island of Sicily, separated from Calabria by the Strait of Messina, is structurally a continuation of the Italian peninsula. The mountainous islands of Corsica (French) and Sardinia, separated by the Strait of Bonifacio, rise out of deep seas to the west.

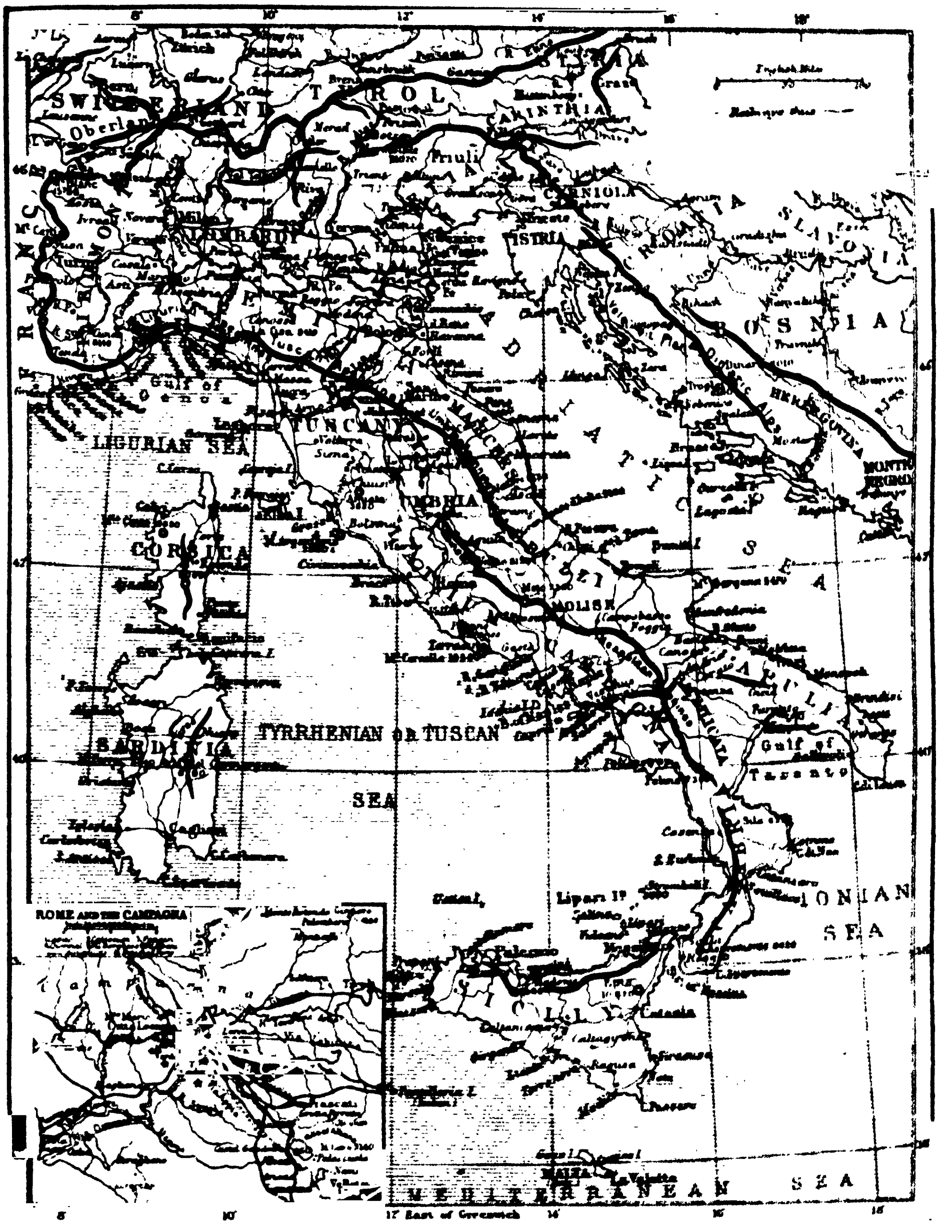
Climate and Products. The climate of Italy (110,500 sq. miles) is everywhere genial, and Sicily enjoys something not unlike perpetual summer. The severest winters occur in the plains north of the Apennines, but even there frost never lasts long. The summers are everywhere hot. Round the northern plains the rainfall is about 40 in. a year, and fairly uniform at all seasons. Further south it diminishes considerably, and occurs chiefly in winter. Evergreens replace deciduous trees, and the cypress, stone-pine, and evergreen oak give a wholly new character to the landscape. The characteristic Italian tree is the olive, which is grown, along with vine and mulberry, in the valleys opening to the plain of the Po, but not on the plain itself, owing to the severity of the winter. In summer this plain is hot enough for cotton and rice to be grown. The vine is cultivated everywhere. Maize is a common cereal, and a special hard wheat, used for macaroni, is grown in the south in Apulia. Agriculture is the principal occupation, but manufactures—silk and other textiles, engineering, and electrical works—are rapidly becoming very important in the northern plain, which is the most prosperous and progressive part of Italy.

Northern Italy. The traveller enters Italy either by the Mont Cenis route, which brings him to Turin, with its streets like the squares of a chessboard and its fine view of the neighbouring Alps, or by the St. Gotthard route, which brings him to Milan, with its brown roofs, many bell-towers, and immense cathedral of white marble. Milan is the busiest town of Italy, silk being the most important of its many manufactures. From Milan we may go east by Verona, at the end of the Brenner route, and the old university city of Padua, to Venice, a city of lagoons and islands, with the magnificent cathedral of St. Mark, and, instead of streets, canals flowing between lines of palaces. Or, instead, we may go south, cross the Po at Piacenza, and pass by the famous old towns of Parma and Modena to the picturesque university city of Bologna, built at the base of the Apennines, and commanding the route across them into Tuscany. In either case we traverse a vast fertile plain, enclosed between the Alps and Apennines, crossed by a network of irrigation canals, and green with rich crops of cereals and fruits of many kinds.

Liguria and Tuscany. These provinces lie west of the Apennines. Liguria is favoured both in scenery and climate. The mountains which shut it in on all sides except the south keep off all cold winds, and its rocky shores are a dream of sunlit beauty. Genoa, often called the "Queen of the Mediterranean," is a city of palaces, built round a magnificent bay backed by mountains. Its commerce is enormous. Further south is Spezzia, the Italian naval station.

Tuscany slopes from the crest of the Apennines to the blue waters of the Mediterranean. Its largest river is the Arno, on which is Florence, a city no less famous for art treasures than for natural beauty, built a little below the point where the Arno leaves the Apennines. Near the mouth of the Arno is Pisa, with a grand cathedral and the famous leaning tower, once a prosperous port, but long superseded by Leghorn (Livorno) to the south. North of Pisa is Lucca, famous for oil. All Tuscany is hilly, and many of the towns—small, but often rich in masterpieces of architecture and painting—are built on the crest of steep hills above terraces of vineyards and olive yards, which yield the famous Tuscan wine and oil. Such a city is Siena, with a magnificent cathedral and art galleries.

The Tiber Basin. Similar in character, but less fertile, is Umbria, the basin of the Upper



99. ITALY

Tiber. The most famous cities are the hill towns of Perugia and Assisi, both rich in art treasures. The Lower Tiber opens to the wide plain of the Roman Campagna, once richly cultivated and densely peopled, but now covered with ruins, and inhabited only by scattered shepherds.

The Eternal City. Rome, world famous for 2,500 years, is built on several low hills rising out of the level Campagna, which, except on the seaward side, is shut in by wooded mountains. To the stranger entering it by rail it looks a modern city, but his first drive overwhelms him with monuments of Pagan splendour—the Forum, with its ruined temples; the great amphitheatre of the Coliseum, triumphal arches and columns, pillars of heathen temples built into Christian churches, the long avenue of Roman tombs lining the Appian Way, and the great ruined aqueduct stretching across the

Campagna. Innumerable magnificent churches and palaces and the immense cathedral of St. Peter's tell of the splendour of Papal Rome. In every sense it deserves the name of the Eternal City.

The Campagna of Naples. This is separated from the Roman Campagna by a tract of marshes, which are rendered uninhabitable by malaria, the scourge of Italy. Naples is built on a magnificent bay near the base of Vesuvius, an active volcano whose eruptions are often on a most disastrous scale. The surrounding plain is one of the most fertile parts of Italy. The coast is famous for its beauty, especially about Amalfi and Salerno.

On the opposite side of the Apennines are the thinly-peopled mountain lands of the Marches and the Abruzzi and the fertile lowlands of Apulia, with many good harbours, including Brindisi, the terminus of the overland route to the East.

Calabria, the toe of the Italian boot, is a thinly-peopled mountain region, with picturesque towns on the coast.

The Italian Islands. Sicily, south of Calabria, is the garden of Italy. Agriculture is backward, but the fine volcanic soil is extraordinarily fertile. Cereals and fruits, especially orange and lemon, come to perfection, and in old times Sicily was the granary of the world. In the north-east is the active volcano Etna, over 10,000 feet high. Sulphur is abundant, and exported in large quantities. The chief towns, all on the coast, are Messina, on the strait; Catania, at the base of Etna; and Palermo, on the north coast.

North of Sicily are the volcanic Lipari islands, one of which, Stromboli, is often called the Lighthouse of the Mediterranean. South of Sicily are the British islands of Malta, with the fortified naval station of Valetta, and Gozo. Early vegetables are grown.

Sardinia, the only other important island, is mountainous and thinly peopled. Agriculture is backward, but the soil is fertile. The mining of iron and other ores is carried on, and also in the small island of Elba, off the coast of Tuscany.

SPAIN AND PORTUGAL

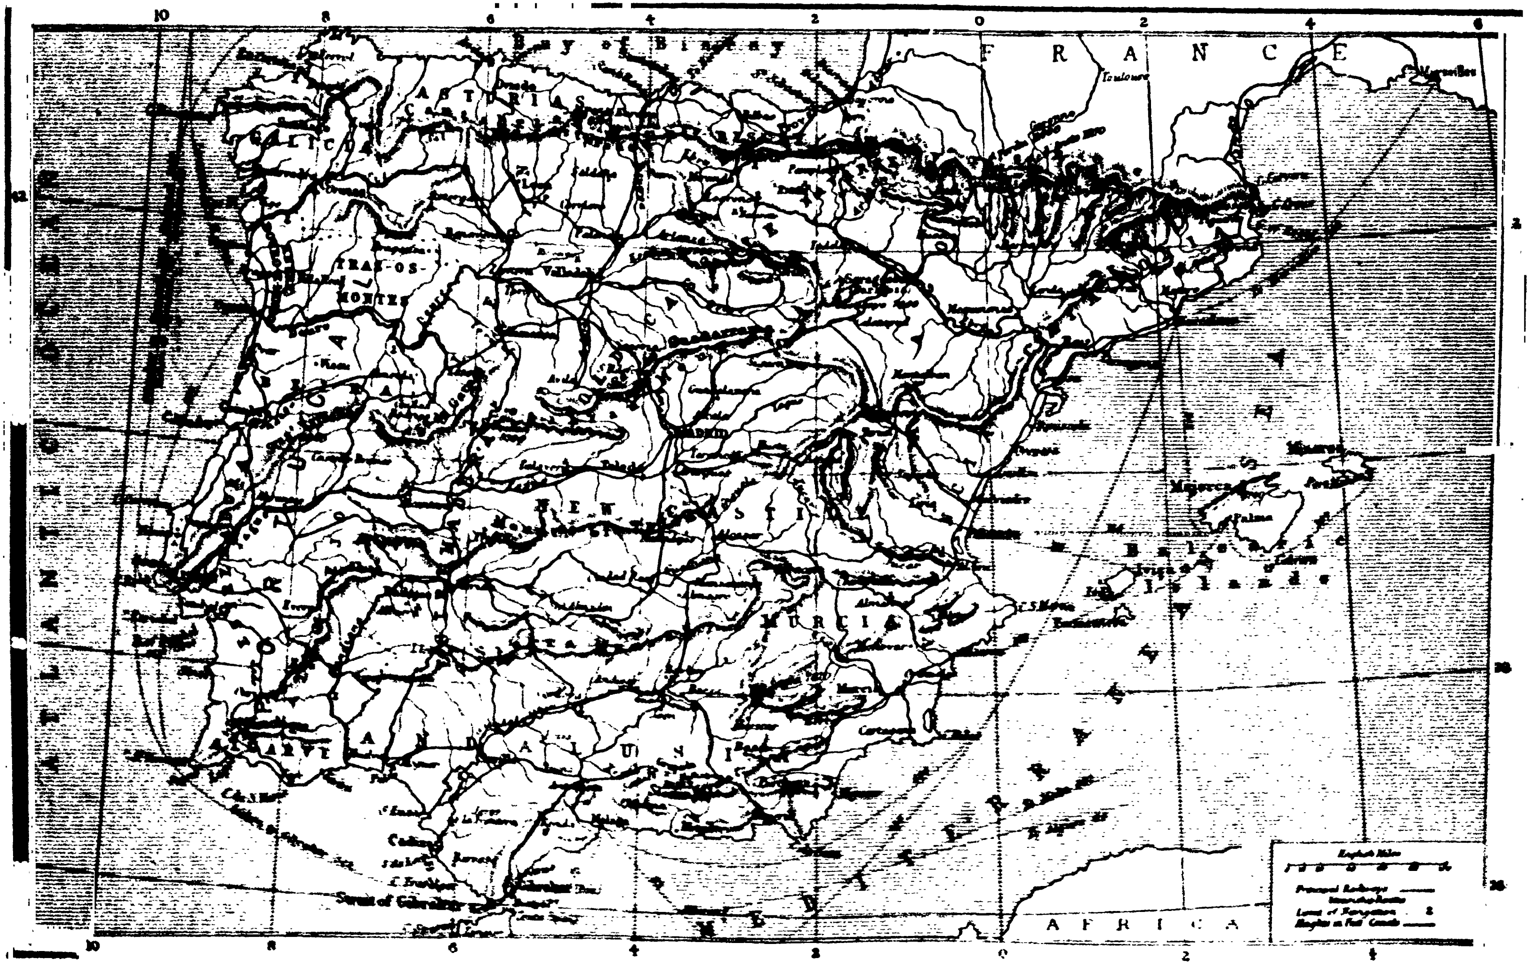
Iberia. This name is commonly given to the westernmost of the Mediterranean peninsulas, which is divided politically into the kingdoms of Spain (192,000 sq. miles) and Portugal (34,500 sq. miles). The only land frontier of Iberia is in the north-east, where the Pyrenees form the frontier of France for over 250 miles. On the north, west, and south-west it is washed by the Atlantic, and on the east and south-east by the Mediterranean, the two being connected by the narrow Strait of Gibraltar, where the fortified rock of Gibraltar guards for Britain the road to India.

Mountains and Rivers. Next to Switzerland, Iberia is the loftest region in Europe, only a small part of the peninsula being less than 1,500 ft. above the sea. The Pyrenees are continued in the east to the south-west by the mountains of Catalonia, and in the west by the Cantabria Mountains, rich in iron and other mineral and rising steeply above the Bay of Biscay From the western and eastern ends respectivel of the Cantabrian Mountains come two importan rivers—the Minho, flowing south-west to th Atlantic, and forming part of the boundar between Spain and Portugal, and the Ebr flowing south-east to the Mediterranean acros the large lowland of Aragon. West of the Ebr rises the Meseta, an immense lofty plateau with a general elevation of over 2,000 ft., formin the core of the peninsula. It is highest in th east, and the rivers which flow to the Mediterranean are consequently short and rapi The longer rivers—the Douro, Tagus, an Guadiana—follow the westerly slope of th Meseta to the Atlantic, flowing in deep gorge sunk below the level of the surrounding country They are consequently difficult to cross, and a they are too swift and shallow to be navigable they are useless as a means of communicatio Jagged lines of heights called sierras (Sp. *sierra* saw), rising some 5,000 ft. above the Meseta separate them from one another. South of th Guadiana the southern margin of the Meseta called the Sierra Morena, descends steepl to the lowland of Andalusia, which is crosse by the Guadalquivir, the most important rive in the peninsula. Its waters come from the Sierra Morena and the Sierra Nevada, the latte forming the south-east heights of Spain. Thi lowland and that of Southern Portugal, roun the Lower Douro, are the most important lowlands of the peninsula. Those of the east coas are small, but highly cultivated, especially i Murcia and Valencia.

Natural Regions. Iberia consists of three well-marked regions—(1) the Pyrenees region including the Catalonian and Cantabrian Mountains; (2) the Meseta; (3) the Andalusian region with the lowlands of Southern Portugal an South-eastern Spain.

The Pyrenees. The Pyrenees regio belongs in climate and vegetation to Centra Europe. The rainfall of the Cantabrian Moun tains is heavy, while the rest of Iberia is very dry. The seaward slopes are densely foreste with deciduous trees. The summers are warm but frosts are common in winter. All the plant of Central Europe can be grown, including the vine and apple, from which wine and cider are made.

The Meseta. The Meseta is high, bleak, dry, and extreme in climate. The temperature o Madrid varies from a maximum of 104° in summe to a minimum of 14° in winter, a range of 90°. Evergreens replace deciduous trees, and in the lower west vast numbers of swine are fed in the evergreen oak forests of Estremadura. A valuable species is the cork oak, whose bark furnishes cork. The higher parts of the Meset are too bleak for trees. Much is covered with poor grass or low evergreen aromatic plants, which supply thousands of sheep and goats with their summer pastures. Agriculture i backward, and much fertile land is unused. Water for irrigation is difficult to obtain, as the

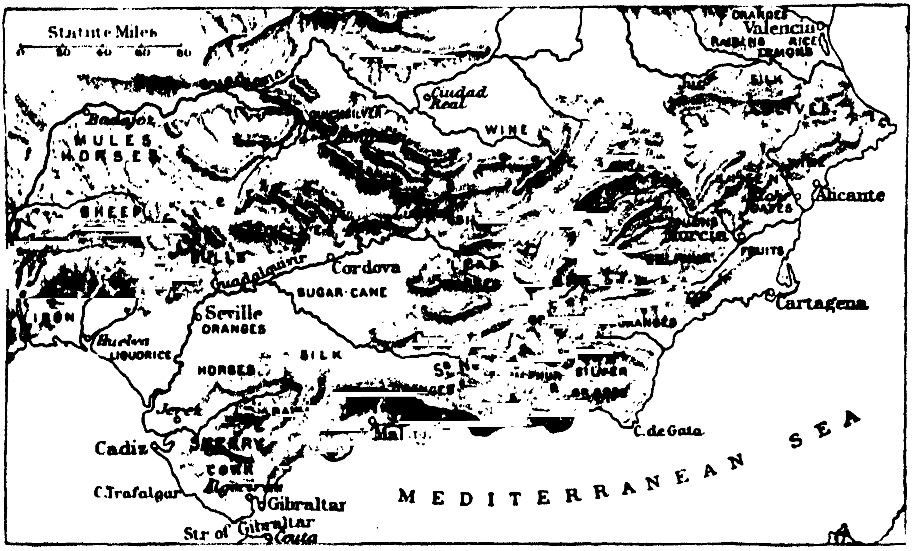


100. THE IBERIAN PENINSULA: SPAIN AND PORTUGAL

rivers are deeply sunk in inaccessible rocky gorges. Wheat is grown where ground-water is found near the surface, but under less favourable conditions only barley, oats or rye are sufficiently hardy.

Andalusia. Andalusia and the other lowlands of the south differ from both these regions. The climate resembles that of Northern Africa, and in the better parts are grown many plants belonging to the tropics. Among these are the date, which ripens at Elche in Valencia, the banana, sugar-cane, sweet potato, cotton, and, in swampy districts, rice. The orange, fig, mulberry, and other Mediterranean fruits are almost wild. Some wheat and maize and many pulses are grown. The vine is very extensively cultivated. The ports of Portugal and the sherries of Southern Spain are world famous. Raisins, or dried grapes, and dried figs, are exported in immense quantities from the ports of Valencia and Murcia, where much attention is devoted to irrigation and agriculture. "The rock has to be blasted and then powdered with hammers to form soil, the slopes of all the hillsides are terraced, and every fertilising agent, even the sweepings of the streets, is utilised." Unfortunately such a spirit of enterprise is rare in Spain. The agriculture of Andalusia is backward, though its mines, largely developed by foreign capital, are prosperous. It is famous, too, for its bulls and horses.

Towns. Towns are more numerous on the coast than on the plateau, which is thinly peopled. On the north coast are the ports of Bilbao and Santander, exporting iron. In the Douro basin are Valladolid, in the middle of the plateau, commanding the route to Madrid across the Castilian mountains, and Oporto, on the coast of Portugal, exporting port wine. In the Tagus basin are Madrid, the capital, in the middle of the plateau among bleak surroundings; Toledo, finely situated above the river, and long famous for fine swords; and Lisbon, the capital of Portugal, built on hills at the mouth of the broad Tagus. There are no towns of importance in the Guadiana basin, but a little further east is Huelva, which exports the copper of the Rio Tinto copper mines of the Sierra Morena. The Guadalquivir recalls the Oriental magnificence of the Moorish conquerers of Spain. Granada, at the base of the Sierra Nevada, contains the Alhambra, one of the most exquisitely beautiful buildings in the world. Cordova has a magnificent cathedral, once a mosque. Seville is the most prosperous city of Andalusia, with tobacco and manufactures, and a large trade. All the ports of the south and south-east coast—Cadiz, Malaga, Almeria, Cartagena, Alicante, and Valencia—trade in fruit and oil. Cadiz exports the sherry of Xeres. Barcelona is the chief city and port of Catalonia, the one part of Spain which is progressing industrially. Its manufactures and trade are very important.



101. ANDALUSIA

Off the east coast are the Balearic Islands. The largest town is Palma, on Majorca, the largest island.

Continued

BRITISH BREEDS OF CATTLE

The Most Suitable Breeds for Beef and Milking. Oxen for Farm Work. Breeding. Care of the Calf. Indications of Age

Continued from page 2079

By Professor JAMES LONG

THE varieties of cattle bred in the British Islands are unquestionably superior, as a group, to those bred in any other part of the world. There is nothing comparable with the Shorthorn or the Hereford, the Devon or the Aberdeen Angus, as meat producers, or with the Shorthorn, the Ayrshire, the Jersey, and the Guernsey, as milkers, among the scores of varieties which abound on the European continent. Our leading breeds are precisely those which have been imported into America, our Colonies, and foreign countries for the improvement of local stock, and thus it is that we have been supplied with superior beef and dairy produce for the feeding of our people.

The Shorthorn. The Cattle King is the Shorthorn [page 22]. It is at once, if we embrace the pedigreed and the unpedigreed stock, the most useful, general purpose beast best known to men. It thrives on almost any soil, and in every climate. Known as the Durham on the Continent, it is a beef producer of the first rank ; it improves almost every race or mongrel when employed as a cross, and in the shape of the well-known dairy Shorthorn of our country it is perhaps the best milker which is known, if we estimate the value on the basis of the quantity as well as the quality of its milk. It varies in colour from red, white, and roan, to combinations of reds and whites, and roans and whites.

The Shorthorn is a beast of gentle disposition, a rapid feeder, carrying a soft, mellow skin and a silky coat. It is square in build, with straight top and bottom lines ; neat, small, curved horns ; great width of loin and hind quarters ; deep, well-sprung ribs ; ample girth round the heart ; full eyes ; neat, well-formed head, with a somewhat large muzzle, adapting it as a powerful grazer. The weight of the fat Shorthorn may be better realised from examples. At the Smithfield Fat Cattle Show of 1905 the King's champion heifer weighed 16 cwts. 3 qrs. 20 lb. at two years eleven months old, having thus made a gain in live weight of 1·8 lb. daily from birth. His Majesty's champion steer, aged two years nine and a half months, reached the extraordinary weight of 19 cwts. 1 qr. 25 lb. The best milking cow unpedigreed at the National Dairy Show in the same year produced six gallons of milk in the milking trials and 2 lb. 13 oz. of butter in the official test. In Lincolnshire a variety of Shorthorns, known as the Lincoln Red [page 431], is bred for beef and milk production. The most famous milking herd of this breed is owned by Mr. John Evens, of Burton, and, numbering forty-three head of cows, produced an average yield, in 1904, of 842 gallons, while the same herd, with the same number of animals, averaged 889 gallons in 1896. Mr. Evens's marvellous results are the work of successful breeding on the principle of selection during some fifteen years.

The Hereford. Practically a local breed confined to Hereford and a few adjacent counties, the Hereford is, nevertheless, bred largely in America and the Colonies, its value for crossing for beef production being almost as remarkable as that of the Shorthorn. In colour it is dark red and white, the white markings being quite characteristic, and covering the head, crest, chest, belly, tail-end, and often the feet and legs as high as the knees. The horns are rather long and spread. The disposition is gentle, the skin mellow, the buttocks full, and the body deep, thick, and blocky. The Hereford is hardy, and useful as a working ox, but the cows are poor milkers, sometimes being unable to properly rear their calves. The champion steer of 1905, owned by the King, weighed 17½ cwts. at the age of two years nine months ; but the heaviest animal at Smithfield in the same year was Lord Coventry's steer, aged two years eight and three-quarter months, weighing 18 cwts. 2 qrs. 7 lb.

The Sussex. A dark red animal, of a rather long-horned race of coarser type, still used as a working ox on the Sussex Downs, is called the Sussex. It has been much improved during the last decade, but much is needed before it can be regarded as a symmetrical beast. It is massive in appearance, hardy in constitution, matures early, and produces meat with less fat than some of the more famous breeds. The cows are poor milkers, while the variety is chiefly confined to Sussex and its vicinity.

The Devon. The variety called the Devon is similar in colour to the Sussex, being a rich dark red, and presenting a mottled appearance with its new coat. It is, however, smaller, and more compact, with good, symmetrical lines and meat of high quality. It does not reach so great a weight for age as the Shorthorns, the Herefords, or the Aberdeens, but is largely bred in Somerset and Devon, as well as in many other parts of the country. The horn is stout in the male, though finer in the female, and of medium length. The Devon is quite a moderate milker, but hardy, profitable, and attractive, feeding well for the butcher.

The South Ham. A sub-variety of the Devon is known as the South Ham. This animal is chiefly bred in South Devon, and perhaps more extensively for milk than for beef production. It possesses a rich, soft, yellow skin, is a large producer of unusually rich milk, and is mainly responsible for the richly-coloured butter and clotted cream so largely produced in that part of England. Perhaps the finest herd of South Devon cattle is that owned by Mr. Vosper, of Merafield, near Plympton, and numbering 200 head.

The Longhorn. The most picturesque of English varieties is the Longhorn. It is a big, plainly-formed animal, with a huge curved horn growing downwards and inwards, while it varies in colour between brindle, roan, red, and even pied. The variety, long neglected, is being revived, but much is needed before it can be regarded as an animal of the first rank. The steers reach great weights, but do not carry sufficient meat on the best parts, while the cows are poor milkers.

The Red Poll. The Red Polled cattle are peculiar to East Anglia [page 432]. They are hornless, a rich chestnut red in colour, compact, and sometimes even massive, of medium height, symmetrical in form, docile in disposition, hardy, and capital feeders, producing most excellent beef. Some strains of blood produce milkers of a high order, the milk being of slightly more than average quality. At Smithfield, in 1905, steers approximately two years old weighed from 10½ to 12 cwts., while those just under three years varied from 13 to 15½ cwts. alive. Heifers from two years four months to two years ten months vary from 11 to 15 cwts.

Welsh Cattle. Similar as a group, Welsh cattle [page 432] are more or less divided into local varieties. As a rule they are black; in many cases very large in size, but plain in form and wanting in compactness and quality on the best parts of the carcass. The breed is, however, gradually improving by careful selection. The Welsh are long-horned, somewhat coarse, and slow feeders, although large numbers of steers—generally known as "runts"—are brought into England for grazing and fattening purposes. Some strains of blood produce cows of good milking character. Steers approximately two years old will reach 11½ to 14 cwts., while those just under three years old vary from 13½ to 18¾ cwts., a figure reached by a steer at Smithfield, in 1905, aged two years eleven months, the champion of the breed at the same exhibition reaching 16½ cwts. at two years ten and a half months. The heifers vary from 11½ to 16¾ cwts. at two years and three years respectively.

Among the local varieties are the Pembrokes, or South Welsh cattle, some of which are coloured, or black and white; the Castle Martins, and the Glamorgans, which are black and white, or red.

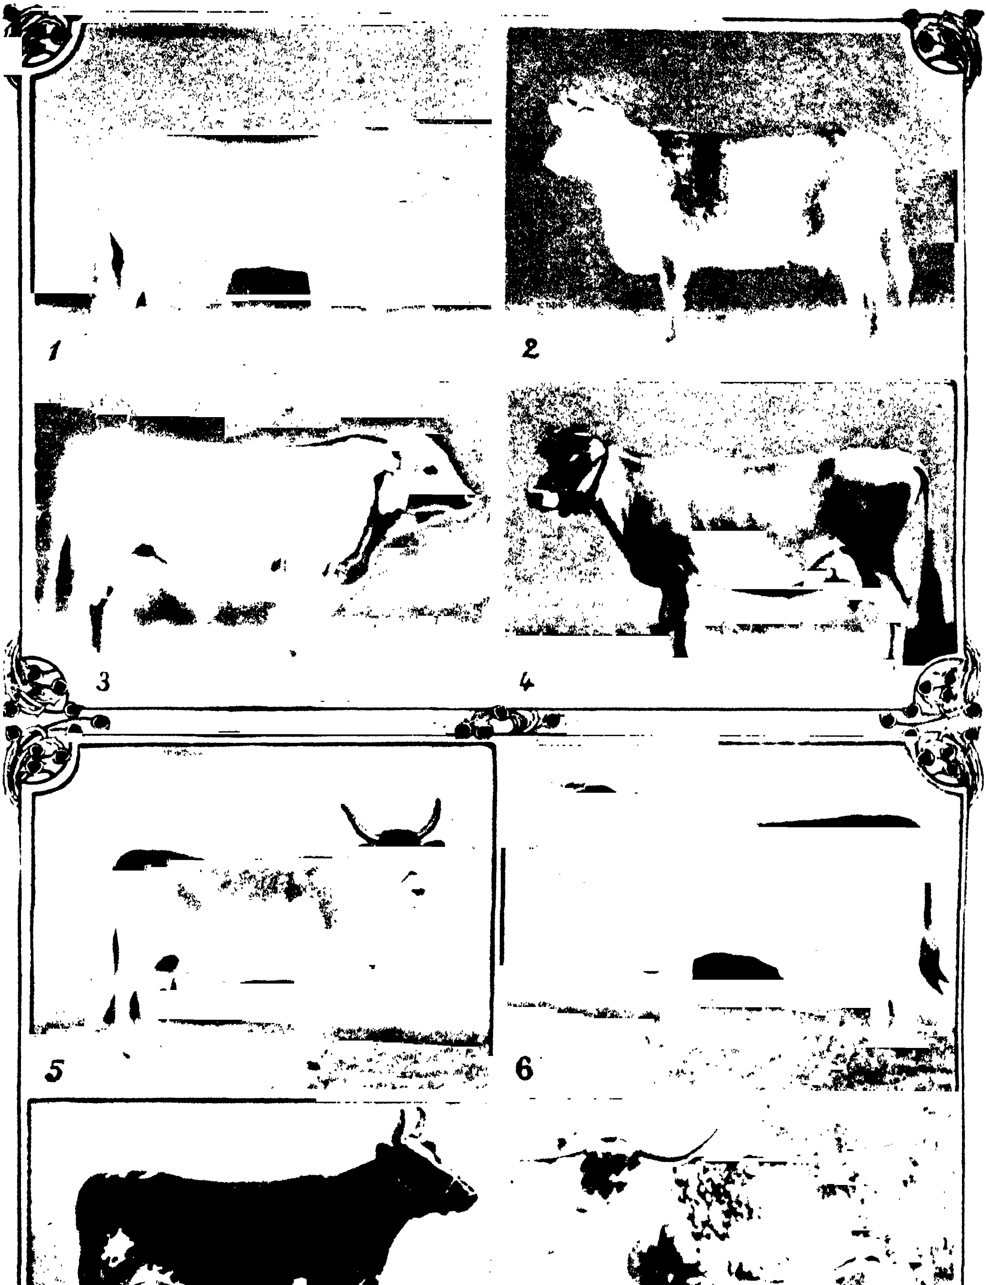
The Aberdeen Angus. The well-known Scottish cattle, the Aberdeen Angus [page 432], are among the choicest of British varieties, frequently gaining the championship at the fat stock shows of the country. They are excelled in form and quality by no known breed, producing the best of beef, but they are poor milkers. The Aberdeens, which are black and hornless, are known as "Doddies." They are extremely symmetrical, with straight top and bottom lines, well-formed quarters, and great depth and girth round the heart. When used for crossing, they immensely improve the stock produced, as well by their quality as by their hardiness. The champion at Smithfield in 1905 was an Aberdeen heifer, weighing 16¼ cwts. at two years ten and three-quarter months. Steers just under two varied in weight from 11¼ to 13 cwts., while steers just under three varied from 15¼ to 17 cwts., and heifers between two and a half and three years old from 12 to 16½ cwts. alive.

The Galloway Cattle. Closely resembling the Aberdeens, being black and polled, the Galloway cattle are coarser in quality and coat, while they are less symmetrically built. They are very hardy, well adapted—in part owing to their longer and warmer coat—to exposure, but they are poor milkers, although making excellent crosses with the Shorthorn, producing the blue-grey cattle so favoured by breeders of stock intended for the butcher. The champion Galloway heifer at Smithfield in 1905 weighed 13¾ cwts. at two years eleven and a quarter months old; steers just under two years reached from 10 to 14 cwts., while those under three reached from 11½ to 15 cwts. alive.

West Highland Cattle. The most picturesque of any breed are the West Highland cattle [page 432]. They possess large-spread horns, long, shaggy coats of curious shades of colour, which, apart from the blacks, which predominate, include red, yellow, dun, and brindled. They are extremely hardy, and used to exposure, but they mature slowly, although they produce beef of the highest class. They stand low on the legs, but are square, rather compact, and are fancied by many landowners and well-to-do farmers, who bring them from Scotland for grazing in parks and on good feeding pastures. The champion heifer at Smithfield in 1905 weighed 14 cwts. at three years eight months old. Steers from two and a half to three years varied from 11½ to 14¾ cwts., while oxen over three years reached 17¾ cwts. alive.

Ayrshires. The Ayrshire breed, the famous cheesemaker of the West of Scotland, is an animal of medium size and varied colour—brown, red, and black, usually patched upon a white ground. It is of an active and yet gentle disposition, and essentially a dairy breed, although the steers at two years old reach 10 cwts. The Ayrshire possesses prominent horns, which grow wide apart, upwards and outwards. The body is wedge-shaped, the front especially fine, the head long, and the udder broad, lengthy, and flat, but the teats are small. This breed is more fully described in Dairy Farming.

Jersey, Guernsey, and Dexter. Being essentially milking breeds, the Jersey, Guernsey [page 431], and Dexter [page 256] are cattle also described in the section on Dairying. In neither case are the steers or the cows, when barren, profitable as butcher's beasts. Both Dexters and Kerries, however, are occasionally crossed with a beef producing variety, and with better results than are obtained when either are kept pure. These results are, nevertheless, much inferior to those which are achieved by breeding from the recognised beef producing varieties.



TYPICAL BREEDS OF BRITISH CATTLE
1. Devon Bull 2. Shorthorn Cow 3. Hereford Bull 4. Jersey Cow 5. Kerry Cow 6. Sussex Bull
7. Ayrshire Cow 8. Longhorn Heifer

Shetland. The Shetland cattle are tiny, shaggy-coated cattle, of varied colours, useful under the conditions in which they are kept for the production of milk and meat, but neither can be regarded as economical stock worthy of recommendation outside the limits of their native home. Great improvement, however, might be effected by the employment of suitable, selected bulls.

Feeding Cattle. Although the principles of feeding are separately discussed in a later lesson, brief reference may here be made to the practice of feeding cattle. Cattle are kept for the production of milk or meat, or both. It is essential, therefore, to supply food in such quantities, and at such times, as will best promote a successful result. The food chiefly employed for fattening purposes are linseed cake, to which a small proportion of cotton cake is sometimes added, maizemeal, barleymeal, turnips and mangels, with chopped hay or straw, or both. Fatting cattle are frequently fed side by side from a manger, or in specially constructed boxes, the floor of which is daily littered, until the manure is collected to such an extent that it becomes essential to remove it. This manure is of higher value than any produced on the farm. In all cases, cattle need protection; exposure to cold winds and rain being followed by slight decreases in weight, or by the consumption of increased quantities of food. Cattle are frequently fed for the butcher on summer and autumn pastures, receiving daily rations in the fields. The result, however, depends much upon the pastures, some of which produce richer and more abundant herbage than others, and are known as being capable of fattening a bullock. It is a common practice either to bring in stock from grass, or to purchase a given number of head year after year for stall feeding, to be sold during the winter months, the Christmas season being often selected. The success of the feeder depends much upon the class of cattle which he purchases or breeds. Crosses with the Shorthorns, Hereford, Devon, Aberdeen, Galloway, Red Poll, Sussex, or pure-bred animals of these varieties, make the best and most profitable beef. The artificial food required, such as cake, should be purchased during the summer, when prices are low, and supplied in weighed quantities with the chaff and roots, which should be sliced or pulped. Cattle which thrive best are those which are docile, contented, chewing their cud in the fields, and stretching and licking themselves when they rise. Unthrifty cattle are easily recognised by their staring coats, their uncomfortable and unthrifty appearance, their distended abdomens, and especially by the fact that after a few weeks of good feeding they gain insufficient weight to pay for the cost of their food. For these reasons, the weighbridge is a valuable adjunct to the farm.

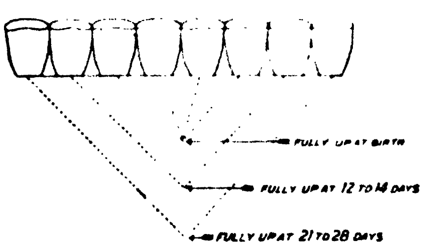
Breeding and Calving. Cattle of the two sexes are variably described at different ages. The male calf is a bull calf, becoming a bullock, stirk, or steer after castration. After reaching twelve months, he is known as a yearling bull, steer, or bullock; after reaching two years, he is a two-year-old, and after reaching three years, he becomes a three-year-old steer, bullock, or ox, the last-named being the more appropriate term. A female at birth is a cow-calf, heifer-calf, or, as in Scotland, a quey-calf. Having reached twelve months, she becomes a one-year-old heifer or quey; on attaining two years she is termed a two-year-old heifer or quey; while at three years old she is a three-year-old heifer or quey, unless she has had a calf, when the term, applied in accordance with the locality, is cow or heifer with first calf. A "maiden" heifer is a heifer which, being adult, has not been crossed by the male. A cow which is in-calf, is known as an "in-calfer," while a cow which, having borne calves, is neither in-calf nor in milk, is a "barrener." When twin calves are born, one of each sex, the female is known as a "free-martin."

A cow usually comes in season every three weeks until she is in-calf There are, however, occasional exceptions. When she is near calving, the udder gradually increases in size, extending to the full when the date has been closely reached. The vent, too, swells, especially when close to parturition. Fleshy cows, or cows which are suspected of a leaning to parturient fever, or "drop," are better placed upon short commons—such as scanty pastures—for a few weeks before calving. In some cases it is advisable to drench these cattle with Epsom salts two or three times during the last few days. When a cow is about to calve—a condition which cannot be mistaken—she should be taken to a box ready prepared for her reception, the floors and walls having been purified and the former strewn with clean wheat or oat straw. She should not be tied up, nor assisted until it is recognised that help is needed. Should she be unable to expel the calf, a stout cord may be passed around its legs just above the feet, and gently yet firmly pulled each time the cow gives a throe. This plan is usually successful. If it is not, the help of a thoroughly experienced veterinarian should be called in. After calving, the dam and her calf should be left alone. The mother will lick her calf, and subsequently turn to a warm bran mash, which may be supplied to strengthen her. The attendant, however, should watch for the expulsion of the "placenta," or cleansing, which some animals have a habit of eating.

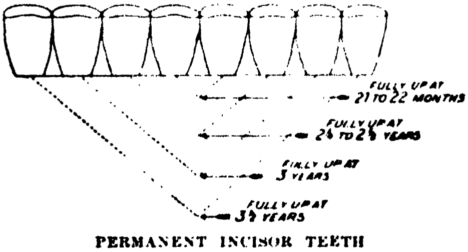
Feeding Calves. Although there should be no coddling, the newly-calved cow may be protected with a rug during cold or draughty weather. The calf should be allowed to take the first milk, known as the "beatings," or colostrum, which possesses a natural and beneficial action. Whether a calf should be allowed to suck its dam until weaning is within the province of the owner to determine. We would, however, point out that this is the most extravagant method of rearing stock. Where calves are fed for veal, a single heavy milking cow may rear four or five calves in succession. When rearing for stock, a deep milker will sometimes rear two on the udder. A better plan, however, is to wean a calf at birth, and teach it to drink. The quantity of milk supplied may then be accurately determined, and the cost of rearing ascertained.

A newly-born calf will consume at three meals daily at regular and fixed hours three or four quarts of milk, according to its size and vigour. Feeding should always be sufficiently abundant, and the calf flesh never lost. Where a calf is fed from the pail, the milk may be increased from week to week for a month; the new milk may then be gradually diminished and replaced by sweet separated or skimmed milk, a small quantity of cod-liver oil (2 oz. per gallon) being mixed with the milk at each meal to provide for the loss of fat thus sustained. Many feeders, however, prefer to mix cooked linseed meal or linseed cake dust, or one of the various patent calf-meals, with the mixed milk, increasing both from time to time until the calf is weaned. In the several sets of experiments on the farm of the Yorkshire College the most economical results were achieved by feeding calves, which were subsequently sold fat to the butcher, upon milk fortified with cod-liver oil in the manner suggested. The oil is practically equivalent in feeding value to the fat of milk, while its cost averages 6d. per lb., or less than half the value of butter-fat.

To return to the cow. While still in the box she may receive a couple of warm bran mashes daily for two or three days, being also supplied with sweet hay and lukewarm water. She should, however, be gradually placed upon the rations which are supplied to the milking cattle in general preparatory to returning her to the herd. Unless the weather is severe, she may be turned out on a genial morning for a few hours, and subsequently for a longer period, being fit within a week to join her neighbours.



TEMPORARY INCISOR TEETH



PERMANENT INCISOR TEETH

Bulls. Although there are breeders who put precocious heifers to the bull at the age of eighteen months, twenty-one months is sufficiently early. The selection of the bull is of the highest importance for he represents, from the breeding point of view, more than half the herd. While each calf inherits certain characteristics from its dam, every calf in the herd inherits those of the bull employed. If the calves are bred for milk production, the bull, like the cow, should be of a heavy milking strain; if for beef, both sire and dam should come of a strain which produces stock of high quality and rapid feeding power. The cow carries her calf from 275 to 280 days—sometimes slightly longer in the case of bull-calves. The calf, which may be castrated at from four to eight weeks if in good and vigorous health, should be weaned at from five to six months. Preparatory to this event, however, it should have been accustomed, by the gradual introduction of these foods, to eat hay, which should be of the best, and rations composed of hay-chaff, chopped roots, linseed cake dust or meal, and occasionally crushed oats. It is uneconomical to turn out spring calves on to pasture land during their first year; good feeding on hand-prepared rations is followed by much better results. Cows used for breeding should never be fat, nor should they, under any circumstances, be allowed to come into contact with cows which have aborted or "cast" a calf. Abortion (which is contagious) is the greatest scourge on the stock farm. This question, however, is referred to in Dairy Farming.

Indications of Age. The age of cattle is chiefly determined by the teeth, but the horn and the general appearance are indications after a cow has passed her prime. Although the rule is by no means invariable, a somewhat imperfect ring is formed on the horn after the birth of every calf, and the horn which is heavily ringed is thus indicative of age. Cattle have 32 teeth, eight being incisors, all of which are in the lower jaw. The centre pair of permanent incisors are up at about twenty-two months; a second pair, those right and left of the centrals, at thirty months; a third pair, right and left of these at three years; and the outside, or corner pair, at three and a half years. In some instances, especially where grazing is hard or the food coarse, these teeth may appear earlier. The remaining teeth are molars, six being provided on each side of each jaw. It is generally assumed that a butcher's carcase weighs four-sevenths of the live animal; in other words, a live bullock weighing a given number of stones of 14 lb., weighs, in the carcase—*i.e.*, deprived of all offal—about the same number of stones of 8 lb. But this does not hold good in well-fatted stock. For example, the champion cross-bred heifer at Smithfield in 1905 weighed 1,247 lb., alive and 812 lb. dead. Thus the butchers carcase weighed about two-thirds, or 66 per cent., of the live animal. Much, however, depends upon the breed and the extent to which the animal has been fattened. Some breeds feed more rapidly than others, and make a larger daily gain in weight from birth to slaughter. The heaviest weights are attained by Shorthorn, Hereford, Welsh, and Sussex cattle, among the pure breeds, and by cross breeds, the last-named being quite equal in this respect to the beef varieties up to three years old. As age increases, the proportion of daily gain

in live weight diminishes. Thus, a Shorthorn steer may gain 2 lb., or slightly more, daily, up to two years old. At the age of three the daily gain will have diminished to 1·6 or 1·7 lb., falling again in the succeeding year. Heifers make slightly smaller gains during the same periods than steers. The highest daily gains are made by Shorthorn, Aberdeen, Hereford, Sussex, Welsh, and cross-bred cattle; and the smallest, amongst the leading varieties of beef-producing stock, by Galloways, Red Polls, Devons, and West Highlanders.

The following figures, which we have arranged on the basis of the averages of Mr. Charles Macdonald, of the "Field," give the average weights of steers and heifers for the year 1905 at our greatest fat cattle show (Smithfield), together with the average daily gains which they have made in the three years from birth. The figures are most instructive, and will enable the student of British live-stock to learn of what each breed is capable, and how far it is possible, by the acquisition of similar weights at similar ages, to realise a profit on the feeding as well as in the breeding of cattle.

As producers of milk, butter, and cheese, the non-pedigreed or dairy Shorthorn stands first among the beef producing varieties, followed by the Devon and the Red Poll. The richest milk is produced by the South Devon, but among the Shorthorns named there are many individual cattle which produce milk equal to that produced by the cattle of the Channel Islands—the Jerseys and Guernseys—these breeds being the best of all for butter production. For cheese-making purposes no breeds are superior to the dairy Shorthorn and the Ayrshire. The Hereford, the Sussex, the Aberdeen, the Galloway, and the West Highlander may be excluded altogether from milk, butter, or cheese-producing stock.

THE MIDDLE AGES

The Development of Christianity. The Birth of States. England under Seven Monarchies. The Danes. Mahomet and his Teaching

Continued from page 2079

By JUSTIN McCARTHY

OUR course now brings us to the history of those centuries known as the Middle Ages. The interval of time thus described comprehends the period between the decline of one form of civilisation and the coming into distinct operation of another. The two events which mark most conspicuously the opening and close of that interval are the removal from Rome of the seat of the Roman Empire and the capture of Constantinople by the Ottoman Turks.

Christianity in Europe. In the meantime many of the peoples regarded by the Romans as barbaric, some of whom had kept them in constant warlike movement by their reprisals and invasions, had been growing into powerful and more or less civilised States.

Formed for the most part on the foundation of common nationality, these States had been growing into a civilisation of their own. Among these were the kingdoms of Gaul and Spain, the Saxon kingdoms in England, the Franks, the Germans, the Danes, the Saracens, the Hungarians, and the Moors. Most of these races were European and Christian, but some of them, as their names indicate, came from the East and had not yet accepted the light of Christianity.

During this period the Christian religion had established its central seat in Rome. The conversion of Constantine to Christianity had contributed emphatically towards the recognition of Rome as the home of the Papal authority, and the Papal authority represented for many centuries the Christian religion. The Popes exercised much political and territorial influence even while the Roman Empire still claimed supreme authority from its new seat in Constantinople.

The Barbaric Races. It soon became evident that some of the races which the Rome of the Emperors had persisted in regarding as barbaric were destined to compete for the leading part in the world's civilisation. England, France, Germany, and Spain were already sending before them the beacon lights of their progress. Some of these peoples were for a time divided among themselves, and even claimed to have a distinction of race which they strove to maintain; but their gradual movement proved to be toward amalgamation and cohesion, prompted and made necessary by the demarcation of the regions in which they lived and about which they often contended, and prompted also by a common national instinct. The outer barbaric world, which was still Pagan, kept up a constant religious strife with the peoples who had accepted Christianity, and the Christians themselves were not slow in their endeavour to spread by arms their power over the barbaric regions.

The Birth of States. The peculiarity of this period of the world's growth was the fact that the wars were mainly carried on with the object of spreading a religious faith or resisting its advance. The Huns, the Visigoths, the Vandals, and other powerful races were spreading their influence widely over Europe. Alaric and his Visigoths captured Rome in the early part of the fifth century, and Attila and his Huns overran Italy and a great part of France. These invasions, while they destroyed much, did not succeed in creating anything, and the real history of the Middle Ages was made for the most part by the European races who were striving to form themselves into separate and cohesive States. The Gauls or French, the Germans, and the Saxons, to whom the kingdom of Great Britain owes its distinctive growth, were beginning to settle down into separate States representing different nationalities. The inhabitants of Great Britain had much keen strife among themselves before this could be brought about, and the strife would probably have lasted longer still were it not that the seas separating the island from the European Continent suggested to the islanders thus defended by nature the advantage of forming themselves into one consolidated State.

The Three Races of Britain. Britain was, until the opening of the Middle Ages, peopled by at least three distinct races. These were the Saxons, the Cambrians or inhabitants of Wales, and the Caledonians or inhabitants of Scotland, who were themselves divided into Picts and Scots. The Saxons came originally from the northern part of Germany, and had established themselves by invasion and conquest, and their settlement in England had brought many Scandinavian incursions. Two famous Saxon chiefs, Hengist and Horsa, brothers, are believed to have led the first band of Saxon invaders to Britain. According to historical record, these brothers were invited by Vortigern, a British prince, to come to Britain to help him against the Picts or Scots who were harassing him by frequent invasions. They readily accepted the invitation, and are said to have become allied with him in another sense by his marriage with Rowena, the daughter of Hengist. The allies succeeded for a time in defeating the Picts and were given the isle of Thanet as a reward. The alliance did not last long, for Hengist and Horsa afterwards turned against Vortigern and were defeated. Horsa was killed in this encounter, but Hengist is said to have remained in possession of Thanet and to have become ruler of the whole region which we now know as the county of Kent. He bore for some time before his death the title of King of Kent.

Seven Monarchies in England. As usually happens under such conditions, the Saxon settlers or invaders were disposed to enlarge as far as possible the region of their settlements and to maintain a perpetual dominion over it. By them was founded the kingdom of Sussex or South Saxons, that of Wessex or West Saxons, and that of Essex or East Saxons. Another race, the Angles, founded kingdoms in Northumberland, on the eastern British coast, and there were no less than seven separate monarchies in England at one time. These were described by historians as the Anglo-Saxon heptarchy and gradually became blended into one united State. The Saxons were the most widely spread and most enduring, and to them Englishmen mainly owe their language except for that very considerable part of it which is taken from the languages of Greece and Rome.

The Franks made for themselves a place of the highest importance in history. They were a people of Germanic origin and were a sort of federation of Germanic tribes between the Rhine and the Hartz Mountains, while the Alemanni occupied the upper banks of the river. The original meaning of the word Frank appears to have been "free man," and the name was given to those German combinations just mentioned, which undertook the invasion of many other parts of Germany, and overran a great part of Gaul. The country of the Gauls, or Gallia, as it was called in classic days, comprised the whole of France and Belgium. The Gauls had made themselves conspicuous during the existence of the Roman Empire, and after the fall of that Empire they succeeded in establishing a kingdom in France, and France succeeded through many tumultuous centuries of war in establishing herself as one of the recognised nationalities and recognised Powers of Europe. During these years the Germans, too, were forming themselves into a distinct nationality and Power.

Races in Search of Homes. The Northmen—Danes—made a temporary settlement in England, and it would seem to one who glances over the history of those centuries as if the people of Europe had not yet decided where their homes ought to be, or even as to the regions from which they had descended.

The various tribes and races would appear to have been each in quest of its ancestral and actual home, and to have conducted its invading enterprises with the hope that, by penetrating successively into each territory, it must at last reach that particular land from which its forefathers had come. It is certain that some of these enterprises were not undertaken with the mere desire to plunder weaker tribes, or even with the ambition for territorial conquest, but that many of the invading races were inflamed with something of a half poetic, half religious passion for a re-discovery of their ancestral home and a permanent settlement in it. Such a feeling might be explained in great measure by the fact that so many of those peoples had in their early days been driven out of their own country by the invasion of conquering races, or had themselves taken possession of regions foreign to them, and had had to maintain that possession by generations of war and incessant strife, finding themselves at last becoming less and less suited to the climate and the other conditions of the territory which their ancestors had captured.

Rise of European Powers. There became thus gradually established in Europe several distinct nationalities or States recognising themselves as such and demanding a like recognition from their neighbours. These States were England, France, Spain, Italy, Germany, Russia and Turkey. There were also other distinct nationalities such as the Scandinavian peoples in the North of Europe, the Hungarians, and the Greeks. The Ottomans remained during all manner of changes, and were then, as they still are, an Oriental settlement on the soil of Europe. The history of Ireland had for a long time little or no association with that of England, and the earliest records of Ireland's story show that the Irish always claimed for themselves an origin entirely different from that of the neighbouring and larger island. We shall deal with the history of these various nationalities as we follow their course. For the present our object is to show how the populations which had grown up in Europe, or had come into Europe by invasion, began to form themselves into separate States.

So far as the Eastern world was concerned, the great wall of separation between Europe and the Oriental peoples, even between the rest of Europe and the one Oriental people holding position as a European State, was raised by the spreading influence of Christianity. Already the European world was divided by religious faith into Christians, Jews, and Mohammedans—the latest traces of Paganism may be said to have disappeared. The religious difference between the Christians and the Jews did not tend to prevent the recognition of a common citizenship in many or most communities. The Jewish converts to Christianity were daily increasing, while no conversion of Christians to Judaism showed itself anywhere to any extent worth noting. Thus the growing kingdoms and empires of Europe proclaimed themselves Christian, and there was even already a degree of vitality, and an amount of solidity in them, which marked them out distinctly as enduring component parts of the world's system.

The Great Cities. Some of the great centres of modern civilisation were already beginning to claim recognition. London, the capital of the British Empire, had been occupied by the Romans, and is described by Tacitus in the first century as a prosperous trading city. He writes of it as Londineum, a name which is understood to have been not Roman but Celtic, and to have meant the gate or fortress of a lake or river. Paris was called Lutetia while the Roman Empire still prevailed, and during the time of Julius Cæsar that name applied to the rising town or settlement on the Seine of the Parisii, a Gallic tribe conquered by the Romans. Lutetia in the fourth century A.D. became known as Parisia or Paris, and two centuries later under Clovis it became the capital of the whole country and a Royal residence. Many of the other European capitals came into established recognition at a later date. But the division of Europe into States with recognised frontiers and limitations was almost entirely the work of the Middle Ages. Although many modifications, separations, and reuniting of populations have since taken place, yet the boundary lines on the whole seem to have been traced out and settled during that eventful period. Feudalism had its beginning in the Middle Ages, and so had that system of religious chivalry to which we owe the Crusades.

Eastern Nations and Christianity. The spread of Christianity and the growth of so many European States roused the Eastern world into anxiety and alarm as to the growth of this new power which Eastern kingdoms were already beginning to regard as a danger threatening their own existence. The Roman Empire had already invaded the East and settled itself in Constantinople. The Eastern nations naturally failed to understand that this change foreboded the decay and not the increase of Rome's power, and the establishment of the Roman capital in a region bordering so closely upon Asia was regarded as a warning that a coming invasion of the East, not merely by a conquering European race but by a religion which had already conquered Europe, was one of the events of the near future. The dread of such a prodigy led the minds of Arabians and of other Eastern races to doubt whether the faith which they and all their ancestors had professed was that securely established form of creed which the Divine Overruling Power had destined to be eternal. It was a time of revolution, and we all know that such a period is ever sure to bring to the front some daring and self-inspired propounders of new principles and leaders of new enterprises. Arabia was especially a country in which such phenomena might be looked for. Its people were intelligent and thoughtful, and they had had much intercourse with Europeans forced upon them by frequent visits of travellers and even of invaders from the Western world. They were not wrapt up wholly in that reverence for ancestral and for settled forms which was a characteristic of other Eastern races—the Chinese, for instance. The course of events illustrates our meaning.

Arabia. One of the greatest changes made in the world's history during the period following the fall of the Roman Empire had its origin and its workings in Arabia. The country which was destined to play so important a part in history was, during the greater days of the Roman Empire, but vaguely known to civilisation, and was assumed to be little better than a vast desert. It is an immense peninsula which spreads northwards into Asia. The geographers of the Roman world divided it into three parts: Arabia Petraea, Arabia Deserta, and Arabia Felix. Its earliest religion, so far as it can be traced, was a sort of idolatry, a worship of vague divinities springing from the almost universal belief in some supernatural ruling power, a belief congenial with the Arabian mind, which was naturally poetic and could not limit itself to an acceptance of the material world which it saw every day, but had to create for itself some form of faith independent of and above the world around. More lately some of the Arab peoples had been touched by the spirit of Christianity, while others had been attracted by the teaching of the Jews who were then penetrating the country from all sides, and large masses of the population had gone no farther in their religious belief than to acknowledge the worship of Allah, whom they regarded as the Supreme Being, and with whose worship they associated many forms of idolatry.

Mahomet. There arose at this time the man who was destined to found a faith and a powerful dominion, both of which were to exercise a long-enduring influence throughout the whole of the Eastern world. This man was Mohammed, or, as he is now usually called by English writers, Mahomet. Mahomet was born in Mecca about the year 570, A.D., and was the son of a merchant who was very poor, although belonging to one of the powerful tribes into which the country was divided. His father died very soon after Mahomet's birth, and his mother passed away while he was still a child. The little boy was taken in charge by an uncle, and obtained his living for a while mainly by tending sheep. Then he took to camel driving, and travelled largely through Syria. He proved to be a young man of remarkable intelligence, and his mind became filled with a fixed idea—the rescue of the faith of Abraham from what he believed to be its perversion by the Jews. To this purpose it became his unconquerable ambition to give himself wholly up. Fortune is proverbially said to favour the brave, and fortune favoured Mahomet at this critical moment in his career. A rich widow named Khadijah, some twenty years older than he, and destined to be known to all history because of him, fell in love with the young man and left him free to give up the work of making a living, and to follow out his own path of inquiry and aspiration. His wife is believed to have enjoyed his full confidence in the great project which he had now set out for himself, and to have helped him by her counsels and her encouragement. Then came the dreams of the self-absorbed fanatic, a sincere fanatic and a dreamer who reverenced his dreams as realities.

The Koran. Mahomet made known to his wife and to his confidential friends that he had received from the Divine Power, through the angel Gabriel, a message embodying the contents of a book which was to be the religious instructor of the human race. The book was called Alkoran, or the Koran, "Al" being the Arabian version of the article "the," and Koran signifying emphatically a book that must be read. Mahomet described the religion, which was to be authorised by this book, as Islam, a word signifying obedience to the Divine commands. There must have been something inspiring in the nature and the character of the man which won on those who listened to him, for from the very first his wife and his friends regarded him as one endowed with a mission to proclaim a new doctrine. His believers and followers increased day by day, and before long seemed to the State authorities to be a danger to the faith of the people and even to the safety of the country. Mahomet soon found that his life was in peril, and he fled to Yathreb, afterwards known as Medina. The time of his flight, the year 622, dates among the Mussulmans as the Hejira—the flight of the Prophet from the region which would not accept him.

Mahomet communicated the text of the Koran by word of mouth to his followers, and they took down his utterances on palm leaves or on pieces of leather when they could not find better material for their records. Mahomet himself did not write down his revelations, and, indeed, made it his boast that he was absolutely illiterate, and that he was guided by inspiration and not by education. The book was afterwards put into shape, and revised, and modified under the reign of successive Mohammedan caliphs; but in its main purpose it remained unaltered as a code of religious, moral, civil, and even political teaching, suited, as if by instinct, to the character and temperament of the Eastern populations over whom it was to have so large an influence. The teaching of the Koran, when considered in its purely spiritual sense, may be summed up in the dogma, "There is no God but God, and Mahomet is His Prophet." The book differs essentially from the creeds prevailing in the days of Greece and Rome and before the Christian era, for it shut out altogether any recognition of the existence of a variety of deities, each presiding over and directing some part of man's nature and life.

Mahomet's Teaching. Mahomet preached as his doctrine the immortality of the soul, the resurrection of the body, and the rewards and punishments allotted in the future life. He admitted that Christ had worked miracles and did not claim for himself any such power, but he maintained that he bore the latest message from Heaven, and that humanity must accept and obey his teachings. The Koran condemns most of the acts and practices which the Bible regards as criminal; and it is very strict and minute as to prayers, fasts, and sacred days and the annual pilgrimage to Mecca, which Mahomet had appointed as the central home of the new worship. He displayed a certain degree of toleration towards Christians and Jews, and while advising his people not to enter into marriage relations with those who professed the creed of Christ or that of Abraham, he declared it not lawful to make war upon them unless when they themselves had begun the attack and thus made resistance needful. But as regards all races who did not profess to follow the teachings of Christ or those of Abraham, he held that it was the duty and the right of all true believers to pursue them and to crush them, unless they would accept and practise the doctrines taught by the Koran.

Ruler of Arabia. By this time Mahomet had grown to be a great ruler and a great political power. He had for many years been merely an itinerant preacher of his new faith; he had lost his devoted wife, and, having spent much of the money she had brought him on the spread of his religious teachings, had been more than once reduced to poverty. But Mahomet was not a man to be turned from the course he had marked out for himself. He continued to increase the number of his proselytes, and struggled fiercely at the head of his followers against all sects which opposed him; he became a great military chief, and he captured Mecca. He was recognised, in fact, not only as the Prophet, but as the ruler of Arabia. His career brought about one of the greatest revolutions known to history, and for a time his was the one absolutely commanding figure among Eastern peoples who had been converted to his doctrine. It may seem to European students hard to understand how a man so little favoured in any sense by fortune at the opening of his career should have created for himself so wide-spreading and so enduring a domination. He was not born to greatness, he does not seem to have had the intellectual gifts of a Julius Cæsar, and, although he claimed to be a religious prophet, he did not conquer his world by religious teaching alone, but had recourse to the warlike arts of the ordinary conqueror—arts for which he had had no special training. His career is not to be explained by any of the explanations which serve to illustrate the careers of others who made themselves masters of peoples and founded new systems of government. We have to take him as we find him, and to regard his success as one of the most marvellous prodigies of the Middle Ages. During his last pilgrimage to Mecca he proclaimed on Mount Ararat the ceremonials of the pilgrimage as they were to be for all future years.

Mahomet's Death. His death was peaceful, and came to pass shortly after this last pilgrimage. He fell ill soon after his return to his home, and never recovered. So long as his sinking strength would allow him, he took part in the public prayers. He died early in the June of 632. His character unquestionably had many great defects. He was sensuous in peace, unrelenting in war, and unsparing in his punishment of those who offended against him. But it is only fair to say that these were defects peculiarly characteristic of the times he lived in and the country in which he was brought up; and that the new faith he sent forth did not even profess to be a creed which preached and pleaded for purity of private life and mercy towards conquered enemies. It is impossible not to feel that there must have been an intense sincerity in his nature, that he must have been convinced that he was charged with a sacred mission, and that in following out his career he was not governed by any passion for personal aggrandisement or by the selfish desire to become a ruler of men.

SYSTEMS OF SUPPLY

Direct and Indirect Supply. Two-wire and Three-wire Systems. Motor Generators and Converters. Feeders and Boosters

By Professor SILVANUS P. THOMPSON

ELECTRIC energy is supplied to the public on several different systems. Since the lamps and motors which are adapted to work on one of these systems are not always suitable to work on another system, it is important that the peculiarities and properties of the different systems should be understood. Also, it is necessary that the meanings of the terms used in describing their arrangements should be made quite clear. The term *system* is itself used in two different ways to mean (1) in general the collection of machinery and distributing mains that supply the current, as, for example, when one says that the Hampstead system supplies 60,000 lamps; (2) in a technical sense to distinguish between one electrical method of supply and another method, as when one speaks of a *three-wire* system or of a *high-voltage* system. It is in this technical sense that we use it in this section.

Methods of Supply. All methods of supply may be divided under two headings—namely, *direct* and *indirect*. In the former, the current is supplied to the consumer at the same voltage at which it is generated at the station, there being a *direct* electrical connection of metallic wires between the two. The indirect methods are used when the supply area becomes so large that it is no longer economical to generate at the same voltage at which the current is supplied to the lamps and motors in the consumers' houses. Such methods of supply divide the system up into two parts—namely, a high-voltage part used for transmitting the electrical energy, and a low-voltage part for distributing it. So the supply of current is *indirect* in that there is no direct electrical connection between the generators and the lamps, motors, or other devices for utilising the supply.

Classification. Classifying the various systems under these two main headings, we have the following table:

DIRECT METHODS	INDIRECT METHODS
Series Distribution	Transformers to step down at sub-stations
Parallel Distribution— (a) Two-wire (b) Three-wire	Transformers at generating station to step up, and at sub-stations to step down
Series-parallel Distribution	Motor-generators in sub-stations
	Converters in sub-stations

Series Distribution. An early way of distributing current to arc lamps was to join them all in series, as indicated diagrammatically in 157. In such a case the same current goes through all the lamps, and as it must be maintained of invariable strength, the system is also called the *constant-current* system. When this system was in use, one dynamo was designed to give the current to, say, 40 lamps in one series. As each needed about 10 amperes at 50 volts, the arc-lighting dynamo for that circuit was required to generate a 10-ampere current at 2,000 volts. In order to extinguish any one lamp, it had to be short circuited, otherwise the rest of the lamps in that series would have gone out also. Had these 40 arc lamps been arranged in parallel the dynamo would have had to work at about 60 volts—allowing a 10-volt drop—and would have had to furnish 400 amperes to the mains, which must therefore have been of very thick copper; whereas, if joined in series, the wire need only be thick enough to carry 10 amperes. Hence the series system lent itself to cases where are lamps were wanted at long distances apart, with overhead wires. But where there is a regular distributing supply in a town, it is not worth while to put up a separate series system for lighting the streets.

Parallel Distribution. This is shown in diagram in 158. The lamps are connected individually across the mains by wires which connect across from positive to negative, being thus electrically in *parallel* with one another. The fraction of current which passes through any lamp passes through that one only, and then goes to the return main. Hence the two distributing mains have to be thick enough to carry the sum of all the separate small currents going to the individual lamps. Suppose that in a building wired on this plan there are eight arc lamps taking 10 amperes each, 400 glow lamps of 16-candle power taking 0·5 amperes each, and 50 other glow lamps of 32-candle power taking 1 ampere each, then the total current will be $(8 \times 10) + (400 \times 0{\cdot}5) + (50 \times 1) = 330$ amperes; and the mains supplying that building must be thick enough to carry that quantity of current.

When this simple arrangement is adopted, it is sometimes described as a *two-wire* system, and as the same voltage is always required on every one of the lamps that are connected to these mains, the dynamos must be designed to supply the mains with an unvarying voltage.

Formerly, the two-wire systems in English towns were supplied as 100 volts, and the lamps were made so as to give their proper brightness at that pressure. In recent years the supply is more often given at 200 volts, and the lamps have to be made with filaments that are both longer and thinner, and are consequently more fragile. At the double voltage they take, of course, only half as much current to give the same light; but they consume, of course, the same number of watts. The advantage is in the saving of the cost of copper in the mains, which may be made, for an equal total energy supplied, of one quarter the weight. Whatever the voltage of the two-wire mains, the method is a *constant voltage* system.

Series Parallel Distribution. Before the makers had found out how to make lamps suitable for 200 volts, a plan of working with 200-volt mains was adopted as shown in 159, in which two 100-volt lamps were joined in series with one another, and connected across the mains. This plan has the disadvantage that if one lamp goes out the other goes out also. It was proposed to remedy this by cross-connecting the rows of lamps with a middle wire (shown dotted in 159); but this is not satisfactory unless the middle wire can itself be kept at an exact intermediate voltage. The plan of putting several lamps in series into each parallel branch across the mains is used in certain cases when the distribution is at a high voltage; for example, on some of the electric railways that are worked at 500 volts it is customary to light the carriages with 100-volt lamps, five of which are connected in series and fed at 500 volts.

Voltage Drop. Whenever current is sent through a long conductor, part of the electromotive force is spent on driving the current through the resistance of that conductor. Hence, in supplying current to lamps through a pair of mains, there will be a voltage drop, and the lamps will receive a voltage lower than that of the generator. The amount of the voltage drop is readily calculated in any given case by applying Ohm's law [page 671], by merely multiplying together the number of ohms of resistance by the number of amperes of current flowing through that resistance. Suppose a current of 80 amperes to be supplied to a house 100 yd. from the dynamo, through a pair of mains made of stranded copper of the size known as 37-18's. These mains—that is, the going main and the return main—will together offer 0·0875 ohms resistance, and when the full current is on through them the drop will be 80 × 0·0875 = 7 volts. If, then, the dynamo were to generate its current at 100 volts, the lamps would get only 93. Or, to give the lamps their proper voltage, the dynamo ought to be so compounded [page 1324] that at full load its electromotive force rises to at least 107 volts. In all distributing and transmission mains voltage drops occur, and must be taken into account in the calculations.

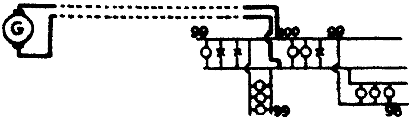
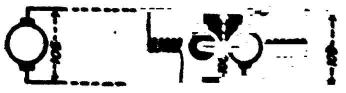
164. FEEDER DIAGRAM



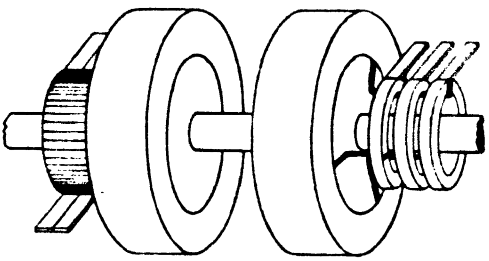
165. FEEDER DIAGRAM



166. DIAGRAM OF BOOSTER

Three-wire System. When lamps at 100 volts were appropriate for use in private houses, the supply companies sought to gain the economic advantage that arises from the use of a double voltage by making the connections shown in 160, where the set of lamps A may represent those in one consumer's house, or in one side of a street, and the set B represent those in another house or in the other side of the street. In this way there is a voltage of 100 only in either A's house or in B's house; yet it is 200 volts between the two outer mains. The disadvantage of such a plan, if this were all, is that the number of lamps which A has alight at one time may not be the same as that which B has alight at the same time; and since the total current going through the two sets is necessarily the same, if A has more lamps going than B has, A's lamps will not get enough current, and will look dull, while B's lamps will get more current than they should, will be over-bright, and will be soon spoiled.

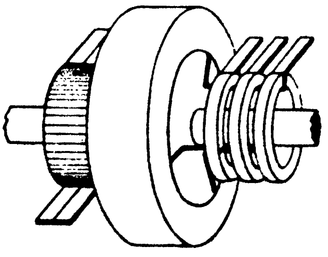
Further, in consequence of the inequality in the number of lamps on the two sides, the central connection, or middle wire, will not be at a voltage midway between the voltages of the two outer mains. In this statement lies the solution of the problem. If we can keep this middle wire at a voltage midway between the voltages of the outer mains every lamp will get its proper voltage, and take its proper current, irrespective of the number that may be alight on each half of the system.



167. DIAGRAM OF MOTOR-GENERATOR

Modes of Balancing. An arrangement to solve this problem is indicated in 161. A battery of accumulators is connected across the outer mains, and the middle wire of the distribution system is connected to the middle of the battery. In laying out an electric lighting scheme on the three-wire plan, the engineer makes a judicious selection of the streets or districts which are to be connected up to one side or other of the middle wire, choosing them so as to ensure as nearly as possible equal demand for current in both halves. Then the amount of *out-of-balance* current (or difference between the amperes demanded on the A side and on the B side) will flow to or from the battery along the middle wire; and if his choice has been judicious, this in-and-out flow will be relatively small. The battery, in fact, has to supply the balance of current between the two sides of the system, and the middle wire may be thinner than either of the outer mains. The battery may be placed either in the generating station or at some convenient spot nearer the centre of the actual points of distribution.

Figs. 162 and 163 show other arrangements of the three-wire system, for the balance between the two sides may be maintained by other means than by batteries. In 162 we have two similar dynamos, which may both be seen on the same engine, and which are connected electrically in series with one another, with the resulting voltages as marked on the diagram. In 163 we have an arrangement which is equivalent to a battery at a distant part of the mains, and which consists of two identical shunt motors, the armatures of which are connected in series with one another across the mains. Their field-magnet coils must be suitably cross-connected. This combination is called a *balancer*. Its action is as follows. Normally, both machines run as motors doing no work, generating back electromotive forces [see page 1593], practically equal to those of the mains. If, however, owing to the consumer's lamps on one side (say, A) of the system being more numerous than those on the other side, the voltage between outer and middle will fall a little at one side and rise a little at the other. Immediately, one of the two motors will automatically begin to work as a motor, and give power to the other one, which then works at a higher electromotive force, and begins to generate current and pump it into the side where the demand for current is greater. It thus preserves the balance, and keeps the middle point at a mean voltage.



168. DIAGRAM OF CONVERTER

Feeders. In a network of cables used for supplying a town from a central power-house, the cables may be considered as of two kinds — namely, (1) *feeding* cables, which go straight from the station to local centres without any intermediate branching; and (2) *distributing* cables, which start where the feeding cables end, and from which are tapped off at many points, wherever necessary to supply another street or a fresh customer, the smaller branch-mains. To minimise the voltage-drop between the power-house and the farthest consumer, the feeding cables are brought to the distribution network at a point selected so as to be as central as possible. This point is quickly made evident by reference to 164 and 165. In these figures the thick lines represent the feeder cables, which in this case are allowed to produce a drop of five volts by the time the feeding points are reached. In 164 the feeders are connected to the nearest end of the local network, and the voltage-drops are indicated, the greatest drop being at the farthest end, where the 100 volts drops to 96. In 165 the feeders are brought to a central point in the local network; and it will be seen that the voltage drop at the distant end of the network is thereby much reduced.

Boosters. In some cases the drop of volts in the feeder cables, shown above as 5 per cent., becomes a serious item. The drop is not the same for all loads, for it is proportional to the current [see Ohm's Law, page 670, etc.], so that in the daytime, or late at night, when very little current is being taken, practically the full voltage of the station (assumed here at 105 volts) is across the distant lamps, which will then burn over-bright; while during the period of full-load in the evening there will be a voltage of 98 or 99 only for these lamps, and they will run dull. Such a wide variation is not desirable, for incandescent lamps are sensitive to changes in the voltage. Hence, there has arisen a practice of compensating the voltage-drop by means of a piece of apparatus known as a *booster*, which is used either at the station or at the network end of the feeders, to raise or "boost-up" the voltage little by little as the feeder becomes loaded. Fig. 166 is a diagram of a booster, and shows that it consists essentially of a shunt-wound motor, M, driving a series-wound generator. The motor, runs at a constant speed, while the current which flows through the armature and field-coils of the generator is the current which is being supplied through the feeder to the network, so that the amount of magnetism in the field-magnets of the generator depends on the current that is being supplied; hence also the voltage added by the generator part is proportional to the load on the feeder. Other methods of exciting the booster are obviously possible.

Indirect Methods of Supply. The first two of the methods noted under this heading at the beginning of this article are used both in continuous current and alternating current working. The necessity for these indirect methods has already been explained, and it is sufficient to mention that they are carried out with continuous currents by the use of motor generators, the motor receiving current at one voltage, and the generator being wound for a different voltage, higher or lower, according to whether we are considering the central or the sub-station end of the transmission line. With alternating current the conversion is much simpler because we can use transformers [page 1657], in which there are no moving parts, and which can, therefore, be installed once and for all in a manhole or in a street pillar and require no further attention.

The third method noted is used on continuous current, as described above, but it and the fourth method are used more particularly in places where alternating current is used for transmission and continuous current for distribution. A motor-generator for this purpose would consist necessarily of an alternating current motor coupled on the same shaft to a continuous current generator of equal capacity, and the electrical energy would be first turned into mechanical energy by the A.C. motor, and then this mechanical energy is converted into electrical energy by the C.C. dynamo. This arrangement is not the most compact, for with alternating currents it is possible to combine the motor and generator in one machine, called a *converter* or *rotatory converter*, thus enabling the efficiency of the transformation to be increased.

Converter. Referring to 59 [page 1106] and to 79 [page 1358], we see two revolving type armatures, the former being used for continuous and the latter for alternating current. Now, both these armatures might have been fitted with a commutator, and would equally well have given continuous current, or, on the other hand, both might have been fitted with slip-rings, and they would have been equally suitable for supplying alternating current, either single or polyphase. From this it is obvious that one of these armatures could be fitted with a commutator at one end and slip-rings at the other. We could then draw both continuous and alternating current from it. Such a dynamo is called a *double-current* machine, and the current which flows in the armature conductors is the sum of the continuous and alternating currents which leave at either side, and the total copper losses in such an armature would be the same as would occur in separate A.C. and C.C. armatures each carrying the same respective currents.

If, however, having got the machine running at the correct speed, we supply current to one side, say, the slip-rings, and draw current from the commutator, we shall have the *converter*, for the alternating current in passing through the machine will have been converted into continuous current, and the current in the armature will now be the difference between the alternating current supplied and the continuous current drawn from the machine. Figs. 167 and 168 show this evolution of the rotatory converter diagrammatically. In 167 we have two similar armatures mounted upon the same shaft, one acting as an alternating current motor, and the other as a continuous current generator. In 168 we have the two armatures superimposed upon one another, with the result that both the copper and iron losses are reduced to about half, and the cost of the converting machine will also be greatly reduced.

Converter Voltages. It is to be noticed, however, that the rotatory converter cannot receive alternating current at the high voltage of transmission. On pages 1324 and 1358 we have given formulæ for calculating the voltages generated in C.C. and A.C. armatures, and, comparing the two, we see that the C.C. and A.C. voltage which will be induced in the same armature is not the same, and for this reason, if we wish to obtain currents from a converter at, say, 500 volts, we have to adjust the voltage at which the alternating current is supplied to about 350—in the case of three-phase working.

Converters versus Motor Generators. As the alternating voltage has to be made suitable to the continuous voltage required on the converter, we see that, for use with high voltage transmission, alternating current transformers are necessary to reduce the voltage from, say, 6,600, the voltage of transmission, to 350, the voltage required for conversion, and their cost and the losses in them have to be reckoned in with those of the converters when making calculations for the whole plant. If motor-generators be used, the high alternating voltage may be used direct on the motor. But here we have two machines, with an extra cost and higher losses than we have with one, so that, taking all things into consideration, it is generally found that of the two types of converting equipment the converter with its necessary step-down transformers is the better.

The general character of rotatory converter armature, compared with the ordinary dynamo armature, is that the commutator and slip-rings are excessively large compared with the size of the core body, because of the larger current they have to carry.

FIRST CLASS CLERKSHIPS

General Conditions of Civil Service Appointments. Details of Emoluments, and Conditions of Entry. The Examinations. Class I. Clerkships

NATIONAL SERVICE
continued from page 2161

By ERNEST A. CARR

Our Conspectus and its Purpose. The schedule appearing on page 2252 summarises for convenient reference the leading features of each general grade of appointment in the national service. It thus affords, as it were, a bird's-eye view of the whole subject that should prove useful to prospective candidates who are uncertain by which of the many avenues of approach they should seek to enter State employment.

In this and succeeding chapters the main outlines furnished by the table will be amplified with full particulars respecting each of the appointments in turn. The educational level of the examinations, for example, will be more exactly defined by a list of subjects and marks. Meantime, the table itself calls for a few words of comment.

First, then, as to the salaries given in Column 5. These are by no means to be regarded as representing the *possibilities* of each class. In almost every instance, ability and good fortune may secure a maximum well in advance of the figures shown. Our aim has been to show, not the utmost salary within the reach of individuals, but the amount which, having regard to the constitution of the staff and the conditions of engagement, may fairly and reasonably be anticipated without special promotion or unusually rapid rise in grade.

A Word of Caution. On this matter of salaries the representations of certain Civil Service "coaches" must be taken with a grain of salt. Anxious, for their own ends, to attract candidates to the service, they contrive, while avoiding any definitely false statement, to convey utterly wrong impressions as to its prospects. Assistantships of Excise, for instance, are announced under the headings £85 to £800. How should the raw novice guess that of an Excise staff numbering some 3,500 members, only a couple of dozen officers are receiving as much as £800 a year? The average prospects of Excise officers are more accurately represented by the figures shown in our schedule.

It should be noted that examinations in this service are dependent on the fluctuating needs of its various departments, and therefore are held for the most part at irregular intervals, as well as for a varying number of appointments. In some instances there may be a year or more between the competitions; but those by which the ranks are mainly recruited occur, as a rule, twice or thrice yearly. Columns 6 and 7 of the table furnish useful indications of the number of vacancies to be expected in each grade, and the severity with which they are contested.

A further feature calling for notice is the classification of posts according as they relate to particular offices or to the general clerical staff. Members of the latter are employed indifferently in all the larger departments. A successful competitor for a Second Division clerkship, for example, may find himself appointed to any one of about 60 Government offices, variously situated in London, Edinburgh, or Dublin, and offering very different duties and prospects. The wishes of each candidate, it is true, are consulted as far as practicable, but those who are lowest on the list necessarily receive the appointments that their better-placed rivals have passed over.

Nationality of Candidates. For posts in the national service it is essential, as already mentioned, that candidates should be "natural-born British subjects." This definition includes any person born in his Majesty's dominions, even though his or her parents may both have been lawful subjects of a foreign state. Concerning naturalised aliens and candidates born abroad, the following announcement is made by the responsible department: "A person born in a foreign country who can prove that his father or his paternal grandfather was born in British dominions is, if he has not expatriated himself under the Naturalisation Act of 1870, admissible as a natural-born British subject to all open competitions which he is in other respects qualified to enter, except those for Student Interpreterships. For these he needs the permission of the Foreign Secretary. Naturalised aliens are admissible to compete for Home Civil Service appointments."

"Wrinkles" for Students. Apart from a few special requirements of the Civil Service Commissioners, to be explained hereafter as occasion arises, the whole range of study requisite for the various examinations is covered by the courses of instruction given in the SELF-EDUCATOR. The consideration of examination subjects need not therefore detain us now. But before passing to a detailed discussion of the several grades of appointment, space may be found for a few general hints—the outcome of personal experience—on preparing for these competitions.

It is essential, in the first place, to realise that they *are* competitions, and that the task awaiting the candidate is not merely to do well in the subjects prescribed, but to do better than the great majority of his rivals. A single mark more or less may mean success or failure, and as the time allowed for Civil Service examination papers is seldom really adequate, the student must acquire by constant practice the habit of expressing himself tersely, pithily, and to the point. In the actual contest this training will enable him to deal with as much of each paper as his knowledge of its subject-matter allows, and thus to secure as many marks for it as possible. Neglect of such a precaution leads candidates into wordy, tedious replies, unfinished papers, and, as a result, a distressing because needless loss of marks.

For the same reason, a speedy, neat, legible hand must be cultivated ; and since handwriting is frequently an examination subject in itself, carrying high marks, the particular style of penmanship preferred by the Commissioners should be adopted. This is a clear, running hand, slightly sloped, and wholly free from flourishes, with rounded curves, small capitals, and short loops and tails to the letters.

The Value of Past Papers. An immense amount of effort is uselessly expended by Civil Service students every year for lack of a perfectly simple precaution. They fail to ascertain the precise scope of the examination for which they are preparing, and consequently either waste precious time over features of their work to which examiners attach no importance, or else discover in the examination room that they have underestimated the knowledge expected of them. Either error might have been avoided by a careful study of the papers set in prior contests of the same nature. Indeed, it is difficult to overestimate the advantages of that course. By a comparison of several sets of old papers the character of the test can be gauged to a nicety, and the work of preparation greatly simplified. The question tests may also be employed for the purpose of "practice examinations"—carried out, as far as possible, under actual conditions, and with special regard for the time officially allotted for each paper. In this way, as in no other, the student can familiarise himself with the trial that awaits him in the examination room. Further, the majority of the sets of questions published by the Commissioners contain tables showing the marks of successful and unsuccessful competitors in each subject, and thus afford a useful measure of the training necessary in order to succeed.

For all these reasons candidates are strongly urged to lay hands on all available papers of recent date for the grade they have in view, and to study them with the greatest care. A list of lately published sets of examination questions showing the price of each, will always be supplied gratis on application to the Civil Service Commission, Burlington Gardens, London, W. Any set required—if in print—may be purchased, either directly or through any bookseller, from the official agents—Messrs. Wyman & Sons, Limited, Fetter Lane, E.C. ; Messrs. Oliver & Boyd, Edinburgh ; and Mr. E. Ponsonby, 116, Grafton Street, Dublin.

CLERKS.—CLASS I.

With the possible exception of diplomatic posts, which are practically restricted to men of good family and social standing, first class clerkships are undoubtedly the most attractive appointments that the national service has to offer. They constitute the upper section of the general clerical staff in the various Government departments, and are characterised by responsible but not arduous duties, assured position, liberal increments, and a certain prospect of at least £800 to £1,000 a year. Nor is this all. Promotions are freely made from their ranks to still more desirable offices, including the highest dignities and most liberal incomes enjoyed by permanent officers of the State.

Salaries Official and Actual. Let us consider, first, the assured value of Class I. appointments in themselves. These vary somewhat in different offices, but are generally classified in three grades, advancement being made from one to the next as vacancies arise. In a few departments—notably the Treasury—the maximum attainable without promotion is as high as £1,200 a year; but with these exceptions the scale of salaries prescribed does not exceed the following :

Third Class, £200, advancing £20 yearly to £500.

Second Class, £600 or £700, by £25 to £800.

First Class, £850 or £900, by £50 to £1,000.

The remuneration for many of the posts offered is fixed on a less liberal basis. Commencing at £150, it rises by £15 yearly to £300, thence by £20 to £500 or more, and afterwards by £25 to £800 or £900.

Owing, however, to the special emoluments and liberal opportunities of promotion enjoyed by these clerks, the above rates by no means represent the real value of Class I. appointments. Many juniors are appointed as private secretaries to the principal officers, with extra remuneration of from £50 to £300 a year, and more senior members are eligible for departmental secretaryships and other leading staff positions at various rates between £1,000 and £1,800 a year. As a result, advancement is so brisk that the official scales of salary already quoted are, in practice, only minimum rates, and generally prove little more than nominal.

Examples of Promotion. Such an assertion is best proved by actual illustration. The following instances will serve to establish the point. A successful competitor in 1894 went to the Inland Revenue Department, with an initial salary of £150 and a £15 increment. Within a year he received a private secretaryship at an extra £50 yearly, later another worth £100, and after less than nine years' service became a principal clerk at £600 rising to £700, when his stipend according to the official scale would have been £270. A colleague in the same office was even more successful, attaining the rank of principal clerk after only six years. In another instance known to the writer a clerk of two years' standing has already been advanced in salary from £150 to £350.

Of the posts attainable by senior officials, a few cases among many must suffice. The present Chairman of the Prison Commission entered as a Class I. clerk in 1881 ; he now receives £1,800 a year, and has had a K.C.B. conferred on him for his services. Another officer, who began his career in 1886, is Deputy-Chairman of the Board of Inland Revenue, with a salary of £1,500. Other highly-placed officials who entered by the same means include the Assistant Secretary to the Treasury (earning £1,500 a year), the Secretary to the India Office, and the Director of Admiralty Stores, each receiving a salary of £1,200, and at least three Assistant Under-Secretaries of State at the same remuneration.

The Examinations. Class I. clerkships, as well as Ceylon cadetships and appointments in the Indian Civil Service [see Imperial Service] are awarded on the results of a joint open competition held in August of each year. Candidates who are eligible, may enter simultaneously for all three classes of appointment on payment of a single fee; and if successful, are allowed, according to their position on the combined list, to select which service they will enter.

Competitors for the posts under discussion must be between 22 and 24 years of age on the 1st August of the year in which they enter, but are entitled to deduct from their actual age any time spent in the naval or military service. A further and valuable provision enables those who have been for two years or more in the national Civil Service to deduct in the same way the time so employed, up to a maximum of five years. Subordinate members of the service are thus generally entitled to compete until the age of 29 years.

The examination subjects and the maximum marks assigned to each are as follows:

Mathematics and advanced mathematics, 1,200 *each*. English, French, Italian, German, Sanscrit, Arabic, logic and psychology, moral philosophy, political economy, and the following branches of natural science—chemistry, physics, geology, botany, zoology, and animal physiology, 600 *each*.

English composition, Greek history, Roman history, general modern history, political science, Roman law, and English law, 500 *each*.

English history (i.) to 1485; (ii.) 1485 to 1848, 400 *each*. Greek: translation, composition, and literature, 300 *each*. Latin, in similar divisions, 300 *each*.

Candidates may not offer more than four natural sciences, and those who select Latin or Greek must take up translation, and at least one other division of the subject. To hinder mere "smatterers" from succeeding by sheer multiplicity of papers, a deduction may be made from the marks gained in each branch, except mathematics and English composition. There is also a new provision that in future contests a competitor's papers shall not carry a greater total maximum than 6,000 marks. Its effect will be to limit each student to some ten subjects, or twelve at most, in place of the fifteen or sixteen which many candidates have offered in the past.

Choice of Subjects. With these restrictions, any of the branches named in our list may be taken, none being obligatory. The choice thus afforded is a very wide one; and, as the examination standard in each subject is very severe, it is imperative that a careful selection should be made at the outset of the course of study. In practice, it is found that successful contestants who are not brilliant mathematicians usually take up classics or modern languages as a mainstay, with history and law or moral sciences as supplementary mark-getters, the natural sciences being seldom taken seriously. Until recently, indeed, classics were regarded as almost essential to success, but the waning importance of this branch of a liberal education is already reflected in the Class I. pass-lists. The contest of August, 1905, was marked by unprecedented features, the first three places in the combined list falling to brilliant students of Edinburgh University, not one of whom took Greek or Latin, while the foremost offered three members of the natural science groups, and scored at least 75 per cent. in each.

The number of vacancies in the home service filled by competitions during each of the past six years has been as follows: 23, 27, 21, 43, 24, and, in 1905, about a score, the exact figures not having yet been announced. At the joint examination, some 200 to 220 candidates sit each year. Of these, the great majority compete for the home as well as for the foreign service, deciding afterwards, if successful, which branch they will enter. Badly placed candidates often prefer an Eastern post to indifferent offices in the home service; but those who stand high enough to secure a good choice of departments, generally select the career afforded by a Class I. appointment. These facts are strikingly illustrated by the latest report of the Civil Service Commissioners, which shows that 181 in a total of 212 contestants entered for Class I. clerkships, and of the first 13 successful competitors on the combined list, no fewer than 11 accepted these appointments in preference to posts in the East.

University Prizes. When we consider the keen competition for these positions, the large number of subjects essential for success, and the searching character of each paper, a doubt arises as to whether Class I. clerkships are within the scope of any private student, or of a subordinate civilian who has only his evenings free for study. The doubt is more than justified, alike by personal knowledge of the many hard-working minor officials who have striven vainly for these posts, and by the published results of recent competitions. The men taking high places on the list have come from the honours schools of the sister universities, in many instances with a post-graduate course of some months in a "crammer's shop" just before the examination. Not a single post for the past three years has been won by any save college men, and among the successes, London University—that *alma mater* of the struggling student—is represented by a solitary candidate. Reluctantly one is driven to admit that, unless when some intellectual marvel is the exception that proves the rule, these valuable appointments are practically close coverts for the brilliant men of the universities, and especially of Oxford and Cambridge.

EXAMINATIONS FOR THE NATIONAL CIVIL SERVICE

Postmen, Messengers, Office Keepers and other subordinates are generally appointed after nomination by the Head of Department concerned, after passing elementary test. Junior Inspectors, Board of Education ([illegible] to [illegible]), are nominated by Secretary and appointed without examination.

Appointments.	Age Limits.	Educational standards (and special requirements, if any).	Fees.	Initial salaries, or weekly earnings, and maximum ordinarily attainable.	Average number of vacancies yearly.	Average number of candidates for each vacancy.
	APPOINTMENTS BY OPEN COMPETITION					
Posts on General Staff						
Clerk, Class I.	22 to 24	High and searching	£6	£150 or £200 to £800, £1,000	28	7
Clerk, Second Division	17 to 20	Secondary school grade	£2	£70 to £350	225	7
Assistant Clerk	19 to 21	Simple. Must have served as Boy Clerk	10s.	£55 to £150	190	3 to 4
Boy Clerk	15 to 17	Simple	5s.	15s. to 19s. weekly	800	2·5
Boy Messenger	14 to 16	Elementary	1s.	9s. to 16s. 6d. weekly	100	Qualifying exam. only
In Particular Departments						
Assistant of Excise	19 to 22	Moderate	£1	£90 to £250, etc.	103	17
Assistant of Customs	18 to 21	Moderate	£1	£70 to £250, £540	72	14
Assistant Surveyor of Taxes ..	19 to 22	Somewhat high	£6	£100 to £550, etc.	16	12
Assis. Examiner, Patent Office ..	20 to 25	Scientific subjects	£5	£150 to £450	35	4·5
Examiner, Exchequer and Audit Office	18 to 20	Somewhat high	£6	£100 to £350, £500	6	3·5
Junior Officer, Admiralty and War Office	18 to 20	Secondary school grade	£6	£100 to £500, £700	7	10
Port Service Clerk, Customs ..	17 to 20	Secondary school grade	£3	£70 to £300, £400	20	9
Clerk, Ecclesiastical Commission	18 to 22	Secondary school grade	£2	£70 to £350, £500	3	7
Estate Duty Clerk	21 to 27	Legal. Restricted to qualified solicitors	£2	£150 to £500, etc.	5	3
Clerk, Office of Woods	19 to 28	Legal. Must have been in a solicitor's office	£2	£100 to £400	Occasional	9
Sorter, Post Office	18 to 21	Elementary	4s.	18s. to £3 2s.	85	9
Learner, Post Office (London) ..	15 to 18	Elementary	4s.	8s., 16s. to £3 2s.	58	5
Learner, Post Office (Provincial)	14½ to 18	Elementary	4s.	8s., 16s. to £2 16s.	190	6 to 10
Apprentice, H.M. Dockyards ..	14 to 16	Simple	2s.	4s. to 14s. weekly while indentured	—	—
Boy Artificer, Royal Navy ..	15 to 16	Simple	2s.	3s. 6d. to 45s. 6d.	—	—
Abroad						
Student Interpreter, Turkey, Morocco, and Near East	18 to 24	Foreign languages essential	£4	£200, £500 to £1,000, etc.	4	3
Posts for Women						
Woman Clerk, G.P.O.	18 to 20	Secondary school standard	7s.6d.	£55 to £130	40	7
Girl Clerk, G.P.O.	16 to 18	Secondary school standard	7s.6d.	£35 to £37 10s.	47	9
Female Learner (London) ..	15 to 18	Elementary	3s.	7s., 14s. to £1 18s.	40	10
Female Learner (Provincial) ..	15 to 18	Elementary	3s.	5s., 12s. to £1 15s.	85	12
Female Sorter, Post Office ..	15 to 18	Elementary	2s.6d.	14s. to 30s. weekly	55	14
	APPOINTMENTS BY NOMINATION*					
Clerk and Attaché, Foreign Office	19 to 25 (after July, 1907, 22 to 25)	Languages essential. *N. Foreign Secretary*	£6	£150 to £1,000, etc.	8	4
Clerk, Royal Courts of Justice ..	20 to 30	Simple. *N. Lord Chancellor and others*	£6	£100 to £400, etc.	19	Qualifying exam. only
Assistant, British Museum ..	20 to 25	Science or Arts. *N. Principal Trustees*	£5	£100 to £500, etc.	4	3
Assistant Inspector of Mines ..	23 to 35	Mining subjects. *N. Home Secretary*	£6	£300 to £400, £800	3	1 to 4
Inspector of Factories	21 to 30 (38 for certain candidates)	Technical. *N. Home Secretary*	£3	£200 to £450, £550, etc.	4	2 to 4
Assistant to Inspector of Factories	21 to 40	Technical. *N. Home Secretary*	10s.	£100 to £150	3	1 to 3
Clerk, Prisons Service	18 to 22	Moderate. *N. Home Secretary*	£1	£70 to £300	3	—
Junior Clerk, Post Office ..	19 to 26	Secondary school subjects. *N. Postmaster General.* Restricted to postal servants	£1	£80, £100 to £200, £400	49	5
Prison Warder	24 to 42	Elementary. *N. Home Secretary*	2s.6d.	£60 to £78, etc., with allowances	80	Qualifying exam. only
Naval Appointments						
Assistant Clerk	17 to 18	Secondary school subjects. *N. First Lord of Admiralty*	£1	£45 to £400, etc.	40	3
Posts Abroad						
Student Interpreter, China, Japan, and Siam	18 to 24	Languages and law. *N. Foreign Secretary*	£4	£200 to £700, etc.	10	4
Consular Officer	22 to 30 (after Dec., 1906, 22 to 27)	Somewhat high. *N. Foreign Secretary*	£4	£200 to £700, etc.	4	5
Posts for Women						
Female Inspector of Factories ..	21 to 40	Technical. *N. Home Secretary*	£1	£200 to £300	Occasional	Qualifying exam. only
Prison Wardress	24 to 42	Elementary. *N. Home Secretary*	2s.6d.	£45 to £70, with allowances	30	Qualifying exam. only
Female Typist	18 to 30	Simple, includes Typing. *N. Heads of Departments*	1s.	18s. to 25s., 35s. weekly	43	1 to 2

*NOTE.—*N.* in column 3 signifies Nominating Authority

THE STORY OF THE ROCKS

A Chronological Survey of the Various Geological Systems.
Books for the Geological Student. Glossary of Geological Terms

Concluded from page [illegible]

By W. E. GARRETT FISHER

WE can here give only a very brief account of the chief periods which make up the geological record. We shall illustrate these as far as possible by the rocks of our own country.

Archæan Rocks. The oldest of all stratified rocks are called Archæan, or ancient. They are also known as Pre-Cambrian, because they came before the Cambrian, or oldest Primary rocks. These rocks represent the oldest stratified formations which we can study. They consist partly of igneous rocks, such as granites, which frequently have been altered into gneisses and schists; partly of sedimentary rocks, sandstones, shales and conglomerates, and partly of volcanic tuffs, conglomerates, and sheets of lava. These oldest sedimentary rocks very seldom contain any remains of organic life, though here and there some relic of the first beginning of life on the earth is found even in these most ancient formations. The chief mountains of the Scotch Highlands are formed of the Archæan igneous rocks, whilst the sandstone hills of Loch Torridon may represent the Archæan sedimentary rocks.

Primary Rocks. Cambrian System. The next great division of rocks is known as Primary; it is also called Palæozoic, because it contains the most ancient relics of life in the shape of numerous fossils [81]. The oldest members of this division form the Cambrian System of rocks, so called because they were first studied in Wales, where they form the great series of slaty rocks which provide so many quarries, whilst Snowdon and its neighbouring peaks, like Scaw Fell, in Cumberland, are formed from volcanic rocks which were produced about the same time that these slates were deposited in the shallow seas of the Cambrian age.

81. CAMBRIAN FOSSIL

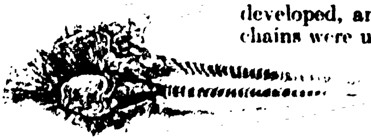
82. SILURIAN FOSSIL

Silurian System. The next system of Primary rocks is the Silurian, so called because it was first examined in the Shropshire district once occupied by an ancient British tribe called the Silures. This system consists chiefly of a series of sandstones, gritstones, shales and slates, with occasional strata of limestone. The hills of the Lake District are largely composed of Silurian rocks, which also form the greater part of the southern uplands of Scotland. The Silurian system is of special interest to the geologist, because it is in these rocks that we find the earliest traces of vertebrate life [82]—the first recognisable ancestors of man.

83. COPROLITE, OR FOSSIL EXCREMENT

Devonian System. The next system consists of the marine sediments, or limestones, which are called Devonian because they are commonly found in Devonshire. They consist mostly of sandstones, limestones, and shales, which are rich in the fossil remains of marine organisms [84], and also contain frequent veins of metallic ores. They may be well studied in the slates of Ilfracombe and in the limestones of Torquay. Closely allied with the Devonian system is the Old Red Sandstone, or the series of red sandstones, shales, and conglomerates which interpose in many districts between Silurian and Carboniferous rocks. The Old Red Sandstone was also laid down under water, since it contains the fossil remains of fishes, which Hugh Miller described so delightfully. This Old Red Sandstone, which has been moulded by denuding agencies into so many hilly districts, forms a great part of characteristic Scotch scenery; the volcanic rocks which have been freely intruded into these masses, being harder than sandstone, have been left standing up in ranges of hills like the Pentlands and Cheviots.

Carboniferous System. The next system of Primary rocks happens to be by far the most important of all rocks to mankind. This is the Carboniferous System, which includes the coal measures, to the energy stored in which we owe practically the whole of the industrial achievements of the last century. The carboniferous rocks consist of the coal measures, or layers of coal mingled with shale and sandstone, of the millstone grits, and carboniferous limestones. The coal seams consist of the decayed vegetable matter of ancient forests, laid down in beds in the manner described in an earlier section, resting on layers of clay, and divided by strata of shale and sandstone, which were laid down during the periodical submergence of the bed of each forest. The carboniferous rocks cover a large area of the surface of these islands, such as the great central coal field of Scotland and the important coal fields which lie on either side of the Pennine range and in South Wales. The total thickness of the coal measures amounts in places to more than two miles, though the actual seams of coal occupy only a few score feet in thickness. These coal seams are entirely made up of fossil vegetation, but contain few animal remains. The carboniferous or mountain limestone which is frequently found associated with the coal measures, and forms the great Pennine range or backbone of England, is almost entirely composed of the remains of minute organisms, such as corals and foraminifera, which lived in the seas of the Carboniferous Age.



84. FOSSIL FROM OLD RED SANDSTONE

Permian System. The last or youngest system of the Primary rocks is known as the Permian. It includes the lower strata of what is known as the New Red Sandstone. The distinction between the upper and lower strata of these sandstones is chiefly due to the difference in the fossils included in them, which shows that a considerable period must have elapsed between their formation. The Permian rocks are very barren in fossils. They are seen to best advantage in the valleys of the Nith and Annan in South-west Scotland. To the same period belongs the great mass of magnesian limestone which runs down the East of England.

Secondary Rocks. We now come to the third of these great divisions, that of the Secondary, or Mesozoic rocks, so called because they are thought to represent what may be called the middle period in the development of life.

Triassic System. The oldest system of the Secondary rocks is known as Triassic, and includes the upper layers of the New Red Sandstone, formed also in the beds of ancient seas. The low-lying plains in the centre of England are largely formed of Triassic rocks, which may be studied where they reach the seashore at Lyme Regis or Budleigh Salterton.

Jurassic System. The next great system is that of the Jurassic rocks, so called because they compose the great mass of the Jura Mountains. They are very rich in fossils, especially in reptilian forms, such as the ichthyosaurus and the turtle-snake plesiosaurus. They largely consist of *oolitic* limestones, so called because of their egg-like structure. The well-known Oxford clay and Portland stones are familiar examples of Jurassic rocks.

Cretaceous System. The last of the three great Secondary systems is that of the Cretaceous, or chalky rocks. These vast deposits of chalk and allied rocks mainly consist of the shells and skeletons of tiny marine organisms which lived in the Cretaceous seas and deposited their hard portions upon their beds in vast masses. They are best illustrated, of course, by the imposing chalk cliffs which fringe a great part of our Channel coast, and which can be traced from Flamborough Head in Yorkshire to the coast of Dorset. These deposits are very rich in fossils, in which we notably see the Jurassic reptiles passing into the earliest bird forms.

Tertiary Rocks. The fourth of the main divisions into which the rocks of the earth's crust are classified in the geological record is called the Tertiary, or Cainozoic, because it contains the traces of recent life. It is usually divided into four systems. It was during this Tertiary period that the present distribution of land and sea into the continents and oceans which now appear in our maps was finally developed, and that most of our mountain chains were upheaved. Volcanic activity was very marked in all parts of the world, and there were great variations in climate from those of the present time, tropical conditions appearing in great part of what we now call the temperate zone.

Eocene System. The oldest of the Tertiary systems contains the Eocene rocks, on which London stands. The Eocene rocks consist almost entirely of sand and clay, more or less hardened. They appear to have been laid down either in fresh water or near a coast line, as we infer from the nature of the fossils which they contain. One of the oldest and most notable of Eocene rocks is the London clay, so called because of its general distribution throughout the basin [85] in which the metropolis is situated. It is a stiff brown or bluish clay, which contains numerous fossils and nodules of clayey limestone. A more recent Eocene rock may be seen in the Bagshot sands, consisting of yellow siliceous sand, with few fossils, but containing the large sandstone blocks known as Grey Wethers or Druid Stones.

Oligocene System. The next series of Tertiary rocks is known as the Oligocene rocks. This includes the thinly-bedded deposits of sand, clay, and limestone which are found in the Isle of Wight. They were apparently laid down in shallow brackish water, and contain numerous fossils, among which we may specially note the abundant variety of insect life which appears to have existed in Oligocene times.

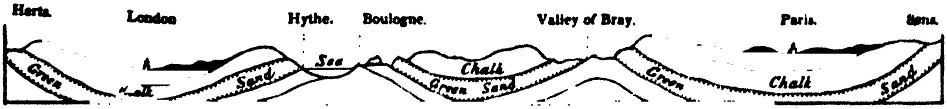
Miocene System. The Miocene system, which comes next, coincides with a chronological period in which our islands and the greater part of Northern Europe had been gradually elevated above the sea. Consequently no Miocene deposits are known to occur in our islands, since they were only laid down under water, and this part of the world then consisted of dry land. As far as we are concerned, the Miocene age was an age of denudation and land-moulding rather than of construction. Where they exist, as in France, the Miocene beds chiefly consist of sand and gravel rocks. They are rich in fossils, in which we see a gradual approach to the fauna of the present day.

Pliocene System. The last of the four great Tertiary systems is known as the Pliocene.

During this period there seems to have been local subsidences in the British Islands, and consequently Pliocene deposits appear in some parts of the country, chiefly in the counties of Norfolk and Suffolk, where they constitute the accumulations of sandy rocks known as Crag.

Quaternary Rocks. The last of the great divisions of the geological record is known as the Quaternary or Post-tertiary. This division reaches down to our time; we are living, in fact, in the Quaternary Age. It is usually divided into two systems—the Glacial, or Pleistocene; and the Post-glacial, or Human Period, during which man is known with certainty to have been in course of development.

Pleistocene System. The Glacial Period. The Pleistocene system of rocks received its mould during what is known as the Glacial Period, or Ice Age, which divides the modern geological history of the Northern Hemisphere from all that has gone before. During the greater part of this period, which is but of yesterday in comparison with the vast age of the systems which we have hitherto been considering, the whole of our islands and of Northern Europe was buried under a vast sheet of ice, which may have been as much as a mile in thickness in parts of Britain. The whole of our country is full of evidence of the former existence of these gigantic glaciers. Everywhere the land contours have been rounded and smoothed by glacial motion, whilst the various signs of glacial action which we described in an earlier chapter are abundant; polished and striated stones, erratic blocks, moraines, and the other symptoms associated with the presence of glaciers are to be found in all parts of our country. A great deal of the surface of our islands is covered with *boulder-clay*, or *till*, a mass of earthy, stony, and sandy material which is an unmistakable product of glacial action. During the Glacial Period there is little doubt that the land of the Northern Hemisphere underwent various elevations and subsidences, the traces of which are preserved in the form of submarine deposits and aerial denudations. It is probable that, although throughout the Pleistocene period our islands were more or less glaciated, there were temporary alleviations in the climate. Some have professed to have traced as many as five distinct periods during which ice covered the land, with intervals of a mild and open climate. However that may be, there is no doubt whatever that the Glacial Period stamped its mark upon our landscape shortly before man came into existence, or at least began to inhabit this part of the world. These Pleistocene deposits are almost entirely made up of boulder-clay and similar glacial beds, which, as we might expect, are somewhat poor in fossils, those which exist being chiefly the remains of Arctic land animals and of marine organisms.



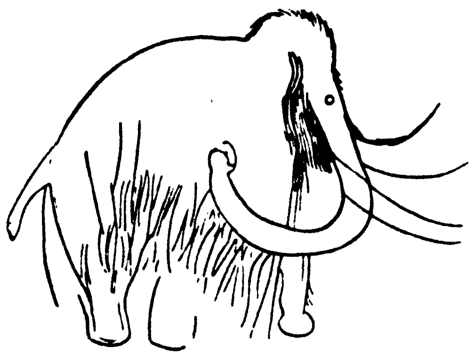
85. LONDON AND PARIS BASINS (Lyell)

Post-Glacial Period. The last period in the geological record, in which we are still living, is known as the Recent, Post-glacial, or Human Period. No rocks of any great importance have been formed during this period, although, of course, the general agencies of denudation and reconstruction have been at work to modify the face of the land. But even the hundreds of thousands of years which are believed to have elapsed since the ice disappeared from our islands are but a day in the sight of the geologist, and they have not sufficed to destroy the general outlines and nature of the land as these were left at the close of the Glacial period. The most interesting fact connected with these recent deposits is that they contain proofs of the early existence of man. His primitive instruments, first of rudely-chipped flint, then of smooth and beautifully-worked flint, then of bronze and afterwards of iron, are found buried in the deposits brought down by rivers, strewing the floor of the ancient caverns which he shared with the cave bear and the sabre-toothed tiger, and buried deep beneath the soil of the earth by the action of the various denuding and constructive agencies. Along with these tools have been found some very interesting drawings, scratchings on bone or ivory, which have thrown great light upon the habits of prehistoric man [85]. The history of our species, before history properly so called began, is divided by geologists into Palæolithic and Neolithic times, during which man made his implements solely of flint and bone. The alluvial deposits, or river drifts, have given up much evidence bearing upon the nature and habits of man when he first emerged upon the stage of the world, as may have happened in our hemisphere shortly after the close of the glacial period, probably from one to two hundred thousand years ago, but the study of these comparatively recent times is outside the sphere of geology proper, and belongs rather to the anthropologist and archæologist.

Bibliography. The student who has mastered the outline of geology given in this course will now desire to know what books he should read in order to enlarge his knowledge. There is a large supply of such works in our language, without mentioning the admirable treatises which are only available to those who can read French and German. Amongst these the following works are deserving of special recommendation.

General Treatises. The best work in our language is, without doubt, Sir Archibald Geikie's large "Textbook of Geology" (Macmillan. 2 vols. 30s. net), of which the fourth edition was published in 1903. This admirable and lucid exposition of the science of the earth holds the place which was occupied for many years by Sir Charles Lyell's "Principles of Geology." The student who has gone through it with the assistance of practical work in the field and the laboratory will have little left to learn. The same author has published two works on a smaller scale—"Primer of Geology" and "Classbook of Geology" (Macmillan. 1s. and 5s.)—which may equally be recommended to those who have less time available. Dr. J. E. Marr's "Introduction to Geology" (Cambridge University Press. 3s. net) is perhaps the best of recent attempts to explain the scope and methods of geology, without an excess of detail. Professor A. H. Green's "Physical Geology" is a valuable supplement to Geikie, and the latest American work, Messrs. Chamberlin and Salisbury's "Geology" (Murray. Vol. 1. 21s.) handles the process of physical change in a new and illuminative fashion.

Practical Treatises. The best account of methods of geological investigation on a small scale is to be found in Sir Archibald Geikie's "Outlines of Field Geology," fifth edition (Macmillan. 3s. 6d.), which may be supplemented by W. H. Penning's larger "Textbook of Field Geology" (Baillière, Tindal, & Cox).



86. MAMMOTH ENGRAVED ON WALL, CAVE OF COMBARELLES, DORDOGNE

Special Surveys. The geology of a particular country affords a very interesting and instructive field of study. Three books on this subject deserve special mention: Sir Archibald Geikie's admirable "Scenery of Scotland" (Macmillan. 10s. net), Mr. A. J. Jukes-Browne's "Building of the British Isles" (Bell. 7s. 6d.), and Lord Avebury's "Scenery of Switzerland" (Macmillan. 6s.). There are similar treatises, in various languages, for nearly every country in the world, but these three will afford the English student plenty of occupation to begin with.

History of Geology. The first four chapters of Lyell's "Principles of Geology" contain an outline of the history of geology. Sir Archibald Geikie's "Founders of Geology," second edition (Macmillan. 10s. net), gives a fuller account of the growth of this science from the earliest times, treated in a biographical fashion. Mrs. Ogilvie Gordon's abridged translation of the German Professor Zittel's "History of Geology and Palæontology" (Scott. 6s.) is also a valuable book of reference.

Mineralogy. The leading English textbook of mineralogy, which describes the nature and explains the identification of the various minerals which go to the building up of rocks, is Professor Henry A. Miers's "Mineralogy" (Macmillan. 25s. net). The American Dana's "System of Mineralogy" is still the standard work of reference. Among the numerous smaller handbooks, F. Rutley's "Mineralogy" (Murby. 2s.) is still as good as any.

Palæontology. The chief work on palæontology, or the geological record of ancient life, is the English translation of Professor Zittel's "Textbook of Palæontology" by C. R. Eastman. Dr. A. Smith Woodward's "Outlines of Vertebrate Palæontology for Students of Zoology" is a valuable help.

Departments of Geology. The works dealing with special departments of geology are very numerous. We may mention Professor Milne's "Earthquakes" and Professor Judd's "Volcanoes," both in the International Science Series (Kegan Paul); Mr. Davison's "Study of Recent Earthquakes" and Professor Hull's "Volcanoes, Past and Present," in the Contemporary Science Series (Scott); Sir A. Geikie's "Ancient Volcanoes of Great Britain" (Macmillan. 36s. net); Tyndall's "Glaciers of the Alps" and Sir R. Ball's "Cause of an Ice Age." Professor James Geikie's works on "The Great Ice Age" and "Prehistoric Europe" give the best account of geologically recent times. Hugh Miller's "Old Red Sandstone" may still be read with pleasure for its fascinating pictures of a vanished era, though it is somewhat out of date. Professor Hull's books on "The Coal Fields of Great Britain" and "Our Coal Resources" are important contributions to a special field of geological work. By the time he has read all these books, the student should require no further advice as to his work.

Geological Maps. It is impossible to study the geology of a district without a good map. The best maps are those published by the Geological Survey of Great Britain, and by similar organisations in most civilised countries. These are on scales ranging from 6 in. to the mile to 4 miles to the inch; the latter scale is large enough for most purposes of the student, who will do well to obtain the sheets for the districts with which he is most familiar, and study them carefully on the ground. Small-scale geological maps of a whole country, such as are published by Messrs. Bartholomew, Stanford, and Philip, will also be found indispensable.

Geology concluded

A SHORT DICTIONARY OF TERMS USED IN GEOLOGY

It is impossible to include the names of rocks and minerals in the space that can be devoted to this glossary. Most of them are explained in the course

ÆOLIAN, or AERIAL DEPOSITS—Those produced by the action of atmospheric agencies.
Amorphous—Without definite structure.
Anticline—A tilting of strata into an arch.
Aqueous Deposits—Deposits due to the action of water.
Archæan—The most ancient rocks.
Arenaceous Rocks—Sandy rocks.
Argillaceous Rocks—Clayey rocks.
Atmosphere—The gaseous envelope surrounding a planet.
Axis—The line about which a crystal or other structure displays symmetry.

BEDDING—The arrangement of rocks in layers or bedding planes.
Boss—A mass of volcanic rock pushed up to the surface.
Boulder Clay—A stiff clay full of stones and boulders, left by glacial action.

CAINOZOIC—The period of recent life.
Cambrian — The oldest Primary system.
Calcareous—Limy rocks.
Carbonaceous—Coal-bearing rocks, or those containing carbon.
Carboniferous—The fourth Primary system, including the coal measures.
Catastrophe, or Cataclysm—A convulsion of Nature which causes great and sudden geological changes.
Cleavage—The division of a rock into layers, due to pressure.
Clinometer—An instrument for measuring the slope of strata.
Colloid—A jelly-like, non-crystalline mineral structure.
Conformable—Strata laid down regularly on one another.
Contour Line—A line drawn through a series of points at the same height on a map.
Crater—The basin into which a volcanic vent opens.
Cretaceous—The latest Secondary system.
Crystalline Minerals or Rocks—Those consisting of crystals, or symmetrical structures produced by cooling or precipitation.
Crust—The upper solid portion of the earth.

DÉBRIS, or DETRITUS—The remains of rocks broken down by erosion or denudation.
Denudation—The wearing away of rock by natural agencies.
Derivative Rocks—Rocks produced by some modification of an older rock.
Devitrification—The loss of glassy characteristics, due to weathering.
Devonian, or Old Red Sandstone—The third Primary system.
Dip—The slope of strata from the horizontal.
Dislocation—A fracture in rocks accompanied by disunion of the strata.
Dyke—A vertical seam of volcanic rock, usually found standing up like a wall.

EARTHQUAKE—A rapid movement of the earth's surface.
Eocene—The oldest Tertiary system.
Epigene—Above the surface of the earth.
Erratic Blocks—Boulders transported by glaciers.
Erosion—Wearing away of rocks by natural agencies.

FAULT—A dislocation.
Fissure—A crack in rock formations.
Fluviatile—Pertaining to rivers.
Foliation—A leaf-like structure in certain minerals.
Fossil—The remains of a plant or animal preserved in stratified rocks.
Fossiliferous Rocks—Rocks which contain fossils.

GEOLOGY—The science of the earth.
Geyser—An intermittent fountain of heated water.
Glaciation—The action of glaciers on rocks.
Glacier—A river of ice.
Grey Wethers—Blocks of Eocene sandstone, known in Wiltshire as Druid stones.

HADE—The angle of a dislocation to the vertical.
Hydrosphere—The watery envelope partly surrounding the earth.
Hypogene—Subterranean.

IGNEOUS ROCKS—Those formed by the action of heat.
Impermeable—Through which water cannot penetrate.
Intrusive Rock — A rock forced through an older formation.

JOINTS—Natural divisions in rocks, usually more or less vertical.
Jurassic — The middle Secondary system.

LACUSTRINE—Pertaining to a lake.
Lagoon—A salt water lake connected with the sea.
Lake—A body of fresh or salt water entirely surrounded by land.
Lamina—A thin plate.
Lithosphere—The solid globe of the earth.
Loam—A fertile soil, consisting of clay and sand with a mixture of organic matter.

MAGMA—The viscous liquid from which the igneous rocks solidified.
Marine—Pertaining to the sea.
Marl—A calcareous clay.
Matrix—The general body of a rock in which other substances are embedded.
Mesozoic—The middle period of life on the earth.
Metamorphic Rocks—Those which have been modified by heat, pressure, or chemical action.
Mineral—A chemical element or inorganic compound of which rocks are formed.
Mineralogy—The science of minerals.
Miocene—The third Tertiary system.
Moraine—The accumulation of earthy and stony matter left by a glacier.

NEBULA—A celestial body composed of gas or of a cloud of meteorites—the raw material of stars and planets.
Neck—The solidified pipe of lava of an extinct volcano.
Neozoic—The period of recent life.

OLIGOCENE—The second Tertiary system.
Outcrop—The part of a rock stratum which emerges on the earth's surface.

PALÆOZOIC—The period of most ancient life.
Permeable—Through which water can pass.
Permian — The youngest Primary system.
Petrography—The science of rocks.
Planes—The roughly parallel divisions of rocks caused by cleavage, stratification, etc.
Pleistocene—The glacial or older Quaternary system.
Pliocene — The youngest Tertiary system.
Post-Glacial—The Human Period.
Plutonic Rocks—Those igneous rocks which have taken shape below the earth's surface.
Pre-Cambrian—The oldest system of stratified rocks.
Primary Rocks—The second oldest of the five main divisions of stratified rocks.

QUATERNARY—The most recent stratified rocks.

RIB—A kind of wall of stone.
Roches Moutonnées—Rocks rounded by glacial action so that at a distance they look like sheep.
Rock—A mass of earthy or stony matter composed of one or more simple minerals.

SEAM—A layer of mineral, usually applied to coal.
Secondary—The third of the five periods of stratified rocks.
Secular Movements — Those prolonged through many centuries or ages.
Sedimentary Rocks—Those produced by the solidification of sediments left by water.
Seismic—Relating to earthquakes.
Siliceous Rocks—Flinty rocks.
Sill—A layer of volcanic rock.
Silurian—The second Primary system.
Soil—The detritus covering the earth's surface and capable of supporting vegetable life.
Spicule—A needle-shaped body.
Strata—Layers of rock, usually more or less horizontal.
Stratified Rock—Rock arranged in definite layers.
Striation—Scratching of stones due to glacial action.
Strike—The direction of the outcrop of strata.
Subsidence—The gradual sinking of the land.
Subsoil—Consisting generally of earth and stones, intermediate between the soil and the solid rock.
Syncline—An arrangement of tilted strata in troughs.

TERTIARY — The fourth period of stratified rocks.
Throw—The vertical displacement of strata by a dislocation or fault.
Till—Boulder clay.
Triassic — The oldest Secondary system.
Tuff—Volcanic débris, often hardened into rock.

UNCONFORMITY—The disposition of a set of strata upon older ones which lie at a different angle.
Uniformitarianism — The doctrine that similar causes have been at work throughout geological history to produce the same results.
Upheaval—The slow rising of the land.

VENT—The communication between a crater and the subterranean reservoir of molten lava.
Vitreous—Glassy rocks or minerals.
Volcano—A mountain produced by the ejection of lava from the interior of the earth.
Volcanic Rocks—Igneous rocks which have solidified on the earth's surface.

WEATHERING—The modification of rocks by atmospheric or meteorological agencies.

THOUGHT AND MEMORY

The Function of Attention, and its Relation to Thinking Power. Memory and Efforts of Memory. Association of Ideas. How to Gain Knowledge

By Dr. C. W. SALEEBY

DIRECTLY we think of it, we recognise the remarkable fact which the Germans call the *narrowness of consciousness*. A thousand impressions are affecting our sense organs, but we tend, when fully awake, to ignore nearly all and to attend to one or to one group of them. A distinguished psychologist, in a quite recent book, calls this a mystery, but the remarkable work of a physiologist, Professor Sherrington, of Manchester, has gone very far to explain the mystery. He is the greatest living student of reflex action, and he has shown that it is a characteristic of one or another of many stimuli that may be simultaneously striving to gain our attention, to arouse a series of reflex actions, and, at the same time, to inhibit all other competing stimuli from affecting us.

One Thing at a Time. Hence it is that we are able to give our undivided attention to one thing at a time, and hence also, ultimately, is the reason why the will is not divided and why we do not simultaneously attempt to perform half a dozen actions that are mutually incompatible. Professor Sherrington has shown, for instance—and the discovery is typical of all action—that when two objects are simultaneously presented to the eye the rays of light from each of them strike the retina at a particular point. The natural reflex in each case causes such a movement of the eyeball that the most sensitive part of the retina is swung round so as to coincide with that point, and so as to make vision most accurate. Now, supposing both of these objects are to the left, the rays of light from each of them tend simultaneously to arouse movements in the muscles which swing the eyeballs to the left. If, as might be expected, the two stimuli were added together, the eyeball would be swung too far round, and neither object would be clearly seen. On the other hand, if a compromise were struck between the two stimuli, the eyeball would swing round too far for clear vision of the one object, yet not far enough for clear vision of the other.

But what actually happens is neither of these things. One stimulus or the other captures the whole machine, so to speak, so that the image of the corresponding object is clearly thrown upon the most sensitive part of the retina. The reflex thus initiated is able completely to inhibit the action of the other reflex.

The Sense Telephone. This great discovery by Professor Sherrington that reflexes inhibit one another, has explained how it is that our complex nervous system, with its millions of reflex arcs, acts as a unit, and has also provided us with the key to the extraordinary phenomenon of attention. The professor has shown that there is a *common path* which corresponds to the trunk line of the telephone. When one subscriber gains possession of this, the others must wait. Similarly, one series of sensory fibres, as, for instance, the auditory nerve when we listen to something that deeply interests us, has captured the common path and inhibits the action of all other sensory impulses, so that we do not withdraw our hand even when someone pinches it very firmly. We desire to emphasise the assertion that this discovery constitutes the most important substantial advance in our knowledge of attention, and in our knowledge of voluntary action, since Herbert's Spencer's great discovery of the evolution of will from reflex action.

It is a noteworthy and important fact that, though children readily respond to exciting stimuli from without, "they have very few organised interests," as Professor James says, "which enable them to sustain their interest." Hence that extreme mobility of the attention with which we are all familiar in children. Here we see how simple is the determination of the attention by any new stimulus, where the mind is not sufficiently developed to enable it to retain its interest in the matter in hand. The first importance of these facts is this: that the child's incapacity for sustaining its attention has to be recognised in education. In the case of a young child, it does extremely well to attend for a quarter of an hour to any one subject that entails difficulty. It is an almost invariable fact that the lessons given to our school children are individually too long.

Thinking Power. On the other hand, it is the duty of the teacher to train the attention—to train it, but not to strain it. The importance of training it is overwhelming, though people vary very much in this respect, some requiring to undergo severe conscious discipline, which is superfluous for others. But the faculty of keeping to the point, the faculty of sustaining the attention, notwithstanding difficulty, notwithstanding the temptations of all sorts of by-paths, is one of the highest, rarest, and most valuable characters of the human mind. The present writer is very far, indeed, from accepting the view of Carlyle, "that genius is an infinite capacity for taking trouble." He infinitely prefers Carlyle's much truer dictum that "genius is the clearer presence of God Most High in a man." But the familiar quotation expresses a very important fact. No matter what the native genius may be, it cannot yield its due fruit unless there be a great power of attention. At any debate one can recognise in a moment the difference between those who are able to attend and those who are diverted by chance associations—in short, those who have thinking power and those who have not. The power of public speaking, or of writing coherently and consecutively on any subject, entirely depends upon the faculty of sustaining the attention, notwithstanding a thousand temptations to wander, temptations induced by sensations from without or by random ideas from within.

Attention Essential in all Things. Two great practical points emerge from the very brief study of this subject which we have been able to afford. First, that the due understanding of the evolution of attention in the individual would so modify our educational practice as to make lessons far more attractive to children, far more useful, and truly *educative*—that is to say, a "drawing out" of the mind—rather than, as often happens when attention is demanded for excessive periods, blunting interest and repressing the mental faculties. Secondly, the power of attention is an essential for every kind of successful mental work; it applies alike to the solution of a geometrical problem, writing an essay, making a speech, or playing a sonata. He who desires to make the most of his inherent mental powers must consciously develop the power of attention. If these pages lead him to follow our advice, the SELF-EDUCATOR will be worth many times its weight in radium.

Memory. Now, if the faculty of attention be important, what are we to say of the faculty of retention—the faculty of memory? If we could not remember we could not learn, and this is true alike of learning to write or learning to walk. Now, memory unquestionably has a physical basis, and this basis is fundamental to all those actions of the mind in which memory is involved. Habit, for instance, may very well be defined as organic memory. Professor James says: "An acquired habit, from the physiological point of view, is nothing but a new pathway of discharge formed in the brain by which certain incoming currents ever after tend to escape." That definition will be perfectly intelligible to the reader of what we have already said regarding reflex action. As Professor James points out, this definition of habit—the formation of pathways of discharge—helps us to understand not only habit itself, but also what we commonly understand by memory, the association of ideas, perception, and reasoning. When we acquire a habit, or when we remember, it means that some change of greater or less permanence has been produced in our nervous tissues; and this, indeed, is the supreme feature of nervous tissue—its plasticity, its modifiability, its power of learning and remembering.

Now, there are certain facts which go some little way, at any rate, towards illustrating the very simplest aspects of memory. There are many toys, such as the kaleidoscope and the now familiar cinematograph, which depend for their success upon what are called after-sensations or after-images. In the case of the eye, to take an instance, the sensation aroused by the light from an object momentarily thrown upon it lasts for about one-fortieth of a second after the light is withdrawn. Plainly, then, there is the persistence of something in the retina, and that something, of course, is the change which the light induced. There are many popular experiments, sometimes used in advertisements, which employ this principle.

Memory Images. But from these we may turn to what are called *memory images*, the sense of sight again serving us conveniently for illustration. After we have looked carefully at any object that is not too complex, we can shut our eyes, and for a short time afterwards we can recall the image of that object. It would be idle to attempt any assertion as to what actually happens in such a case. But, at any rate, it is evident that there must be some physical basis, whether in the retina or in the brain—some physical change which enables us to remember. Furthermore, the experiment illustrates two facts of memory which should never be confused—the power to retain and the power to recall. In this case it is plain that something has been retained, and it is also plain that somehow, when we try, we can actually recall. Speaking generally of the whole aspect of memory, different persons vary widely in these two aspects of the faculty and also in the proportion between them. It is perfectly familiar to all that one may have a name in one's head but may not be able to recall it. This we indicate by saying "I have forgotten the name for the moment." The retentive aspect of memory is not defective, but the power of recalling what is retained is slightly imperfect. We may add also that in complete memory one knows that one is remembering. Thus Professor James says: "Memory is the knowledge of an event or fact, or perhaps of a former state of mind, with the additional consciousness that we have thought or experienced it before." Now, in so far as retention is concerned, there is no more that is essential to be said.

"Trying to Remember." In order to understand the power of recalling or recollecting or reproducing any past mental state, we must plunge into a great subject which is called the *association of ideas*. This is one of the most important principles in psychology, and has been especially studied by the Anglo-Saxon school of psychologists. It was first definitely formulated by Hobbes, and has been greatly contributed to by Lok, James Mill and his son (John Stuart Mill), Alexander Bain, and Herbert Spencer. We may follow Professor James in quoting the admirable description given by the elder Mill of the manner in which recollection is achieved by the association of ideas. "There is a state of mind, familiar to all men, in which we are said to remember. In this state it is certain we have not in the mind the idea which we are trying to have in it. How is it, then, that we proceed, in the course of our endeavour, to procure its introduction into the mind. If we have not the idea itself, we have certain ideas connected with it. We run over these ideas, one after another, in hopes that some one of them will suggest the idea of which we are in quest, and if any one of them does, it is always one so connected with it as to call it up in the way of association. I meet an old acquaintance whose name I do not remember, and wish to recollect. I run over a number of names, in hopes that some of them may be associated with the idea of the individual. I think of all the circumstances in which I have seen him engaged, the time when I knew him, the persons along with whom I knew him, the things he did, or the things he suffered, and if I chance upon any idea with which the name is associated, then immediately I have the recollection ; if not, my pursuit of it is in vain."

Association of Ideas. There is another set of cases, very familiar, but affording very important evidence on the subject. The elder Mill goes on : "It frequently happens that there are matters which we desire not to forget. What is the contrivance to which we have recourse for preserving the memory—that is, for making sure that it will be called into existence when it is our wish that it should ? All men invariably employ the same expedient. They endeavour to form an association between the idea of the thing to be remembered and some sensation, or some idea which they know beforehand will occur at or near the time when they wish the remembrance to be in their minds. If this association is formed and the association of idea with which it has been formed occurs, the sensation, or idea, calls up the remembrance, and the object of him who formed the association is attained. To use a vulgar instance, a man receives a commission from his friend, and, that he may not forget it, ties a knot in his handkerchief. How is this fact to be explained ? First of all, the idea of the commission is associated with the making of the knot. Next, the handkerchief is a thing which it is known beforehand will be frequently seen, and of course at no great distance of time from the occasion on which the memory is desired. The handkerchief being seen, the knot is seen, and this sensation recalls the idea of the commission, between which and itself the association had been purposely formed."

Thus we *recall* by the machinery of *association*, which we shall discuss later. Meanwhile we must refer to certain practical points of great interest in relation to memory.

The Two Kinds of Memory. There are quite definitely two distinct kinds of good memory, one of which, for convenience, we may call inborn and the other acquired. Fortunate is he who can combine both. The good memory, which is a piece of native good fortune, depends upon direct retentiveness of the nervous tissue of the individual. People so blest hear a name, or a date, or a quotation, and, when occasion arises, it is found that these things are remembered. Such people have an enormous advantage over their neighbours who, having reached adult life, can do very little more than relearn that which they have already known but are constantly forgetting. These latter people cannot go on ; whereas those who have a really fine native memory are able to advance until old age creeps upon them. But as we grow old our nervous tissue loses whatever retentiveness it had—that is to say, it loses any power of making any fresh retentions, whereas memories of childhood may remain. There is no evidence whatever that this inborn peculiarity of nervous tissue can be modified by any device.

How to Make our Knowledge ours. But, on the other hand, a good memory may mean not any special power of retentiveness but the possession of good and numerous associations in the mind. The greater the number of associations of any given fact, the more surely shall we retain our memory of it. Now, in the case of intellectual knowledge, the number of associations depends entirely upon the extent and value of the reflection to which the matter in question has been subjected. The more we co-ordinate, or colligate, or associate, our knowledge or experiences, the more surely are they ours. Now, of course, we think most about what most interests us, and so our memory will be good accordingly. The present writer is absolutely incapable of remembering stories; he does not remember the plot of any of the novels which he used to read, and can scarcely ever recall even a good joke. Other people who have a natural interest in them, will retain the plots of novels in the most remarkable fashion. We often exclaim in wonder at the amazing extent of knowledge which a specialist of any order no matter whether a chauffeur or a cardinal, possesses of the particular subject which concerns him. The reason is, in the first place, that the facts of this subject have been fully perceived in the first instance, but more especially that they have been interwoven with one another so that they all hang together. They have been interwoven because they have been thought about, utilised, and correlated, and it is the law of the association of ideas that fully explains the possession of good memories of this type.

CONSTRUCTING BRICK WALLS

Setting and Laying Footings. Plumbing the Angles. A Fair Face. Damp Courses. Hollow Walls and Air Bricks. Corbelling and Cornices. Mortar Joints

Continued from page 2178

By Professor R. ELSEY SMITH

WE are now in a position to consider the actual method of carrying out brickwork. The necessary excavation will have been made by the excavator and the trenches filled in to the required depth with a layer of concrete, the top of which is left level and true. The standards for the scaffold and at least one or two ledgers will have been got into position, so that the bricklayers' work, when it commences, may proceed without interruption.

Setting out the Walls. The position of the walls and their footings will have been previously marked, and the first operation will be to test the accuracy of the concrete in relation to the position of the walls, and to mark on the concrete foundations the position of the angle bricks of the footings by straining lines between the setting-out boards [see page 309]; a plummet should be dropped from their intersection and a brick accurately set on a small mortar bed to mark each angle; the dimensions should be carefully checked over again after the bricks are actually set out so that any slight inaccuracy may be corrected while this is still an easy matter.

Laying the Footings. When the setting out is verified the actual laying of bricks begins with the bottom course of footings. *Footings* consist of a base wider than the wall itself, and serve to increase its stability and to distribute its weight over the wider area of the concrete. In London, footings are required by the London Building Act, 1894, to all walls except those which rest upon girders; the minimum width of the bottom course of footings is required to be twice the width of the wall under which it occurs, and the total height of the footings is required to be, as a minimum, two-thirds of the width of the wall at its *base*—that is, at the course next above the footings. These rules are very generally accepted as the reasonable minimum requirements beyond the jurisdiction of the London Building Act. The footings of brick walls are formed of successive courses of bricks; the minimum size of each course is made one half-brick wider than the course above it, and projects beyond it 2¼ in. both in front and at the back. It will be seen, therefore, that to provide the requisite width of footings one course will be required for every half-brick in the thickness of the wall, and as the height of a brick (3 in.) is two-thirds of the width (4½ in.), this number of courses will also give the requisite height for the footings.

Bond of Footings. Footings are, with very rare exceptions, buried below the ground level, and we need not, therefore, consider the appearance of them as of such importance as to make us abandon the most suitable method of construction; whether the wall above is English or Flemish bond, the footings in all cases are laid in header bond. If the footings to a wall having a stopped end be examined [72], it will be observed that this secures a perfect system of bonding without the use of closers; for each course projects at the end of the wall 2¼ in., or the width of a closer, and also, as already pointed out, to the same extent both in front and rear, and a very thorough and complete bond results. The great advantage of using nothing but headers will be observed in looking at a cross section [73], for in each course the headers that form the front row cover the bricks below, which are also headers, to the extent of 6¾ in. by 4½ in., or three-fourths of the entire area; whereas, if the brick below were a stretcher it would be covered only to the extent of 2¼ in. by 9 in., or one half its area. And as one of the important functions of these footings is to distribute the pressure from the wall outwards, this arrangement is clearly one that will perform this duty with the least likelihood of producing a fracture. It is, however, obvious that, as the width of the footings increases by only a half-brick in each course, a single course of stretchers must be used in every alternate course; but, excepting in the case of the first course of footings to a one-brick wall, this never shows on either face, but is placed at or near the centre of the wall. It should be so arranged that two successive courses of stretchers do not come vertically one above the other [see the section, 73]. Where a wall is not stopped, but is returned, the angle brick in each course must show as a stretcher in the return wall, but immediately beyond this brick the use of headers is resumed [83].

Double Course of Footings. It is a useful practice to build the lowest course of footings two bricks high [78], and this should invariably be done if circumstances permit of the concrete bed being omitted. This is sometimes done for all courses [78] where the loads are heavy and the foundations deep enough; but though advantageous when great strength in the footings is required, this doubles the depth of the footings and naturally adds to the cost. Any course of footings that is formed with two courses of bricks will show ordinary English bond, a course of headers above a course of stretchers on the face.

Marking the Line of Footings. In laying the bricks after the angles have been fixed a line is stretched to mark the inner and outer face of the wall; this is fixed at each end to an iron spindle having a blunt blade. The line can be wound round the spindle to shorten it, or unwound to lengthen it, as required, and the blade is inserted into a joint ; this line is tightly strained, and marks the level of the top of the course. When these preparations have been made a layer of mortar is spread upon the concrete bed which, if it has got thoroughly dry, should be first wetted, to prevent undue absorption of the water in the mortar. Starting from the angle brick, some mortar will be plastered on the side of it, and the next brick will be laid on the mortar bed a short distance from its final position and then moved into position, thus forcing up a little mortar into the vertical joint.

The front row of bricks on each face is first completed, and, when it comes to filling in the last brick before the next angle is reached, a little mortar is usually spread on it to form the last vertical joint. This outer row of bricks is carefully adjusted to the line, and may be tested with a level [34, page 1951]. The bricks are knocked down to their proper level with the side or with the butt-end of the handle of the trowel. The outer line of bricks being carefully placed, the filling in may proceed much more rapidly, as the same care in aligning the bricks is not necessary.

Flushing up the Joints. When the course is complete it will be found that the vertical joints on the face are filled, but that many of the other vertical joints are still open. Mortar is spread over the top of the course and worked into these joints with the trowel, and it is important that these joints should be well filled to ensure the full strength of the wall being attained and, in the case of walls above the ground level, to prevent rain being driven through the walls at imperfect joints. This process is described as *flushing up.*

The next course of footings is set out in a similar manner, being formed one-quarter brick within the line of the first until the top course of footings is completed.

Commencing the Wall. The next course of bricks forms the *base* of the wall, and at this point a slight variation in procedure begins. The courses are no longer diminished in width, but the wall is continued upwards of the same thickness for at least several feet, and the bonding has to receive attention. Instead of setting a single angle-brick the angle of the wall is raised for several courses at a time [84], and is very carefully put together. Such an angle is usually formed so as to extend at the base for a length of two or three bricks in each direction, each successive course being reduced in length as required by the bond.

Plumbing the Angles. At the angle the plumb rule is used on both the front and the return face to ensure that the quoin, or angle, is perfectly vertical. The plummet consists of a straight-edge with parallel sides [33, p. 1951], and with a fine line or groove marked on the face. At the top are two or three fine slits, by means of which a line may be readily attached and adjusted. This line carries a heavy plummet of lead at its lower end. In using this instrument one edge is placed in contact with the wall to be tested, the face of the straight-edge is inclined slightly forward, the side being still in contact with the wall, so that the line and plummet swings out a little from the straight-edge. If, when it is allowed to swing back, it falls so as to coincide with the line, it shows the edge, and, therefore, the wall with which it is in contact, to be truly vertical ; if it is not so, the bricks must be adjusted until this result is obtained on both faces. When two angles have thus been built, the line is strained through for each course, and the wall between the angles is brought up to the height to which the angles have been built, when the process is again repeated.

Building to a Fair Face. The process of forming the face of a wall carefully in this manner, so that all the exposed faces of the bricks are in an even plane, is termed building to a *fair face.* Such a length of wall is usually worked from the two ends towards the centre and from both faces, one bricklayer standing outside, the other inside, the wall, unless overhand work has to be resorted to. [See page 1171.]

Keeping Perpendiculars. Owing to the slight irregularities in the sizes of bricks, and to the possibility of slight unevenness in the thickness of vertical mortar joints, it happens, even where bond is properly formed, that unless special care be taken the vertical joints in one header course, for example, will not coincide precisely, though they will approximately, with those two, four, six or more courses below. There may be no such discrepancy as to interfere with the soundness of the wall, but its smart and workmanlike appearance is affected, and in all high-class work the bricklayer is expected to see that *perpends are truly kept* [46, page 2171]. This necessitates that from its base, or, at least, from any plinth course, the bricklayer must set out all openings that may occur in the upper part of the wall ; where these involve forming small piers with, perhaps, the introduction of a header in alternate stretcher courses to give the required dimension to the pier. This treatment must be followed in the lower part of the wall before the window openings are reached. The closers for bonding the small intermediate piers do not appear in the unbroken wall below the level of the openings, but all other perpends should be carried down. If two successive storeys in a building are separated by a moulded string or projecting band, the line of perpends may be interrupted at such points if necessary.

Thickness of Walls and Reducing the Thickness. In constructing a high wall comprising several storeys it is not necessary to carry it up of uniform thickness throughout. In London the minimum thickness of any wall at its base and the extent to which the thickness of upper storeys may be reduced is regulated by the London Building Act, 1894, Schedule 1. The thickness at different levels depends partly upon the class of structure, partly upon the height, and partly upon the

FOOTINGS, DAMP COURSES, HOLLOW WALLS, AND TIES length. These schedules give all necessary particulars, and though the regulations are not binding, except in London, they serve as a useful guide for reference in other districts in which such particulars are not prescribed by the local building regulations.

The external face of a wall is, as a rule, built throughout in the same plane, but where the thickness of the wall may be decreased it is done by omitting at definite stages one half-brick of the thickness [85]. Such a reduction is termed a *set-off*, and in most cases occurs on the inner face at a point where a floor is to be carried, advantage being taken of the ledge formed by the set-off to support the floor. In the case of a party wall this reduction is made on each side and amounts to 2¼ in. Sometimes, for convenience of carrying the lowest floor of a building, a set-off is required just above the base of the wall, and to form this an extra half brick is added to it at the base; but if this be done it is not necessary to increase the width of the footings; this thickening ranks merely as extra brickwork to carry the floor, and is built up so as to include in its thickness the two top courses of footings [72].

Sleeper and Fender Walls. It is often convenient and economical to form dwarf walls between the main walls to help to support the lowest floor, and such walls are termed *sleeper walls*, because they carry a wood sleeper or plate, which in turn carries the floor joists. Such walls may be a brick or half a brick thick, and will require footings. They are often formed as *honeycomb walls* [82]—*i.e.*, every course is formed, not by laying the bricks so that the ends are joined together by a mortar joint, but by merely bedding the bricks in mortar with a considerable interval between the ends; stretchers only are used. The objects of this construction are partly economy of material, but mainly the promotion of free ventilation below the floor level; such a wall is, of course, less strong than an ordinary wall, but it is amply strong for a low wall subjected only to a vertical load; it is rarely more than eight or ten courses high. *Fender walls* are usually one-brick walls built in front of a fireplace on the lowest storey, to carry the hearth-stone and the floor joists.

Damp Courses. At some point above the base of the wall and below the level of the lowest floor it is necessary to insert in all walls, including sleeper walls, a layer of impervious material to prevent moisture from rising in the walls. The footings, and perhaps the wall itself for some height, are usually in contact with the soil, and, being absorbent, will take up moisture from it; and this will, if not interrupted, tend to spread upwards and render the brickwork damp. This layer of material is termed a *damp course*, and, obviously, must, to be effective, be placed at such a level that at no point above it will the natural earth be in contact with the wall. The wall is carried up to the required height, and finished off with a level surface to receive the damp course, which may be of various materials.

Mineral Asphalt Damp Course. Probably the very best material in the British climate consists of a layer of *mineral asphalt* ½ in. thick. The only possible drawback to this material is that, if subjected to a high temperature, it may soften and ooze out under the pressure of the walls above it. It is laid in the following manner. For the best work, after the brickwork is levelled, the mortar or cement should be allowed to get fairly dry; thin slips of wood are fixed on each side of the wall, so as to stand ½ in. above the bed; the asphalt is melted in a cauldron, and becomes semi-liquid, and is then, while still hot, poured over the wall and the top is levelled; the material cools rapidly and becomes hard. It should not be laid on wet mortar, as steam is apt to be generated, and small bubbles formed. The wood edges are not always used; the material is so thick that it can be worked up to the edge as it cools without running over, but there is more liability to unevenness in thickness. One great advantage of this material is that should there be any change in the level of the damp-proof course, it may easily be worked on to the vertical surface between such different levels.

Other Damp Courses and Materials. Another excellent damp-proof course is formed of blocks of *highly-glazed terra-cotta* or *earthenware*. These are manufactured of different widths, so that in walls of moderate thickness each slab extends through the full thickness of the wall. These slabs are usually 3 in. thick, and are perforated horizontally by a series of openings so as to form a ventilating course also. They should be laid on a bed of Portland cement, mixed with a little sand, and the vertical joints formed in the same material, and should have a similar bed above them. It may be noted here that where the expense can be properly incurred it is very desirable to construct the footings and the lower part of the wall up to the damp course in cement mortar. *Sheet lead* is sometimes used as a damp course bedded in and covered by a layer of cement. One of the most usual forms, and a very economical and serviceable one, consists of two layers of good, impervious roofing slates laid on and between cement beds, and so placed that the joints in one course of slate break joint with the other course. Any of these are reliable, but care should be taken after they are laid to protect them till they are covered with brickwork. A mixture of tar and sand is sometimes used, but is liable to soften and squeeze out if the wall is exposed to sunshine even in this climate. Felt is quite unreliable as a damp course; after a time, if constantly subjected to the action of moisture, it is likely to perish.

Floors Below the Ground Level. It not infrequently happens that it is necessary to place the lowest floor of a building below the level of the ground surrounding it. When this has to be done the best course is to provide outside the wall an open area 3 ft. wide or more if possible [77], so that the wall is nowhere in contact with the surrounding earth. The level of the floor of this area must be taken down sufficiently low to bring it below the level of the

damp course. But in many cases circumstances do not permit of this treatment, and some other means must be adopted.

A *dry area* [75] is sometimes formed by building a thin outer wall 4 in. or more from the main wall; the bottom is carried down below the level of the damp course, and provided with a channel or drain to dispose of any moisture that soaks in through the outer wall; the top is covered with stone slabs or brick arching, and openings are left at intervals to provide ventilation to the space between the two walls. The outer wall may absorb moisture from the soil and become wet, but the damp cannot pass directly to the inner wall; such a narrow area is difficult of access, and not entirely satisfactory. Where no open or dry area can be formed, a damp course placed above the ground level, though it will keep the walls above dry, will not protect the lower part of the walls, and in such a case there must be a second damp course below the floor level, and provision must also be made for preventing moisture soaking into the wall between these levels.

Vertical Damp Course. A vertical damp course may be formed by covering, or *rendering*, the outer face of the wall with a layer of Portland cement and sand about an inch thick, or covering it with asphalt, which is best put on in two rather thin coats, say ⅜ in. each. A better plan still is to provide such a layer of asphalt in the thickness of the wall, where it forms a vertical damp course and is secure from any damage or interference [76]. This involves a straight joint in the thickness of the wall; but the disadvantages of this may be obviated by the use of bonding irons or ties to bind the two thicknesses together. The best method is to build one part of the wall first, building in the iron ties, which are galvanised, at intervals of 1 ft. 6 in. in every fourth course; the face of the wall is then covered with asphalt, leaving the outer end of the irons protruding from the face, and these are built in to the other.

thickness of the wall as it goes up. Such a wall is perfectly sound and entirely proof against damp, even in the case where the ground is actually waterlogged, and may be used in forming storage tanks for water.

Another method is to build the two parts of this wall with a considerable cavity, say 1½ or 2 in., and to fill in this cavity with such a material as hygienic rock, which is a damp-proof material somewhat similar to asphalt; it is filled in hot into the cavity, and is impervious. If this be done the operation should be carried out at intervals of about four courses; if the cavity be allowed to become deeper than this before it is filled in, there is some risk of air bubbles being formed in the material, which may then fail to keep out moisture.

Hollow Walls. For buildings of a small class, walls of one brick thick are allowed by law and are sufficiently strong; but they are not thick enough in an exposed situation to keep out wet if accompanied by driving wind. In some situations even a brick-and-a-half wall built in cement will hardly do so. For such positions hollow walls are frequently employed; these are formed throughout their height of two walls of brickwork, between which is a cavity varying from 1½ in. to 3 in. [79]. In some rural districts walls are permitted to be built 9 in. thick in this way, the bricks being used on edge instead of flat, and built as Flemish bond, the headers forming the tie between the inner and outer skins of brick. Such a wall is ugly in appearance, but would be likely to resist the weather better than an ordinary one-brick wall. As a rule, such a wall would not be allowed in any urban district, certainly not in London, and is, in any case, only suitable for work of no great height and requiring no great strength. As a rule, a hollow wall is built with an inner thickness of at least one brick and an outer thickness of at least a half brick, and the two are bonded together at regular intervals by some special form of tie.

Wall Ties. These may be of glazed terra-cotta [79] or glazed earthenware, and are of such a form that the inner end is built 4½ in. into the inner wall, corresponding in height with an ordinary brick course, while the outer end is built into the outer wall at a level one course lower down. This form is adopted to ensure that, if any water should be driven through the outer thickness and reach the bonding brick, it shall be thrown back against the outer wall and not reach the inner one. The outer end, if it be built into a half-brick wall, is made only 2¼ in. long, and will have a quarter-bat in front of it to correspond with the wall facing. A cheaper and more usual form of tie is made of galvanised iron, cast or wrought; the latter are the better. They are made with fangs at each end for building into the two walls, and the part corresponding to the hollow space is formed with a dip or twist to ensure that any water will drop from it and not pass across the tie to the inner wall.

Constructing the Hollow Wall. Such a hollow wall should start from the level of the damp course or below it and extend above the top ceiling. A channel should be provided at the bottom to carry off any water collecting in the hollow [74], and great care must be exercised to see that in building the walls the mortar is not allowed to drop into and choke this channel or to lodge upon the ties; it is best to have openings in the outer wall at intervals at the level of the channel so that it may have any such mortar droppings removed on the completion of the wall.

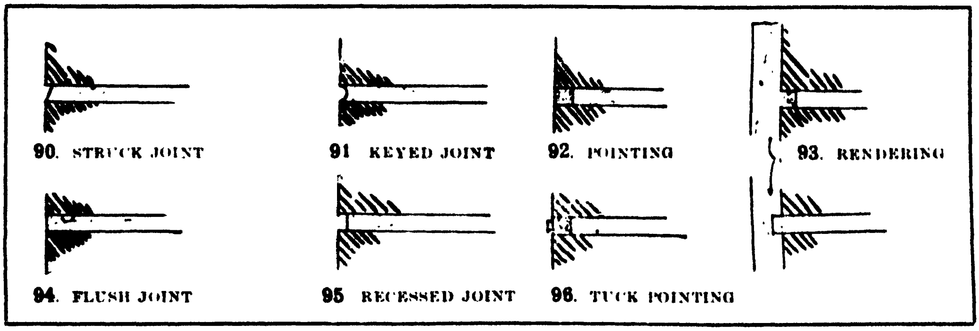
Air Bricks. Ventilation must be provided to this space by means of air bricks built at intervals into the outer wall near the bottom of it and also near the top; these are usually 9 in. by 3 in., or 9 in. by 6 in., and may be made of brick earth, with a series of perforations passing right through, to allow of the passage of air, or they may be of cast iron. In the latter case they consist of a cast iron box of the thickness of half a brick, with an external plate of iron perforated to admit air [80 and 81].

Openings in Hollow Walls. When openings for doors or windows occur in such a hollow wall, the hollow space may be stopped at the jamb with narrow slates set in cement; wherever the heads of timber frames or wood or concrete lintels run across the hollow, the upper surface must be protected by a small gutter of lead or zinc turned into a joint in the outer wall and long enough to project beyond both ends of the member to be protected, so that any water may be discharged into the hollow space clear of any timber [86].

Upper Part of a Wall. In constructing a wall, the outer face is generally a perpendicular one, and is built throughout in a single plane, but there are likely to be, at certain points, various departures from this plane face. In the first place, just above the ground level, the face of this wall is sometimes set back, not by means of an offset, but by means of a moulded or splayed surface. Such a projection at the base of the wall is termed a plinth, and in a brick wall is usually 2¼ in. or 4½ in., but sometimes much more. Their moulded face may be of brick, or of stone, or terra-cotta [18, page 1947; and 70, page 2177], and, in any case, is built into the wall as the work goes up; if stone or terra-cotta be used, the course must be arranged to bond with the brickwork, as already described.

Forming String Courses. At higher points in the wall, bands of mouldings, termed string courses, may be built in so as to project beyond the face of the wall, and may be of brick, stone, or terra-cotta, arranged so as to bond with the brickwork. In addition, it usually happens that the upper surface of such a string course, if it be of brick, will be horizontal, and as there will be many joints, water is likely to lie in the top and find its way in. To obviate this, either the top is covered by a strip of lead, turned up against the wall above and into a brick joint, or the surface is covered with a layer of Portland cement mixed with sand, the upper surface of which is inclined, or *weathered*, so as to throw any water away from the wall; this is termed a *weather fillet* [87]. Any horizontal upper surface of brickwork that has to be formed should be so protected.

Corbelling. It may often happen that it is desired to project a portion of the upper part of a wall beyond the lower so that its face overhangs the lower part of the wall—*e.g.*, such a projection is often formed to provide the extra thickness required to form the fireplace and flues of an upper storey. This may be done in brickwork by *corbelling* or *oversailing* **[88]**, which consists in projecting successive courses of brickwork so that the face of each slightly overhangs the face of the course below—exactly reversing the arrangements of footings. No single course should project more than 2¼ in. beyond the course below it, and for many purposes a projection of 1⅛ in. is more satisfactory. In the former case, four courses, and in the latter eight courses, will give a projection of 9 in.



METHODS OF FORMING BRICK JOINTS

In cases where the upper part of a wall is to be rough cast or hung with tiles, the lower part of this wall is usually finished with two or more courses of corbelling so as to throw out the lower edge of the tiling or rough cast **[88]**. Such a corbel course may be formed of plain or moulded bricks, or of a mixture of plain and moulded bricks. Where each course projects 2¼ in., it is desirable to use header bond, but with a projection of 1⅛ in. stretcher courses may be used.

Cornices. Sometimes at or near the top of a wall a large and elaborate group of mouldings is corbelled out from its face, and in this position the term *cornice* is given to such a feature, which is an architectural enrichment, and not essential to the structure **[87]**. Such a cornice may be formed of brick, and will include courses of plain as well as moulded, and very possibly enriched bricks. When formed of such small material, great care is required in putting together such a cornice, the corbelling out of which must be carefully done. The upper surface must be protected by leadwork or cement, and the wall is often carried up beyond the top of the cornice, forming a blocking course, to counteract the tendency of such a feature to overbalance. Any cornice of brick must be designed to be of only a moderate projection, and cannot overhang to the extent that is possible with one formed of long stones.

Protecting the Top of a Wall. The top of any wall requires some special care to ensure that water shall not lie upon it and soak into it. In some buildings the top of the wall is completely covered by the roof which overhangs it, and so far as protecting the wall is concerned, no better plan is possible. But in towns such an overhanging roof is often not permissible, and the roof must finish behind the wall, or, if it covers part of the wall, a thickness equal to one brick at least, is carried up, and is termed a *parapet* [**16**, page 1949]. In either case the top must be protected so that rain falling upon it will not soak in. An inexpensive and effectual method is by forming a *tile creasing* at the top. This consists of laying on the upper surface of the wall two or more layers of hard, impervious roofing tiles so as to overhang both faces of the wall. These are laid in cement, so as to break joint, and, in fact, form a damp course at the top of the wall; they are usually finished by a course of plain or bull-nose or half-round bricks set on edge and built in cement. Such a course of bricks forming the termination of a wall is termed a *coping course*.

Special Copings. For rather better work brick or terra-cotta copings of special design [**17**, page 1949] are made in large blocks so as to reduce the number of joints, and so as to overhang both faces of the wall, and a hollow should be formed in the under surface of such a coping block on both sides of the wall, so that any water running from the upper surface shall drip from the edge of the coping and fall clear of the wall, and not drip down the face of it; such a hollow is called a *throat*.

Copings are made in a great variety of forms and widths to suit different styles of architectural treatment and individual tastes. In some the water is thrown off one edge of this coping, which is then styled a *weathered coping*; or, if a plain surface be formed to throw the water off both edges, it is termed a *saddle-back coping*, and others are termed *moulded copings*.

Finish to Ramps and Sloping Surfaces. A curved surface forming the top of a wall in such a feature as a ramp must have the bricks cut to the required form, but is usually finished with a coping of brick on edge which, if the curves are sharp, must be axed. This is to avoid finishing the top of a wall with small pieces of cut brick, which would easily be displaced, and the cut surfaces of which would be particularly liable to absorb moisture. Where the width of an external feature, such as a chimney stack, requires to be reduced, simple offsets are both ugly and unsuitable, and such reductions may be made by forming a double slope across the thickness of the wall with a small gable covered with tiling or a coping, or by a single slope finished by what is described as *tumbling;* this consists of a series of brick courses set at right angles to the slope, and the lower surfaces cut to fit on to a horizontal bed, the object being, as in the case of a ramp, to show only whole bricks on the exposed surface.

Effect of Heat on Brickwork. If brickwork be executed in very dry or hot weather the bricks themselves will be dry; if laid in this condition they are likely to absorb the water from the mortar to such an extent as to interfere with the action of setting, and at such times the bricks should be well wetted before use. This is best done with a hose before they are carried to the scaffold.

Effect of Frost on Brickwork. Brickwork in mortar should not be executed during the prevalence of frosty weather, the danger being that the water in the mortar will be liable to freeze. In Norway it is held that with due precautions brickwork may be safely carried on when the thermometer stands at 14° to 18° F., and even when it is as low as 0° F., but that it ceases to be economical when the temperature is below about 14° F.

At these temperatures work is executed with mortar mixed with quite freshly-slaked lime made in small quantities and used while still hot, and the proportion of lime is increased as the temperature becomes lower, so that setting may take place before freezing. The bricks must be quite dry when used. Bricks exposed to rain or frost must not be employed, and after any temporary stoppage of work the top of any piece of brickwork must be cleared of any ice or snow before work proceeds. When the frost is not severe, work may usually be carried on in cases where a quick-setting cement is used.

The top of a wall may be protected during frosty weather by covering it with felt or sacks and boards; the mortar joints may be affected for some little distance into the wall, and must be then raked out and pointed, but if the damage extends far into the wall the only remedy is to take down and reinstate the work.

Finishing Mortar Joints. The mortar joints on the face of the wall may be finished in various ways, but they are rarely left just as they are formed in laying the bricks. If the surface of the wall is to be plastered or rendered [93], the mortar in both horizontal and vertical joints is raked out for a depth of about ¾ in.; this is to give a better hold or *key* to the plaster. If the face of the wall is to remain exposed, the joints are carefully finished, and this process greatly improves the appearance of the brickwork. If the weather be suitable, this may be executed as the work proceeds, and the joints are then said to be *struck* [90]; if the work is of such a nature that it can be completed in this way without fear of frost, it gives good results. Where frosts may be expected to occur before the walling is complete, it is usual to rake out the joints to a depth of about ¾ in. as the wall is built, and to finish the whole face of the wall when completed, and this process is termed *pointing* [92]; it involves reinstating the stages on the scaffold to carry out the work better than is necessary for merely making good the putlog holes, and the work must be well wetted before pointing. In the case of old walls, in which the mortar joints show signs of decay on the surface, this method is always employed.

The actual finish of the face may be made in a variety of ways, and many of these may be used whether the joints are struck or pointed. The joints are actually formed with the trowel. A special small trowel is sometimes used, and a long straight-edge.

Flat, or Flush Joints. *Flat,* or *flush* joints [94] are those in which the mortar is flush with the face of the wall and vertical; this is sometimes varied by leaving a line drawn along the centre of the joints by means of an iron jointer.

Struck Joints. *Struck* joints [90] are formed with an inclined face; the lower edge is flush with the brick below and is struck with the trowel and straight-edge; the upper edge is pressed back so that any water dripping from the brick above will be thrown off by this surface on to the face of the brick below; this form of joint is sometimes described as a *weathered joint.*

Keyed joints [91] are formed by drawing a rounded iron along the centre of a flush joint, giving it a hollow section.

A *recessed* joint [95] is formed by setting back the face of the mortar behind the face of the brick; but this is not so good a protection to the wall as a weathered joint.

Tuck pointing [96] is generally used to conceal the defects of inferior work. The joint is filled flush with mortar; the wall is then rubbed down with a soft brick, so that the bricks and mortar are of a uniform colour, or a wash of ochre is sometimes applied; finally, a fine line of white putty is worked on to the centre of the surface of the joint, so as to give the appearance of gauged work.

Forming Toothings. If for any reason a cross-wall cannot be built at the same time as the main wall from which it starts, a *toothing* is formed in the main wall—*i.e.*, in every alternate course a recess the full width of the cross-wall and 2¼ in. deep is formed by building in the closers used to bind the cross-wall only. This allows of the cross-wall being properly bonded to the main wall when it is built, but unless the walls are built in cement the main wall will have settled down slightly before the cross-wall is erected, and this, too, when built will in time settle down also, and a fracture at the joint may result.

If a new wall has to be bonded to an old one it is usual to cut out toothings the full thickness of the new wall three or four courses high, and penetrating 4½ inches into the old wall, and to build the new work into them.

By A. J. WINDUS

ALL systems of accounting have for their common object the recording and classifying of transactions, and this is equally true of single-entry as of double-entry methods. In double-entry, analysis and synthesis are the vital processes, but in single-entry systems analysis is not an active principle but an accidental circumstance, and therefore any classification obtained by single entry is seriously defective.

By synthesis is meant firstly the building up of items into accounts, and lastly the consolidation of open accounts into a few great classes in the Balance Sheet. There are also intermediate stages which will claim our attention.

What We Understand by Analysis. By analysis we understand the resolving of transactions, accounts, items, totals, into their constituent parts for the purpose of forming fresh combinations or of deducing other information than what appears on the surface. Thus, the total of the "Paid" column of the petty cash book, at page 403, is broken up into various sub-totals, so that in place of one set of figures amounting to £89 13s. 11d. we have six new sets or combinations to deal with. Again, in double-entry systems, to register a transaction it is necessary to analyse it—that is, to discover the debit and credit elements of which it is composed—before entering it in a specialised book of original entry or in the journal.

Goods Bought on Credit. In single entry, however, this rule is "more honoured in the breach than in the observance," for we usually find but one aspect of a transaction noted. Thus, where goods are bought on credit some persons adopt the free and easy method of making entries straight from the invoices to the creditors' accounts in the ledger, and imagine that a saving of time is effected thereby. But if short cuts are to constitute the sole test of merit in bookkeeping, then the most summary way of dealing with the matter would also be the best—namely, to refrain from opening any accounts at all with creditors. As the monthly statements arrived they would be compared with the invoices already passed, and, if correct, cheques or cash would be remitted in settlement; if incorrect, explanations would be asked for.

Everyone knows that, were such a course adopted, two of the principal objects of bookkeeping—to furnish information as to the financial condition of a business, and also with regard to its progress—would be defeated. Few single-entry bookkeepers go to this extreme, and yet the methods of the rest are scarcely more efficacious in tracking the *progress* of an undertaking than the policy of inaction pursued by the minority.

The Invoice Guard Book. Many single-entry bookkeepers use an invoice guard book similar to the order guard book [described on page 776], as the medium for posting invoices to the ledger; but all of them stop short of double entry, which is frequently confounded with double posting—it being supposed that every invoice must first be posted to a creditor's account, and then to some other account, so that if there were two hundred invoices there would be four hundred postings. Of course, the only thing necessary to complete the double entry here is to ascertain the grand total of the invoices as posted from the guard book, or from the invoice journal, and to post this total to the debit of some account in the ledger representing goods.

There is one objection to the use of guard books which might easily be removed, since it grows out of the absurd practice of crowding the invoices due to an exaggerated sense of the value of space. It is usual to secure invoices in the guard book by means of "stickphast," gum, or some other adhesive substance, and to fold them to a uniform size in much the same way as letters received are folded for filing away in pigeon-holes. Thus, from half a dozen to a dozen invoices may be accommodated on a single page of the album; but the irritation and loss of time occasioned by having to unfold invoices when required for reference outweigh the paltry economy of space achieved.

How the Guard Book Should Be Used. It has been sought to mitigate the annoyance by endorsing upon the outside of each invoice certain particulars as date, name of creditor, and amount, but although this plan facilitates reference it entails labour which might be avoided. The remedy consists in fixing the invoices into the guard book and leaving them unfolded, the second invoice being placed immediately below the first or on the next page, should the first happen to take up too much room to allow of a second being affixed beneath it. The third invoice would follow the second, and so on. The guard book would have to be renewed more often under this plan than under the old method, but a book of 500 or 1,000 pages would be ample for a year's invoices in the majority of cases. Moreover, where the books are kept by double entry and an invoice journal as well as a guard book is used, the invoices in the latter may be so arranged as to overlap one another, but without interfering to any appreciable extent with ease of reference. In such a case, only the lower border of the back of each invoice is gummed to the guard book, the second invoice being affixed at a sufficient distance below the line of adhesion of the first to ensure that the unattached portion does not cover up the *heading* of the invoice which it overlaps.

Filing Invoices in Guard Book. Invoices are filed in the guard book in alphabetical order at weekly or other intervals, and from thence are entered into the invoice journal. On each invoice is noted in red ink or blue pencil—black ink does not show up well—the folio of the invoice journal on which it is entered, and in the journal is noted either the page of the guard book where the invoice itself is to be found or the serial number given to the invoice upon its being passed for filing and entry.

The using of a guard book without an invoice journal is not necessarily incompatible with the principles of double entry. In some wholesale houses the guard book is elevated to the dignity of a journal. On every page a money column is provided into which the invoice amounts are extended, each amount being exactly opposite the total of the invoice to which it relates. The various invoices are posted separately from the guard book to the ledger, and the double entry is completed by posting the total of the money column to purchases account in the ledger.

By reserving a separate guard book for each department of a business a second and closer analysis of the transactions represented by the invoices is effected. In lieu of one grand total for purchases during a given period, we obtain as many guard book totals as there are departments; and the information will be of service when inquiry is made as to which departments are responsible for profits, and which for losses, and the extent to which the different departments have contributed thereto.

Where but one invoice journal or guard book is kept for all departments the analysis in the first instance merely resolves the invoice transactions into their debit and credit elements, there being one debit to purchases account (or goods account) as against a number of credits to the sellers of the goods.

Analysis Columns in the Invoice Journal. To distribute purchases over the various departments of a business, so that each department shall be charged with the goods it receives into stock, the original analysis must be supplemented by a further dissection, for which purpose analysis columns, similar to those in the analysis petty cash book, are sometimes inserted in the invoice journal, each column being headed with the name or number of a department. In other instances, dissection sheets are resorted to. These will be explained in due course.

It is doubtful whether, in view of the modern tendency to discard bound books in favour of loose-leaf books, card systems, and the like, the guard book will long survive the attacks made upon it. It has, however, justified its title by guarding the documents entrusted to its keeping, and while capable of improvement in some respects, it excels in others.

Trading Account. Students may find it useful to refer to our previous remarks upon the treatment of invoices [see page 977], after which let us consider the following transactions as they appear in the synopsis at pages 1750 and 1751—namely, (*c*) to (*g*) inclusive, (*t*) and (*u*). It will be observed that they all relate to goods, some to purchases—(*c*) and (*t*)—some to sales—(*d*), (*e*), (*f*), (*g*)—and one to returns (*u*). Formerly, bookkeepers recognised no other classification for such transactions than that of "goods" or "merchandise," but the normal development of the analytic method has changed all that, and the primitive goods account is now broken up into several sub-accounts, which are periodically united under the title of Trading account.

This departure from ancient custom indicates that the old method has been tried and found wanting. Let us see why the Goods account stands condemned at the present day. The theory upon which it was constructed was simple enough, and was derived from the fact that the chief business of a trading concern is to buy goods and to sell them at a profit. It was argued with some show of reason that if one account were opened, and debited with all goods coming in and credited by all goods going out during a given period, and if at the end of that period this account were also credited or discharged by the value of the unsold goods or stock on hand (if any) *at cost prices or under*, and a balance struck, then the amount by which the credit side of the account exceeded the debit side would represent profit—not ultimate or *net* profit after all expenses had been paid, but great or *gross* profit on the goods actually sold, minus any loss which had occurred by depreciation of the goods remaining unsold. In like manner, the amount by which the debit side of the account exceeded the credit side would represent loss—not final loss after all expenses had been paid, but the initial loss on the goods actually sold, plus any loss which had occurred by depreciation of the goods remaining unsold. Depreciation, it may be added, has to be reckoned with whenever stock is become shopworn, unfashionable, or obsolete, or whenever it has suffered damage or deterioration such as renders it unsalable except below cost, when it may truthfully be said to be offered "at a sacrifice." In the latter case, the probable extent of the loss when the goods are sold will be the measure of depreciation in the stock of those particular goods.

The Goods Account. The proof relied upon by the old-time bookkeepers to establish the foregoing theory will now be given, and its limitations explained. This will enable us to understand why the goods account has been discarded by the modern accountant.

Mr. Andrew Crawford, of Liverpool, is the patentee of a portable heating and cooking apparatus which he desires to introduce to the public under the trade name of the "Triumph" oil-stove. He decides not to risk his capital in building a factory and in laying down a suitable plant for making stoves of this description until evidence is forthcoming that the article has obtained a firm hold upon the public favour. No surer testimony to the existence of a genuine demand for an article can be found than that supplied by the steady increase in the sales of that article, season by season and year by year, and this is the evidence Mr. Crawford requires before embarking upon a course of action which would necessitate a large outlay of capital.

But if he will not make the stoves himself he must procure someone to make them for him. He therefore enters into negotiations with the Birmingham firm of Jones, Price & Co., hardware manufacturers, who undertake to supply his wants upon mutually satisfactory terms. The contract between the parties as finally drafted provides, among other things, (*a*) that Messrs. Jones, Price & Co. shall manufacture "Triumph" stoves exclusively for the patentee and to his specification; (*b*) that the patentee shall order from the manufacturers a minimum number of such stoves during the currency of the contract—that is to say, within a period of three years from its initiation—and shall have the right to order as many stoves above such minimum number as he shall require; (*c*) that a fortnightly delivery of stoves to the patentee shall be made at the rate of not less than a specified number per annum; (*d*) that the price per stove delivered at the patentee's warehouse in North John Street, Liverpool, shall be 8s. 6d. for size A, and 11s. 4d. for size B; (*e*) that statements of account shall be rendered monthly, and that same shall be subject to 3¾ per cent. cash discount if paid within 10 days from the date thereof.

Gross and Net Profits. So far, then, as goods coming in are concerned, Mr. Crawford is in the position of a wholesaler, but he has now to make up his mind whether he will attempt to reach the public direct or through the retailer. If he decides in favour of the latter, and perhaps the wiser alternative, he will have to be content with a somewhat smaller rate of gross profit, because the retailer is also entitled to a profit, and usually obtains a higher percentage of profit than the wholesaler. If "Triumph" stoves were offered to the public at exorbitant prices, there would be an abatement, or possibly a total cessation, in the demand for them. Generally speaking, a small turnover with a high rate of gross profit is not so good as a larger turnover with a lower rate of profit. Take the case of a retailer who has been making 33⅓ per cent. "on returns"—that is to say, on an average the cost price of each £150 worth of goods sold is £100. On sales amounting to £3,000 the gross profit would be one-third of that sum, or £1,000.

Let us assume that the conditions were such that the profit of £1,000 provided a sufficient margin out of which to pay fixed expenses, or establishment charges, as rent, salaries, trade expenses, and the rest. The residue, after the whole of these expenses had been met, would be styled "net profit," and would belong to the proprietor.

Reduced Rate of Profit. Suppose, now, that the retailer determined to make a bid for an increased volume of business by lowering his prices somewhat, so that, instead of securing on an average 33⅓ per cent. gross profit, he obtained 25 per cent. only, and that, largely owing to this stimulus, the second year's turnover was double that of the first year. What has happened? In the first place the sales have grown from £3,000 to £6,000, and the gross profit from £1,000 to £1,500. But it may be asked: "Is not this additional £500 swallowed up in extra expenses?" Not unless there has been mismanagement or dishonesty. It is a law of business—the persistent violation of which invariably ends in disaster—that establishment charges must increase at a smaller ratio than the sales in respect of which they have been incurred. On this basis it is clear that, allowing for a slight natural increase in the fixed expenses, due to an increase in the sales and to other causes, the retailer would still be better off when he was getting 25 per cent. on a turnover of £6,000 than when he was earning a higher rate on a lesser volume of business.

During the first year of his contract Mr. Crawford took delivery of 5,732 A "Triumphs" at 8s. 6d., and 1,476 B "Triumphs" at 11s. 4d. His credit sales throughout the same period were 5,432 A stoves at 10s., 1,419 B stoves at 13s. 4d.; 217 A stoves and 140 B stoves were, however, returned by customers for various

reasons, and 79 stoves (28 A and 51 B) were sent back to the factory as being defective. There were no cash sales. With these facts before us we can exhibit the goods account in an abbreviated form, but it should be borne in mind that the account here given is not a copy, but a summary of the account in Mr. Crawford's ledger.

The goods account is here shown in condensed form, but Mr. Crawford has adopted the detailed form which, at much greater length, supplies less real information. For every purchase, a journal entry is made debiting goods account and crediting Jones, Price & Co., and for every sale the customer is debited and goods account credited. Conversely, for returns to factory (returns outward), J. P. & Co.'s account is debited and goods account credited; for returns from a customer (returns inwards) goods account is debited and the customer's account credited. This is double entry with a vengeance! The number of items on the credit side of goods account may be gauged from the fact that in the first year of trading 249 accounts have been opened with retail ironmongers and others. Furthermore, a great many customers have sent "repeat" orders, so that there are probably not less than six or seven hundred postings to goods account on the credit side alone. The debit side is briefer, since it relates chiefly to purchases from Jones, Price & Co., who despatch and invoice goods to Crawford fortnightly, as per contract.

In a goods account built up item by item, not only are time and space squandered as the direct result of the method employed, but the account itself is perplexing, because it fails to discriminate between purchases and returns inwards on the one side, and between sales and returns outwards on the other. Omitting dates and journal folios, the goods account in Mr. Crawford's ledger would be set out as below.

Comparing this with the former goods account, marked No. 2, we observe that, despite variations in structure, the two accounts agree as to the amount of profit balance, and as to the amount of stock in hand. But the goods account has not fulfilled its office by merely disclosing the value of the stock in hand and the amount of gross profit earned; we wish also to know the *rate* of gross profit, the number and selling value of stoves sold in each month, the number returned, the total sales and purchases for the year, the ratio of returns to sales, and other useful facts about the business which are capable of being elucidated by means of the figures contained in the goods account. It thus appears that the *form* of the goods account is a matter of importance, because to be of service the information stored up in that account should be always accessible. It is a step in the right direction when specialised books of original entry are substituted for the journal, the monthly totals only of purchases and returns inwards, sales and returns outwards, being passed through the journal and posted to the goods account.

THE PRESENT & FUTURE OF TRANSIT

Public Service Automobiles. Electric Traction. Water Transit. The Marine Turbine. The Problems of Air Transit. Submarine Boats

By F. L. RAWSON

NATURALLY the principle of the automobile has been applied to omnibuses for public traffic, and strenuous efforts have been made to arrive at a satisfactory design for such vehicles. Hitherto, although a fair measure of success has been attained, it cannot be said that the difficulties have been overcome. One of the principal troubles is the cost of tyres, which amounts to 2d. per car-mile on the average—a very serious item. Many motor-'bus services have already been put in operation, although the Royal Commission on London Traffic, which reported last year (1905), did not consider that the vehicle offered a solution to the problem of rapid transit, in its present stage of evolution.

The Motor-'bus. Undoubtedly the motor-'bus will be developed into a practical and commercial success, and will in time displace the great majority of the horse-drawn 'buses at present plying in the streets. Unlike the electric tramcar, its chief rival, the motor-'bus can thread its way in and out through traffic, and is thus enabled to compete in speed with the former. Its carrying capacity (34 seats) is about half that of the tramcar, so that twice as many 'buses are needed to cope with a given traffic; but it has the great advantage that it is not tied to a fixed route, and is free from the heavy burden of capital and maintenance charges due to the costly track required for the tramcar. There is no doubt that in sparsely populated districts, where the traffic would not justify the expense of a tramway, the motor-'bus will be, and indeed already is, a most valuable means of transit; as a feeder to tramways and branch railways, it will be almost indispensable.

Prepared Tracks. Obviously the use of a carefully-prepared track for the wheels of carriages and waggons greatly facilitates progression, and, in places where traffic was particularly heavy or the gradients severe, slabs of stone, wood, or iron were laid down many years ago to secure this advantage. From this custom arose the modern tramway, or street railway, in which steel rails are laid flush with the street surface, and the vehicles are provided with flanged wheels suitable for running thereon without liability to become derailed. In order to prevent the road material from clogging the flanges and hindering progress, or throwing the wheels off the rail, the latter is provided with a lip, forming with the head of the rail the so-called groove. On such a tramway heavy vehicles can be hauled with ease, and as tramways are almost invariably employed for public service only, the vehicles are arranged to accommodate as many passengers as possible.

Horse Tramways. In the great majority of foreign countries the cars consist of a covered platform carrying a series of seats, providing sitting accommodation for from 20 to 30 passengers; in Great Britain, on the other hand, it is the usual custom to add a second tier, or deck, to which access is gained by a staircase, and the seating accommodation is thus raised to about 40 passengers. The smaller cars are sometimes hauled by a single horse or mule, but two are required to propel the larger cars, which weigh four or five tons each when empty. On horse tramways through urban districts a speed of about six miles an hour is maintained, including stops, and the charge made is usually about 1d. per mile; this sum, however, leaves very little margin for profit—sometimes none at all.

Power-driven Vehicles. For this reason continual attempts have been made to substitute a more economical means of haulage than horses. Cars hauled by small steam locomotives have been used in many places, while gas power and compressed air have also been tried, but without much success.

Cable Traction. In districts where the traffic is very dense and continuous it has been found practicable to haul the cars by means of an endless cable, traversing the whole length of the line, and running in a conduit beneath the roadway. Connection is made with the cable by means of grippers, which pass through a slot in the surface of the roadway, and can be attached or removed when desired. The advance of the times, however, has led to the abandonment of this expensive system in the great majority of cases in favour of the use of electricity as the propelling agent. Cable traction is valuable on steep hills.

Electric Tramways. Seeing that electric power has been proved the most economical, as well as the most convenient and efficient, of all mechanical tractive agents, it is unnecessary to dwell upon its forerunners. There were in November 1905, 3,100 miles of single tramway track in this country worked by electricity; almost the whole of these are operated by means of the overhead conductor system, the only exceptions being found in London, Bournemouth, Lincoln, and Wolverhampton.

In London, the County Council has equipped 26 miles of double track with the underground conduit system; in Bournemouth the corporation has adopted the same system for a length of one mile in the centre of the town, and in Wolverhampton the town council has utilised the Lorain surface-contact system, in which the cars obtain their supply of electrical energy through metal blocks laid in the street surface, projecting slightly above the latter, and connected with the electric underground cables only while the car is actually over the charged contact studs. Another surface-contact system, called the Dolter system, is about to be laid down in Torquay, and a third, the G. B. system, has just been installed in Lincoln. Obviously, however, the overhead system is the most popular, as it is also by far the cheapest to instal, and even where other systems have been used, as in London and Wolverhampton, extensions are being carried out on the overhead system.

Cost of Electric Traction. The average cost of electric traction—to the passenger—is about ½d. per mile. The speed depends upon local regulations, being generally from 8 to 12 miles per hour, including stops. In some cases, however, a speed of 14 to 16 miles per hour is allowed, and on private right-of-way the speed is limited only by considerations of safety and economy, though not usually exceeding 25 to 30 miles an hour. In America the tramways have undergone greater development than in this country, extending for many miles round and between most of the large towns; adjacent tramway systems have been linked up to form huge networks, extending sometimes for literally hundreds of miles, and very high speeds are maintained on the inter-urban lines, often reaching 50 or 60 miles per hour.

In this country the tramways are largely in the hands of the local authorities, and some of them have attained very considerable dimensions; for example, the Corporation of Manchester owns or works 150 miles of single track; Glasgow controls 147 miles, and Liverpool 103 miles. Complete through communication has been effected between many large towns, such as Leeds and Bradford, Liverpool and Bolton, Glasgow and Paisley. Naturally, the competition has reacted detrimentally upon the railway suburban traffic in many cases, in some of which the railway company has had to adopt electrical traction, while in at least one other the suburban railway service has been totally discontinued. An enormous traffic is carried on the tramways; for example, the population of Liverpool was carried 167 times over last year, that of Manchester 169 times, and that of Glasgow 196 times.

Electric versus Steam Traction. In spite of the encroachments of electricity upon the preserves of the steam locomotive, the latter still easily holds its own in the sphere of long-distance transit, and is likely to do so for many years to come. Electric traction has the great advantage that almost unlimited power can be applied to a car or train, so as to accelerate the latter very quickly, while it is also possible, with electricity, in the act of stopping, to recover a considerable proportion of the energy stored up in the moving mass. Thus, electric traction is pre-eminently adapted to cases where a frequent service is necessary, with numerous stops, conditions which are met with in urban and suburban traffic, but not at all in the case of long-distance journeys. For the latter heavy trains run at long intervals are more suitable, for the maintenance of a frequent service of stopping trains, which are necessarily slow trains, would absolutely cripple a main line express service on the same line of rails. Moreover, the cost of the complete conversion of a long line to electrical working, entailing the reconstruction of the rolling-stock and the reorganisation of the whole system of running, is at present prohibitive. Consequently, though electrical science has now made such progress that long-distance service is perfectly feasible from an engineering standpoint, it is impracticable from the commercial point of view. Progress in this direction must come by stages. In the meantime steam remains supreme.

Steam Railways. The British railway system as a whole is unsurpassed throughout the world for speed and safety; it consists of about 36,000 miles of single track, on which the average traffic is exceedingly dense. On the basis of gross receipts, the passenger traffic constitutes 43 per cent., and the goods and mineral traffic 57 per cent. of the total; the average gross receipts per mile of single track open for traffic amount to £3,100 per annum, but the traffic varies enormously, according to local conditions. For instance, the receipts per mile of track on the Central London (Electric) Railway amount to no less than £50,000 per annum, entirely passenger traffic, although the average charge is only about ½d. per mile. Owing to the constant increase in the traffic, the tendency for many years has been towards longer and heavier trains, entailing the construction of enormously powerful locomotives. It is not uncommon for a locomotive with its tender to weigh 100 tons or more, and mineral trainloads of nearly 2,000 tons are met with. In America the latter reach 3,000 tons. The adoption of corridor coaches, while greatly increasing the comfort of passengers, has also increased enormously the ratio of the deadweight to the paying weight carried, from something like 4 cwt. per passenger to 14 cwt. The average speed attained is about 30 miles per hour; express trains commonly reach 50 miles per hour, including stops, and some long-distance runs of nearly 200 miles are regularly covered at the rate of 55 miles an hour, involving the occasional attainment of speeds of 70 to 80 miles per hour. It is not likely that any material advance on these speeds will be effected with steam propulsion, but electric trains have been run experimentally at as high a rate as 130 miles an hour.

Goods and mineral trains, of course, travel at much lower rates, from 15 to 25 miles per hour. The great difficulty met with in connection with goods traffic in this country is the extremely varied character and the small quantities of the goods despatched. The average load of a 10-ton waggon is only 2 tons; the bulk of the consignments do not weigh more than 1 ton each, and an enormous number amount to only

1 cwt. Is it to be wondered at, then, that the cost of carriage within the British Isles is very high ? The cost of goods transport by rail is *studied in another part of the* SELF-EDUCATOR.

Railway Maintenance. The standard rate of charge for passengers per mile is 1d., but, owing to many causes, such as the carriage of workmen at low rates, the reduced fares for excursions, etc., the actual receipts do not, on the average, approach this figure. The working costs have risen of recent years, and now constitute about 63 per cent. of the receipts, leaving but a small margin for profit after paying interest, depreciation, etc. The average dividend paid on the ordinary capital is only 3½ per cent.

The excessive cost of running an ordinary train service on branch lines where there is but little passenger traffic has led to the adoption during the past few years of motor-cars on railways. These consist of single coaches, each of which is provided with its own propelling agency in the form of a steam or petrol engine in various modifications. By means of such cars it is possible to maintain with profit a fairly frequent service on a line that would otherwise prove unremunerative, while greatly benefiting the population of the surrounding district. The movement is still in its infancy, but is rapidly extending.

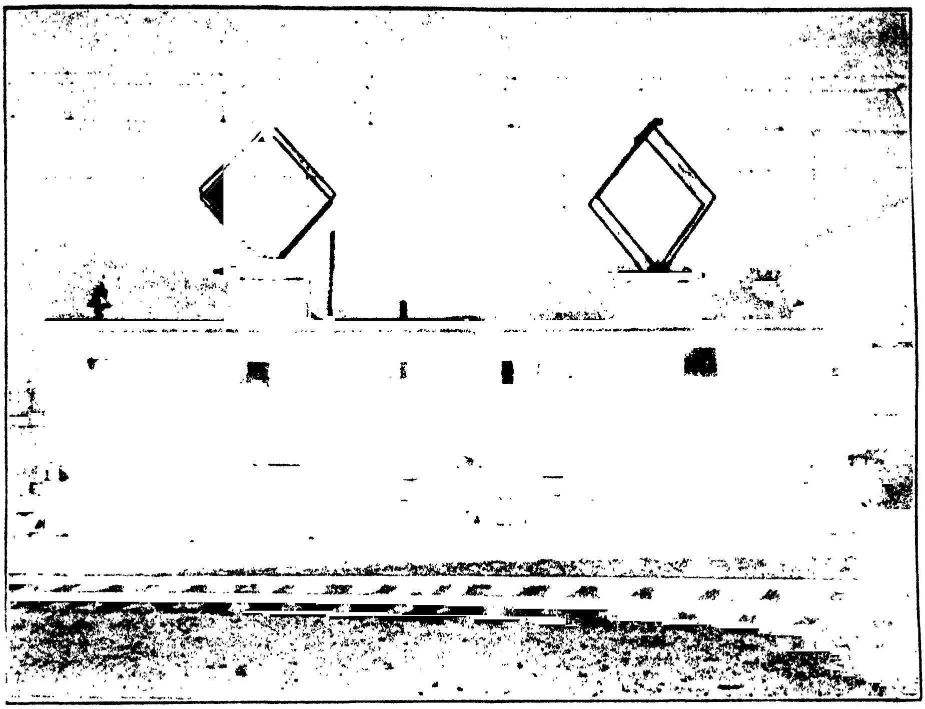
Mountain Railways. In places where the gradient is so steep that the adhesion of the wheels to the rails cannot be depended upon for hauling the train up the incline, or for controlling its speed when descending, it is necessary to adopt a positive means of driving and braking. This consists usually of a third rail in the form of a toothed rack, which is fixed to the track ; a toothed wheel carried on the locomotive and driven either by steam or by an electric motor gears with the rack, and ensures a safe grip under all conditions. Naturally the speed on such a railway is slow—only from three to six miles an hour. Many such railways are to be met with in Switzerland and other mountainous countries, where they are often used solely to enable tourists to ascend famous mountains, such as the Rigi or Pilatus, without the trouble of climbing. The only examples of rack railways in this country are on the mountains of Snaefell in the Isle of Man, and Snowdon in Wales—the former electric, the latter steam-driven. An alternative method is to haul the trains up by a cable driven by a stationary engine, but this is practicable only over short distances.

Electric Railways. Turning to the electrical operation of railways in this country, this has hitherto been carried out on the "third-rail" system exclusively. In this system an additional rail is laid alongside the track, and by its means the electrical power is delivered to the train, returning either by the running rails or by a fourth rail laid for that purpose. The principal drawbacks to this system are humanitarian, as, even with the ordinary voltage (500 to 600 volts), an accidental contact with the third rail has frequently led to the death of the victim, and if a higher pressure were used, this untoward result would become almost inevitable. No Government would permit this risk, even if any railway company were prepared to run it ; and, therefore, if the third rail is used at all, it must be at low pressure, which entails the handling of heavy currents. It is impossible to convey these large currents to any considerable distance without excessive losses or exorbitant cost, and the only alternative until recently was to transmit the power at high pressure to sub-stations, where it was converted to low pressure for distribution to the railway. As the conversion necessitated the use of running machinery, attendance was necessary in each sub-station, at considerable expense. The converting machinery also was costly, and liable to breakdown.

Electrification of Steam Railroads. The development of the single-phase alternating-current motor, however, during the last few years, has entirely changed the position. It is now possible to transmit the power to the trains through a single overhead wire at very high pressure, sometimes even without any transformation whatever ; in this way the "live" conductor is removed altogether from the reach of human beings or animals, the cost of the electric equipment is reduced, costly sub-stations are done away with, line losses are enormously diminished, and various other advantages gained, with but few and unimportant drawbacks. Already several railways have been, and are being, equipped with this system on the Continent and in America, and one important company is about to adopt it for suburban service in London. Only by some such means is there any hope of eventually converting main lines of railway to electrical working.

High Speed Transit. The possibility of travelling at speeds much higher than those now in vogue has been much discussed of late years, and various projects have been put forward in which speeds of 100 miles per hour, or more, have been contemplated. On a Government railway between Berlin and Zossen, in Germany, specially strengthened for the purpose, experiments were carried out which culminated in the attainment of a speed of 130 miles an hour, thus proving the practicability of such a speed. Doubtless there would be no insuperable difficulty, from an engineering point of view, in constructing a high-speed railway between, say, London and Manchester ; but the question is whether such a line could be made to pay dividends, and as this is the only basis upon which railways can be constructed, except when they are owned by the State, it is at present difficult to raise capital for the purpose. As a matter of fact, an Act has been obtained for the construction of a high-speed railway between Liverpool and Manchester, but, though several years have elapsed since then, it has not yet been carried into effect.

The Future of Land Transit. So far as can at present be seen, the use of automobiles is likely to increase indefinitely,



6. A WESTINGHOUSE 135-TON SINGLE-PHASE ELECTRIC LOCOMOTIVE
Showing the overhead conductors and sliding collectors

while the horse will be gradually superseded, to a large extent; electric tramways will be extended further into the country, on the overhead trolley system; progress will be made with the electrification of steam railways, first urban, then suburban and inter-urban, and finally main lines. With the steady decrease in the cost of electrical energy, due to improvements in apparatus and to the increased demand, the cost of traction will tend to decrease, but not very much. There is not likely to be in the near future any material increase in the speed of transit, except in cities, where it is at present abnormally low.

The next important step is likely to be the transmission of high-tension electric currents through the air, enabling the large sources of power, such as the Scandinavian water power and the falls in Central Africa and in South and North America, to be fully utilised. The loss in transmission should be but small. The principal difficulty at present is the production of a satisfactory motor. Later on the power available from the ether, referred to in the article on Power, may be utilised.

Water Transit. Although swimming is the most natural and primitive mode of progression by water, it has never been more than an occasional means of transit over short distances, even when artificial aids like Boyton's dress are used, apart, of course, from its great value as a physical exercise. Very early, man invented the raft, and soon followed the canoe, the coracle, and other primitive forms of rowing boat. The transition from the raft to the dug-out canoe was, in itself, no mean stride, and the further step to the boat built of planks constituted a remarkable engineering achievement. The modern rowing boat is a conveyance of the greatest utility, comparable indeed with the bicycle except in speed, and greatly superior in point of durability; but its scope is limited to smooth waters, such as those of rivers and inland lakes, for ordinary boats cannot safely venture far on the sea. A smart oarsman can scull at the rate of about eight miles an hour, but only under racing conditions.

Sailing Boats. Sailing boats are generally larger than rowing boats, and are able to keep the sea in fair weather. An enormous amount of goods transport is carried on by means of sailing barges on rivers and canals, at a low rate of speed, but at very small cost per ton-mile. Where the canals are frequently crossed by low bridges, as in this country, recourse must be had to towing, generally by men or horses, at a rate of about two miles an hour. On the Continent considerable progress has been made with the electrical towing of canal-boats, by means of tractors running along the towing path, and fed with electricity by overhead trolley wires; in this way a much higher speed is attained, from four to six miles, the actual speed depending largely upon the width of the canal. In a narrow canal it is impossible to maintain a high rate of speed on account of the back current set up past the sides of the barge, which both retards the motion of the barge and damages the earthen banks. But little attempt seems to have been made to reduce this by better design.

Private sailing yachts are still used for long voyages, but have been largely superseded by steam yachts.

Sailing Ships. On a larger scale, the sailing boat becomes a ship, capable of voyaging to all parts of the world, and a large proportion of the world's trade is carried on to this day in vessels of this kind. The speed of sailing ships is much less than that of steamships, the former being dependent upon the strength and direction of the winds, and being unable, at the best, to sail much faster than a slow steamship. For many purposes, however, speed is of little moment compared with cost, and the latter is considerably less in the case of sailing ships, the capital outlay being less and, therefore, the charges much smaller. For the transport of grain, timber, etc., sailing ships are largely used ; the total number of such, in fact, is nearly equal to that of steamships in the world, though the net tonnage of the latter is about twice that of the former. As regards safety, it cannot be denied that steamships have a great advantage, the larger vessels being able to defy bad weather with impunity.

Steamships. For passenger transit the steamship stands pre-eminent, and the finest vessels ever built are destined almost solely for this purpose ; the huge liners which ply across the Atlantic resemble floating hotels, every possible provision being made for the comfort and entertainment of the passengers. Although the attainment of high speeds at sea necessitates the consumption of vast quantities of coal, the driving power varying approximately in proportion to the cube of the speed. Every effort has been put forward to reach higher and higher speeds, so that nowadays it is not uncommon for a speed of 20 or 22 knots to be maintained throughout a voyage of several thousand miles. A few steamships exist which have a gross tonnage exceeding 20,000 tons, and carry more than 2,000 passengers, in addition to the crew of 500 or 600 men. Such monsters, which are larger than the famous Great Eastern, are used only on the Atlantic service, smaller and slower vessels being employed on other routes.

The Marine Turbine. Until quite recently the reciprocating type of engine was invariably used for the propulsion of steamships ; the development of the steam turbine, however, has inaugurated a revolution in this respect. The turbine is eminently adapted to the purpose, its motion being wholly rotational, like that of the propeller which it drives. The conversion of the reciprocating motion of the ordinary type of engine into rotary motion involves the introduction of vibrations which it is impossible to neutralise completely, and the resulting pulsations are felt throughout the ship, whereas in a ship equipped with turbine-driven propellers of good design it is difficult to realise that the engines are in motion at all. This fact is of great importance in the transport of passengers. Another feature of the turbine is its remarkable economy. Higher speeds can be obtained with a smaller expenditure of fuel, and the turbine requires less attendance than the reciprocating engine. Hence it comes about that the largest and fastest steamships ever built—the 30,000-ton leviathans of the Cunard line—are equipped with Parsons' steam turbines of 65,000-horse power, a fact which implies immense confidence in the capabilities of the turbine, seeing that it has only recently been employed for the propulsion of very large vessels. Obviously, the turbine is ideally adapted for such a service as that between Great Britain and the Continent, and has already been adopted for several of the Channel steamers.

The Power of the Future. It is sometimes suggested that, in the future, vessels will be electrically driven. This, however, is a prophecy which is by no means likely to be realised at an early date. At present the only successful type of electrically-propelled boat is the electric launch, which carries a battery of accumulators. These must be charged at frequent intervals, and, therefore, the launch can never travel far from a charging station, though, of course, such station may be on board ship. Hitherto electric launches have been used only on rivers and other inland waters.

The prospect of propelling vessels by means of gas-engines is much brighter, and already a number of launches have been fitted with suction gas-producers and gas-engines of several hundred horse-power. The system, so far as it relates to marine propulsion, is still in the early stages of development, but at no very distant period we shall probably see large vessels equipped with gas producers and gas-engines and making long voyages. Launches fitted with petrol-engines are becoming by no means rare, and there is an undoubted field for this type of conveyance. On the Volga a 1,000-ton barge has been equipped with Diesel oil-engines, driving dynamos which supply electric power to motors coupled to screw propellers. This combination is said to be very successful. There are many advantages in having the propeller driven by an electric motor coupled direct.

Costs of Water Transit. The cost of conveyance by water depends upon so many and various conditions that it is exceedingly difficult to arrive at reliable general estimates.

We have, however, made some investigations into the cost of travelling by steamboat for long and short distances, with the following results. Sea journeys may conveniently be divided into two classes—short journeys, such as those between this country and Ireland, or the western countries of the Continent ; and long journeys, such as crossing the Atlantic, or travelling to India and Australia.

In the case of the former, allowing for first-class accommodation, the cost varies between 0·4d.

and 1·17d. per statute mile, averaging about ¾d. per mile per passenger, at speeds also varying over wide limits, 12 to 26 miles an hour. The longest journeys are the cheapest.

In the case of long ocean voyages, allowing for good accommodation, but not the best (for which fabulous prices may be paid), the cost varies from about 0·58d. to 0·92d., averaging again ¾d. per mile. This is exclusive of food and attendance in each case. The speed depends upon the route and the line of steamships, and varies from 15 to 27 miles per hour. Here, again, the longest journeys are the cheapest.

As regards the cost of transport of goods by sea, a complicated system of classification is employed, and the rates vary widely on different routes. Hence, it is impossible in the space at command to convey any useful idea of the cost of freight by water.

Air Transit. Hitherto we have considered only means of transit over the surface of land and sea. There remains to be discussed the possibility of transit through the substance of air and water without contact with other media—transit through the earth in this sense being obviously impossible. This class of means of locomotion differs very markedly from those previously dealt with. When travelling on the land surface, motion is derived from the reaction between the solid earth and the vehicle due to the exercise of force between these bodies, or from the force of the wind acting on sails (the latter mode being employed only in rare cases). When travelling on the sea, motion is again derived from reaction between the sea-water and the vessel, the sea acting partly after the fashion of a solid body by virtue of its inertia, or from the force of the wind, or from the motion of the water itself. In the remaining case the vehicle is wholly immersed in the medium which both supports it and provides the necessary reaction without which locomotion is impossible, and the problems to be solved are correspondingly changed

Factors in the Air Transit Problem. In the case of transit through the air, four factors have to be considered: flotation, propulsion, direction, and balance. The first of these is almost invariably obtained by means of a balloon filled with a gas of less density than that of the atmosphere, such as hydrogen or coal-gas. Hot air has been employed for this purpose, but is never used nowadays. Flotation alone is easily secured, and equilibration is readily attained by simply suspending the whole of the weight to be carried in a car of small dimensions beneath a balloon of spherical shape. With this arrangement ascents can be made to a height of several miles with a considerable degree of safety; but the balloon, with its load, is entirely at the mercy of the air currents, and the aeronaut can do no more than select, to some extent, a particular current by varying the buoyancy of the balloon, and thus rising or falling. In practice it may be taken that the direction and speed of travel are beyond the control of the aeronaut. In spite of these limitations, remarkable voyages have been accomplished in balloons.

Accomplishments in Air Transit. The fastest journey recorded up to the year 1784 was performed in a balloon, a distance of 150 miles being covered at a speed occasionally exceeding 24 miles per hour. The English Channel was crossed in the following year, and a speed of nearly 80 miles an hour was attained in the same year, over a distance of 46 miles. In 1802, 60 miles was covered in 45 minutes, or at the rate of 80 miles an hour, and in 1804, a distance of 800 miles was traversed in 20 hours. Numerous other examples could be given; but the only important instance of the use of balloons as a means of transit is found in the siege of Paris, during which 64 balloons were sent out of the city; of these 57 succeeded in escaping and delivering their despatches. These balloons carried out 155 persons, nine tons of despatches, and 3,000,000 letters. Nevertheless, it was found impossible to enter the city from without by means of balloons.

Dirigible Balloons. For hundreds of years men have tried to find some means of travelling in the air, but it is only during recent years that the advance of knowledge, more especially in the manufacture of light motors, has rendered a solution practical. There are three main lines of experiments: (1) Balloons; (2) aeroplanes; and (3) what may be called "flapping machines."

The variations in balloons driven by power have been but slight, consisting chiefly in varying the motive power, the arrangement of the fans, and the shape of the balloon. The first practical flying machine was built by Henri Giffard in 1852. It was 140 ft. long and 40 ft. in diameter, driven by an engine and boiler developing about 3-horse power, and weighing 330 lb.

There have been many other attempts since to solve the problem with dirigible balloons, the most successful being that of Tissandier Brothers in 1881, and that of Majors Renard and Krebbs in 1884. The latter used a primary electric battery giving about 5-horse power, and weighing with the motor 1,140 lb.

Experiments with Dirigible Balloons. Far more work in this direction has been done abroad than in England. The only attempts that are worth mentioning in England have been one by Mr. A. Gaudron, in 1898, with a balloon 60 ft. long and a 3½-horse power petrol motor; one in 1901, when Mr. Stanley Spencer passed over London, and one in August, 1905, when Dr. Barton and Mr. F. L. Rawson went from the Alexandra Palace to Woodford. Dr. Barton had been experimenting for many years, and the special feature in his airship was the use of aeroplanes between the balloon and the motive power. This is almost the only real novelty that there has been for many years. Two motors were used, giving nominally 50-horse power each, the total weight of the two motors being just over 500 lb. complete with carburetter, fly-wheel, etc., showing the great advance that there has been of late years in the design of light motors. Since this ascent still further advances have been made, and the weight has been reduced from 10 to about 6 lb. per brake horse-power.

The two most successful experimenters of late years have been M. Santos-Dumont, and M. Lebaudy. The former succeeded, in 1901, in circumnavigating the Eiffel Tower in Paris and winning the prize offered by M. Deutsch to the first to perform that feat. The experiments of M. Lebaudy have culminated in his airship being taken over by the French Government. It is a great pity that the English Government are not moving more in this direction.

Aeroplanes. With regard to the second system, that of aeroplanes, which, when driven by propellers, rise in air by the virtue of the pressure of the air on the under side of large plane surfaces something after the manner of a kite, up to the present there has been but little success. The two most successful experimenters with aeroplanes in the form of gliding machines have been Herr Lillientaal and Mr. Pilcher. Both lost their lives while experimenting, though in neither case were they using motive power. In the first the aeroplane was allowed to glide through the air, Herr Lillientaal starting at the top of a hill, and in the second case the machine was being pulled along by a horse. There is not much doubt, however, that the first real successful flying machine will make use of some form of aeroplane. Considerable success has been recently obtained by the Brothers Wright in America by this form of machine, and experiments have been made recently with a full-sized machine in England by Dr. Barton and Mr. F. L. Rawson, and also in France. There is no difficulty at the present time in rising from the ground and maintaining a considerable speed even against a moderate wind, the difficulties being in balancing and in coming safely to the ground at the end of the flight.

Flapping Machines. With regard to the third method, that of flapping machines, no success worth speaking of has been obtained, although Herr Kress has completed models which rise from the ground, and Dr. Hutchesson, of Cambridge, has also succeeded in rising.

Very good results have been obtained in some trials, which have been kept secret, where a speed of about 10 miles an hour and a lift of 200 lb. per horse-power were obtained, without the use of any balloon or aeroplane. The principal advantage, however, of this flying machine was that it could rise or fall in the air practically without forward movement, and augment or reduce the speed when once in the air, this making it very easy to start or come to the ground again.

There is not much doubt that we are on the eve of a great advance in airships, as all the main difficulties have now been solved, and it is only a question of working out the minor details.

Submarine Navigation. Turning now to submarine navigation, this is in essence a very similar problem to that of aeronautics, the vessel being wholly immersed in the medium which both sustains it and provides the reaction upon which its forward progress depends. The difficulties, however, are in this case much less than in aerial navigation, owing to the greater density of the water, which provides abundance of support for the vessel. The essential difference in this respect is that the submarine boat has to be forcibly immersed, while the passengers must be absolutely shielded from the supporting medium. The first practical submarine was built in 1776, but little progress was made until Nordenfelt took up the matter in 1885. His boats, however, were a failure when submerged, owing to their instability, though they travelled well enough at the surface. France followed with the Gymnote, in 1888, and achieved considerable success. The Gymnote was propelled by electricity at the rate of six knots when submerged, and displaced 30 tons. The Gustave Zédé was built in 1893, displacing 226 tons. This vessel was driven with electric motors of 720-horse power at a speed of 9 knots when submerged. Later designs were of the "submersible" type, which was propelled by steam on the surface, and by electricity when submerged, with a range of 25 miles at 8 knots, 72 miles at 5 knots. The displacement was 200 tons when submerged. British submarines are built on the American Holland model; the first, in 1901, displaced 120 tons when submerged, and was propelled by 160-horse power gasoline motors on the surface at 8 knots, by 70-horse power electric motors when submerged at 7 knots, for four hours at a time. The batteries could be recharged by means of the gasoline motor Like most modern submarines, these were submerged by inclining the horizontal rudders while going ahead. The latest boat, of which particulars are not yet published, is considerably smaller than those hitherto built. It is entirely electrically driven and, so far, has been very successful.

The Future of the Submarine. In spite of the great progress that has been made during the last few years, the submarine boat remains a dangerous vessel in which to travel, and can be used only for purposes of warfare, in which pursuit risks must be faced. There is no prospect that in the near future submarine navigation will become a practical means of transit for general use. Although the effects of wind and waves are neutralised at a depth of a few fathoms, other dangers and difficulties of even greater magnitude are encountered, not the least of which is that of steering a true course in the impenetrable darkness which reigns beneath the surface, and the necessity of maintaining a respirable atmosphere in the vessel.

ALGEBRAIC DIVISION

By HERBERT J. ALLPORT, M.A

DIVISION OF A COMPOUND EXPRESSION BY A MONOMIAL

40. From the result of Art. **26** it follows, since division is the inverse of multiplication, that *to divide a compound expression by a monomial we take the sum of the quotients formed by dividing the separate terms of the compound expression by the monomial.*

Example 1. Divide $6x^4 - 2x^3 + 4x^2$ by $-2x$.

Here, we divide (i.) $6x^4$ by $-2x$, (ii.) $-2x^3$ by $-2x$, and (iii.) $+4x^2$ by $-2x$.

Hence, the required result is

$$-3x^3 + x^2 - 2x \quad \underline{\textit{Ans.}}$$

Example 2. Divide $15x^4y^5 - 12x^3y^6 + 3x^2y^3$ by $3x^2y$.

The quotient $= 5x^2y^4 - 4xy^5 + y^2 \quad \underline{\textit{Ans.}}$

DIVISION BY A COMPOUND EXPRESSION

41. The method will be best understood by considering an example. Suppose we have to divide

$$10x - 5x^2 - 8 + x^3 \text{ by } x - 2.$$

We must first arrange both dividend and divisor either according to descending or according to ascending powers of some letter contained in each. In our present example the only letter is x.

On thus rearranging the terms we obtain $x^3 - 5x^2 + 10x - 8$ to be divided by $x - 2$.

$$
\begin{array}{rl}
x-2)\,x^3-5x^2+10x-8\,(& \underline{x^2-3x+4 \quad \textit{Ans.}}\\
\underline{x^3-2x^2} & \\
-3x^2+10x-8 & \\
\underline{-3x^2+6x} & \\
4x-8 & \\
4x-8 &
\end{array}
$$

Now, it is clear that the term of the highest degree, x^3, of the dividend must be the product of the terms of the highest degree in the quotient and the divisor. Therefore, the term of highest degree of the quotient is found by dividing x^3 of the dividend by x of the divisor; that is, the first term of the quotient is x^2. Now multiply the *whole* divisor, $x - 2$, by this x^2, and subtract the product from the dividend. This gives us $-3x^2 + 10x - 8$ for the remainder.

Evidently this remainder must be equal to the product of the divisor and the terms of the quotient, which have still to be found. Hence, in the same way as before, we see that the second term of the quotient is found by dividing $-3x^2$ of this remainder by x of the divisor; that is, the second term of the quotient is $-3x$. Multiply the whole divisor, $x - 2$, by this $-3x$, and subtract the product from $-3x^2 + 10x - 8$. This gives $4x - 8$ for our second remainder. Then, exactly as before, we see that the third term of the quotient is obtained by dividing $4x$ of the second remainder by x of the divisor; that is, the third term of the quotient is 4. Multiply the whole divisor, $x - 2$, by 4, and subtract from $4x - 8$. There is now no remainder.

We have thus subtracted x^2 times the divisor, $-3x$ times the divisor, and 4 times the divisor; that is, in all, we have subtracted $x^2 - 3x + 4$ times the divisor and found that there is no remainder. It follows, therefore, that the dividend is equal to $x^2 - 3x + 4$ times the divisor. Thus $x^2 - 3x + 4$ is the required quotient.

42. We see, then, that the process is as follows:

1. Arrange the divisor and the dividend in ascending or in descending powers of some common letter.
2. Divide the first term of the dividend by the first term of the divisor, to obtain the first term of the quotient.
3. Multiply the *whole* divisor by the first term of the quotient and subtract the product from the dividend.
4. Treat the remainder as a new dividend, and repeat the process until the highest term of the remainder is of a lower degree than the highest term of the divisor.

We shall now work a few other examples.

Example 1. Divide $4x^4 - 8x^3 - 19x^2 + 53x - 30$ by $x^2 - 3x + 2$.

$$
\begin{array}{rl}
x^2-3x+2)\,4x^4-8x^3-19x^2+53x-30\,(& \underline{4x^2+4x}\\
\underline{4x^4-12x^3+8x^2} & \underline{-15 \quad \textit{Ans.}}\\
4x^3-27x^2+53x & \\
\underline{4x^3-12x^2+8x} & \\
-15x^2+45x-30 & \\
\underline{-15x^2+45x-30} &
\end{array}
$$

Notice that it is not necessary to "bring down" *every* term of the dividend after each subtraction. In the above example, for instance, the -30 is not required till we reach the second remainder.

Some examples require greater care in arranging the terms for each subtraction.

Example 2. Divide $a^3 + b^3 + c^3 - 3abc$ by $a + b + c$.

Arrange the dividend in powers of a. Treat b as next in importance to a.

$$\begin{array}{l}
a+b+c)a^3-3abc+b^3+c^3(\underline{a^2-ab-ac+b^2-bc+c^2} \quad \text{Ans.}\\
\qquad a^3+a^2b+a^2c\\
\qquad\quad -a^2b-a^2c-3abc\\
\qquad\quad -a^2b-ab^2-abc\\
\qquad\qquad -a^2c+ab^2-2abc\\
\qquad\qquad -a^2c-abc-ac^2\\
\qquad\qquad\qquad ab^2-abc+ac^2+b^3\\
\qquad\qquad\qquad ab^2+b^3+b^2c\\
\qquad\qquad\qquad\quad -abc+ac^2-b^2c\\
\qquad\qquad\qquad\quad -abc-b^2c-bc^2\\
\qquad\qquad\qquad\qquad ac^2+bc^2+c^3\\
\qquad\qquad\qquad\qquad ac^2+bc^2+c^3
\end{array}$$

The above division shows us that $a^3+b^3+c^3-3abc=(a+b+c)(a^2+b^2+c^2-bc-ca-ab)$.

This result is very important, and should be remembered.

Example 8. Divide $a^5+a^4b+a^3b^2-a^3+a^2+b^3$ by a^3-a+b.

$$\begin{array}{l}
a^3-a+b)a^5+a^4b+a^3b^2-a^3+a^2+b^3(a^2+ab+b^2\\
\qquad a^5-a^3+a^2b\\
\qquad\quad a^4b+a^3b^2+a^2-a^2b+b^3\\
\qquad\quad a^4b-a^2b+ab^2\\
\qquad\qquad a^3b^2+a^2-ab^2+b^3\\
\qquad\qquad a^3b^2-ab^2+b^3\\
\qquad\qquad\quad a^2.
\end{array}$$

Here the quotient is a^2+ab+b^2, and there is a remainder a^2.

EXAMPLES 6

Divide

1. $-35a^2b^2c$ by $5ab$.
2. $12xy^4z^3$ by $-2y^2z^2$.
3. $-105abc$ by $-5abc$.
4. $4x^7y^2z^8$ by $4x^5yz$.
5. $27x^6-36x^3+18x^2$ by $-9x$.
6. $4x^2yz+6xy^2z-8xyz^2$ by $2xyz$.
7. $\frac{3}{4}a^2-\frac{1}{2}ab+3ac$ by $-\frac{1}{4}a$.
8. x^2-3x-4 by $x-4$.
9. $6x^2-19x+10$ by $2x-5$.
10. $2a^2-a-4a^5+1-3a^3-a^4$ by $a+1+a^2$.
11. $1-x^6$ by $1-x^2$.
12. x^4-a^4 by $x+a$.
13. $a^3-b^3-c^3-3abc$ by $a-b-c$.
14. $x^2-y^2+xz-yz$ by $x+y+z$.
15. $(a-1)^3+b^3$ by $a+b-1$.

7. $x^4-x^3-2x^2+5x-3$.
8. $x^5-a^2x^3+(2ab-c)x^2+(ac-b^2)x-bc$.
9. $x^6-x^5y-4x^4y^2+3x^3y^3+x^2y^4+2xy^5+2y^6$.
10. $a^3+b^3+c^3-3abc$.
11. $(1-x)(1+x)(1+x^2)$
 $=(1-x^2)(1+x^2)$
 $=1-x^4$.
12. $(x^2+y^2+xy)(x^2+y^2-xy)(x^4-x^2y^2+y^4)$
 $=\{(x^2+y^2)^2-x^2y^2\}(x^4+y^4-x^2y^2)$
 $=(x^4+y^4+x^2y^2)(x^4+y^4-x^2y^2)$
 $=(x^4+y^4)^2-x^4y^4$
 $=x^8+x^4y^4+y^8$.
13. $\{(\overline{b+c}+a)(\overline{b+c}-a)\}\{(a-\overline{b-c})(a+\overline{b-c})\}$
 $=\{(b+c)^2-a^2\}\{a^2-(b-c)^2\}$. Art. **34**.
 $=(b^2+c^2+2bc-a^2)(a^2-b^2-c^2+2bc)$ Art. **32**.
 $=(2bc+\overline{b^2+c^2-a^2})(2bc-\overline{b^2+c^2-a^2})$ Art. **19**.
 $=4b^2c^2-(b^2+c^2-a^2)^2$. Art. **34**.
 $=2b^2c^2+2c^2a^2+2a^2b^2-a^4-b^4-c^4$. Art. **3**
14. $(x-y)^2+(y-z)^2+(z-x)^2$
 $=x^2+y^2-2xy+y^2+z^2-2yz+z^2+x^2-2zx$
 $=2(x^2+y^2+z^2-yz-zx-xy)$.
15. $(x+2)(x+3)(x+4)(x+5)$

 Since $2+5=3+4$, we multiply together the first and fourth factors and then the second and third, thus obtaining
 $(x^2+7x+10)(x^2+7x+12)$
 $=(x^2+7x)^2+22(x^2+7x)+120$
 $=x^4+14x^3+49x^2+22x^2+154x+120$
 $=x^4+14x^3+71x^2+154x+120$.
16. $x^2y^2p^2-x^2y^2q^2+p^2q^2x^2-p^2q^2y^2+p^2q^2y$ $-p^2x^2y^2+q^2x^2y^2-p^2q^2x^2=0$.
17. $9x^2-81+2x^2-8x+8-4x^2-4x+8$ $-6x^2+12x-6=x^2+1$.
18. $x^2+9y^2+16z^2-24yz+8zx-6xy$.
19. $9a^4-12a^3+34a^2-20a+25$.
20. $a^2+b^2+c^2+d^2+2ab-2ac-2ad-2b$ $-2bd+2cd$.
21. $(a+b)^2(a-b)^2=(a^2-b^2)^2=a^4-2a^2$ $+b^4$.
22. $27x^3-27x^2y+9xy^2-y^3$.
23. $1-12a+48a^2-64a^3$.
24. $(x+\overline{y+z})^3=x^3+3x^2(y+z)+3x(y+z)^2+(y+z)^3=x^3+3x^2y+3x^2z+3xy^2+6xyz+3xz^2+y^3+z^3+3y^2z+3yz^2$
25. $(x-y-z)^3$ is obtained by changing the signs of y and z in the last example.

Thus,
$x^3-3x^2y-3x^2z+3xy^2+6xyz+3xz^2-y^3-z^3-3y^2z-3yz^2$.

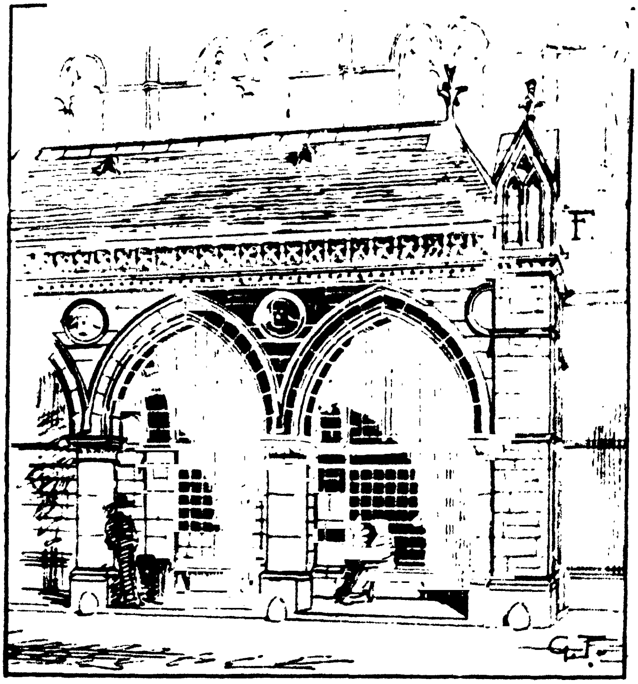
ARCHITECTURE
continued from
page 2130

By GASPARD TOURNIER

THE novice is constantly finding he is hampered in his conception for an elevation through imperative features on the plans which frustrate it, and he is tempted to sacrifice these for the sake of what he thinks will produce a finer effect. This he should never do, for no elevation which maims a good plan is ever a success. He should let the plan tell its own story boldly in the elevations. That way alone leads to legitimate originality. Fig. 22 is a fine design for a Technical School at Trowbridge, by Messrs. Wimperis & East. Ordinary orthodoxy called for the side wings to go up to the main cornice with some form of terminal emphasis, but there was no need for it in the plan, so the architects frankly omitted it, and the result is striking and happy. Among our foremost artistic architects who are loyal to plan and let their architecture grow from it is J. J. Stevenson. Fig. 25 shows an example of a house designed by him at Prince's Gate. He has been accused of being an extremist in rationalism—instanced in the exposure of naked gas pipes on the face of interior walls—but *all* his work is full of good essence which the student will do well to analyse carefully.

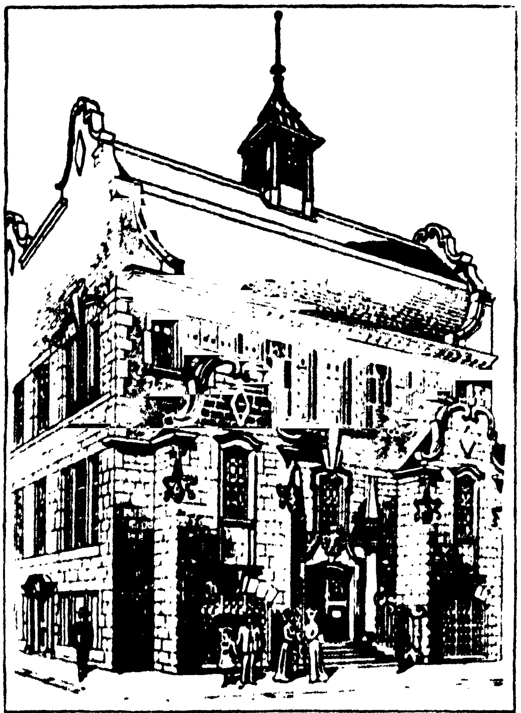
20. IMPERFECT BALANCE



21. A GOTHIC ARCADE

Vertical and Horizontal Lines. The relation of vertical to horizontal lines is an important matter to which beginners always fail to give enough attention. When a design needs to have its height emphasised, vertical lines should predominate over horizontal ones, and the reverse should occur when a low, broad result is wanted. But in the first instance, the horizontal lines should not be too often broken in their continuity.

The London Law Courts [23] is an example of this. *Breaks*, such as A, B, and C, are overdone, and tend to disjoint the building into too many unasso-



22. DESIGN FOR A TECHNICAL SCHOOL
Messrs. Wimperis & East, Architects. A fine example of a good plan telling its own story

ciated divisions. The entire stopping of the horizontal continuation of one storey, as at DD, is often permissible to give height to what adjoins ; and so are breaks such as F [21]. It does not follow that even important horizontal members, such as deep cornices, should not be broken through when environment asks it, as in 24, but moderation is called for in all these cases.

Harmonious Surroundings. A building should be in harmony with its surroundings. Often a good design fails to look well when erected by reason of its lines jarring with those of its environment. For instance, a village church in a valley, or on a plain with a background of hills, should not have an orthodox spire darting up. Fig. 26 is a good example of a church designed in harmony with the hills around it ; and the slightly sloping or batteyed walls also help sympathetically towards the object attained.

Symmetry Versus Balance. Symmetry is a correspondence of parts on each side of a centre. Without due attention to this, a balance of parts is necessary, or the result will be lumpy and unhomogeneous. Fig. 20 is an example of bad balance. Fig. 27 shows the same theme better balanced. It is exceedingly difficult to define in words the matter here involved. Balance does not involve a set arrangement of parts, as of chessmen on a board, but a pleasing relationship between them. This happens when a kind of drift and counter drift of the lines have been played against each other, and in this way the members of the design compensate each other for their irregular shapes. A drift of line, curved or straight [28], running in one direction, suggests a want, at the end, of being met by a counter drift of lines across the path, leading in this way to the formation of

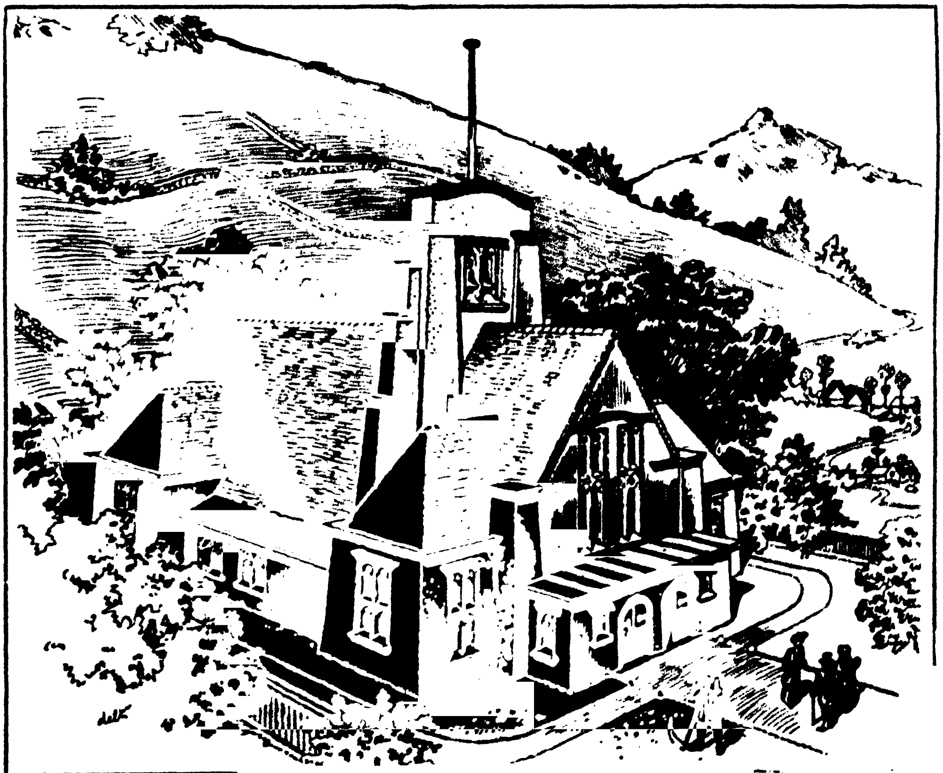
25. HOUSE AT PRINCE'S GATE

An instance fulfilling the principle that plan should influence elevation

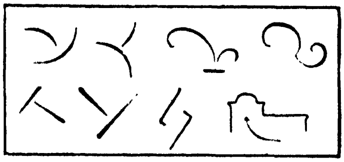


[illegible]. A VILLAGE CHURCH

E. B. Lamb, Architect. Well illustrating the principle that the lines of a building should always sympathise with the background of the site masses in rhythmic balance. Many definitions have been given. We suggest this simile, by which we have often found a student derive an enlightening hint when other explanations have been misunderstood by him; but it is by personal practice in designing that he can best get at the right grasp of this matter.

27. BALANCE

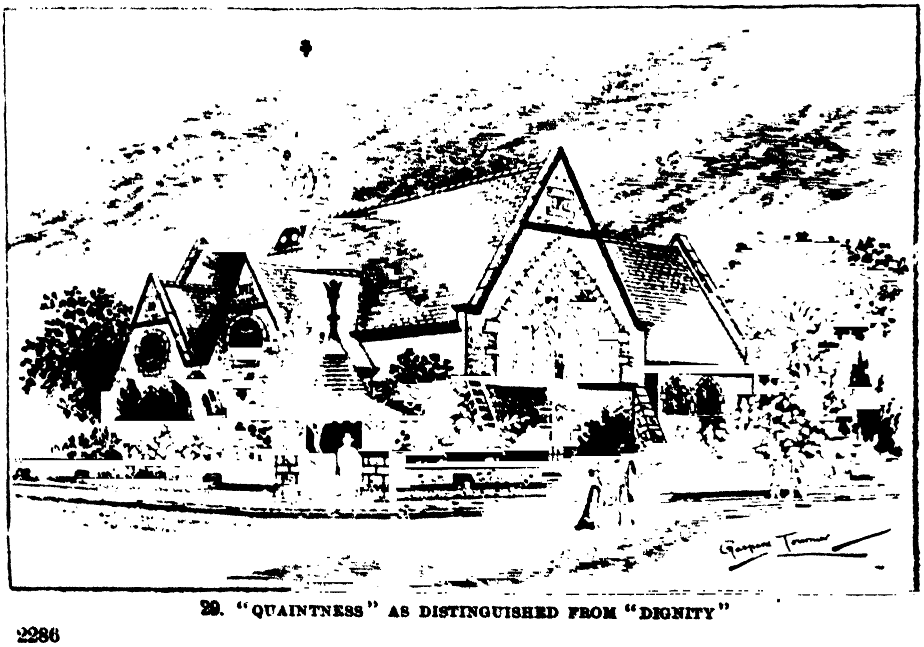
Beginners are apt to confuse quaintness and dignity in one design, but they should not be confounded. Fig. 29 is quaint, 8 [page 2120] is dignified. The one is simply a small church of inexpensive construction, the other a large building of noble proportions; but these attributes are not those involved. Quaintness in large buildings can be given impressive importance, as in many cases of Flemish town halls, etc., and dignity can be also present, perhaps, by the addition of a bank front of very narrow width. The two attributes to which we refer are incongruous, and should not be jumbled together.



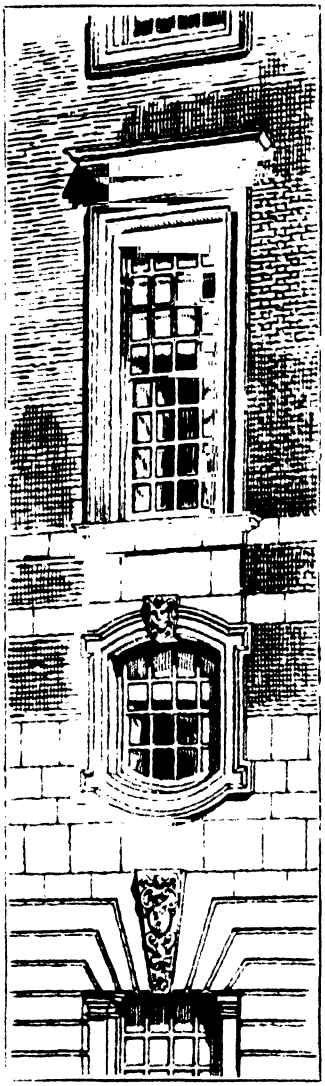
28. THE PRINCIPLE OF BALANCE AS DISTINGUISHED FROM SYMMETRY

The Supporting of Mass. The weight and visual bulk of an object must have below it that which satisfies the eye as being just adequate for its support, neither more nor less. This principle in large buildings is often violated. Study it first in minor items, such as in a pedestal, and that which is on it. Statues frequently fail in this, the base outraging the eye through its excess.

In Fig. 33, the right ratio is very nearly satisfied. Pedestals supporting standards for gas or electric light repeatedly show this want—standards starting with excessively massive bulk, attenuating to such an ethereally weightless thing as a flame or incandescent glow-spot. There should be more gradation of members from the pedestal to the light. The medium



29. "QUAINTNESS" AS DISTINGUISHED FROM "DIGNITY"



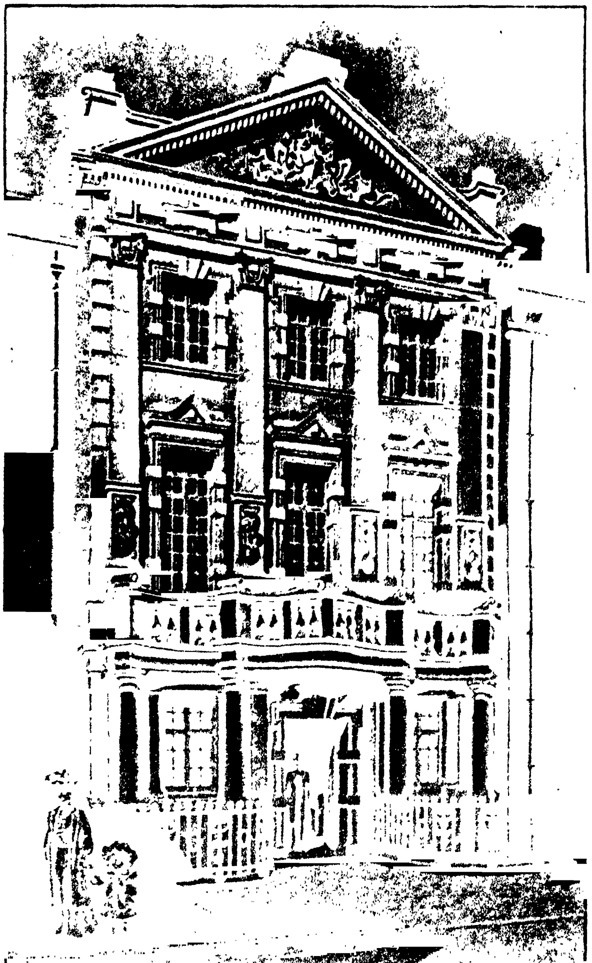
30. WINDOWS OF "COUNTRY LIFE" OFFICES, COVENT GARDEN

E. L. Lutyen, Architect. A fine example of justified "playfulness" in curved lines

need not necessarily be a figure, but metal or other branchings upward, conceived in a similar spirit. This principle is akin to, but not the same as, the feeling which has led the shafts of columns, in classic architecture, to be tapered upwards [see the Five Orders of Architecture], or the sloping of the design for the grave in **34**. This is called *entasis*. Some hold that the satisfaction it gives to the eye is due to an optical tendency for all vertical lines to appear to fall outwards. But, if this is so, the eye would long since have called for all vertical lines to all buildings to conform to the rule, and this has not happened. The feeling seems more to be the outcome of special cases where the subject designed requires its stability to be unusually emphasised.

Playfulness in Curves. A poet has said: "Curved is the line of beauty." There is a tendency in modern Classic Renaissance to take this very much to heart—more so than many critics approve of. But, when kept within bounds, as a contrast to straight lines, playfulness in curves charms exceedingly. The sill to the window in **30**, taken from Mr. E. L. Lutyen's masterly design for "Country Life" offices in Covent Garden, is very happy. The impulse has also led to an increase of curved lines by giving them to members horizontal in plane [**31**].

To avoid intemperance in curves, the student should analyse "Spanish Renaissance and the Flamboyant Period," where it is carried to excess. The beginner easily perceives the crime of such atrocities as a wallpaper designed to imitate grained oak, or a cement surface scratched with lines to represent



31. A BANK ELEVATION

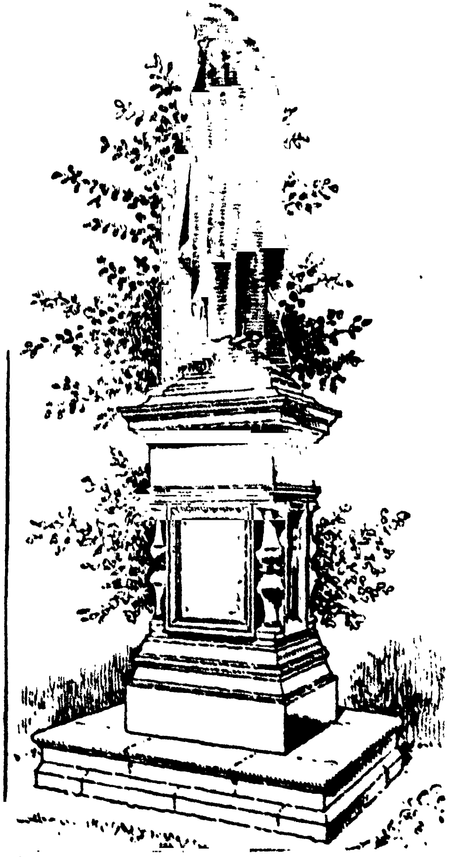
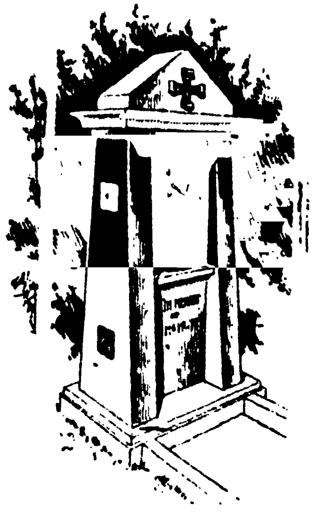
32. GOTHIC MOULDINGS
A style distinct from classic

the joints of stones; but, apart from actual shams, no materials should be called on to be manipulated in a way which, though physically quite possible, is not appropriate in their position. For good style, no feature should be forced into inappropriate positions or shapes.

The Functions of Mouldings. Students are apt to start with wrong ideas of the purpose of a moulding. They too exclusively consider how it looks when drawn on paper in cross section at a right angle to the moulding. On the ultimate building this section is never seen except on occasions when the moulding abuts direct against a flat surface at the end, and at right angles to the moulding. Regard must be given to how the moulding will look at the mitre when it turns at an angle. Then the section seen along the edge of the mitre has the same perpendicular proportions, but the horizontal proportions have widened out. The primary purpose of a moulding is to obtain shaded lines on the building of varied width and degrees of depth—some hard, some strong, got by angles more or less undercut in section, and some soft or blended, got by curves in section. Then, as regards the style or feeling put into the line of the section's profile, each historic style of architecture has its own type; but, for the practical purposes of modern designing, these group into two types—the Classic and the Gothic. Typical classic mouldings are seen in the Five Orders of Architecture, Gothic ones in 32. These two methods of getting shaded lines mix in the Elizabethan style of architecture, which was the basis of our English Renaissance. The fore-named purpose of mouldings is the first consideration; the right idea of their form comes with the growth of the student's artistic sense of fitness in all things.



33. CAXTON MONUMENT, EMBANKMENT GARDENS, LONDON. E. W. Goodwin, Architect



34. DESIGN FOR A GRAVE

Ornamentations. Ornamentation should afford a contrast to plain parts, and be something more than mere ornament.

Space for light to windows and egress to doors must not be sacrificed for artistic effects obtained unreasonably at the expense of these requisites, as is often the case.

The physiognomy of a building should tell its purpose. A church should look like a church, not like a theatre. The use for which a building is to be erected should be the keynote of the architectural melody it plays.

These are the main points where we have found students going wrong in architectural designing, through disregard or misconceptions of their meaning. In no case should the designer be satisfied with his work until it can stand the ordeal of being submitted to the fore-named considerations and satisfying them without any apparent effort or strain. He must not think any of them trifles which may be violated for the sake of what he may consider a brilliantly good point.

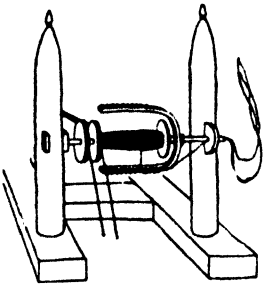
Architecture concluded

FIRST PROCESSES IN SPINNING

Slubbing and Roving. The Bobbin and Flyer. Slubbing, Intermediate, and Roving Frames. Wool Spinning. Gilling Machines

By W. S. MURPHY

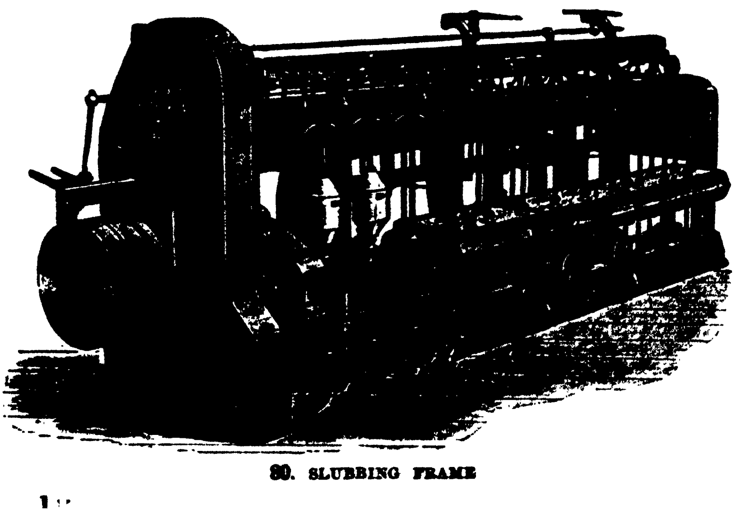
Bobbin and Flyer. Every textile worker should be acquainted with the principle of the bobbin and flyer [**79**]. At one point and another, in all branches of our industry, it comes into play. The original of this fine contrivance was part of the Saxony wheel, a picture of which has been given. Upon the head of the spinning-wheel, supported by two wooden pins, sits a horizontal spindle, holding a bobbin. On the head of the spindle a fork is fixed, the legs projecting parallel with bobbin and spindle. This fork is the flyer, hollow at the head, and the legs set with little hooks. From the big fly-wheel below, two bands come up, one passing round the wharf of the spindle, and one passing round the smaller wharf that controls the bobbin. It needs but a little knowledge of mechanics to enable one to understand that if two driving bands of the same speed are put round wharves of different sizes, the speed of the smaller must be greater than the speed of the larger. Conversely, the larger can travel an equal distance at a slower rate of speed. The spinner's thread is passed through the head of the flyer, in through one of the hooks on its leg, and round the bobbin. When the wheel is set agoing, the bobbin, by its greater speed, drags at the thread, while the flyer, whirling round, holds and draws out the thread, giving it a twist.



79. BOBBIN AND FLYER

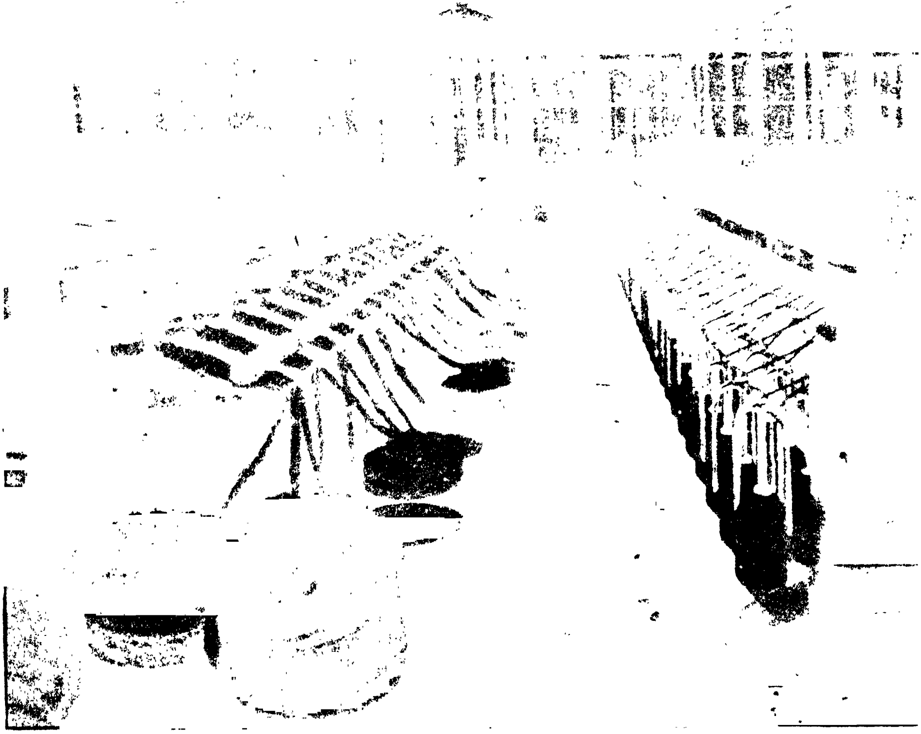
The rude contrivance of some unknown spinner has been largely developed in the hands of the great mechanics who have made the textile factory what it is; but the principle remains, and we shall see it on every variety of spinning frame.

Cotton. Cotton manufacture, as we have observed, is very definite. One operation follows another in rapid sequence. The slivers are taken from the drawing frames, and the cans are set behind the slubbers [**81**]. As a rule, the slivers are doubled here once again, two slivers being fed to each set of rollers on the slubbing frame. When the doubled sliver has passed through the drawing rollers, it passes through the tube of a flyer set on a spindle, is hooked in the hook of the flyer leg, and thence round a bobbin revolving underneath. The bobbin would seem to be actuated by the spindle, but it is not. A separate drive controls the movements of the bobbin. If bobbin and flyer were revolving at the same speed, no yarn could be wound. The drawing rollers are constantly giving off yarn. Therefore the difference in the speeds of the bobbin and the flyer must be regulated according to the length of the yarn given off by the rollers. You may arrange to make the flyer lead, or give the lead to the bobbin, but the difference in speed must be had and maintained. The yarn is taken on the bobbin [**82**], but if it and the flyer remain in unchanged positions, the yarn will be wound all on one part of the bobbin. For this, provision has been made in the lifter plate, shown in **80**, which carries the bobbin up and down with regular automatic movement.



80. SLUBBING FRAME

Another difficulty occurs. The bobbin at the start is a thin tube; but as the thick rope winds upon it its circumference grows. If the same speed of drive is kept on, the surface travel of the bobbin must increase, and the ratio between it and the flyer alter. Many contrivances have been devised to quicken or slacken the speed of the



81. DRAWING AND SLUBBING FRAMES (Horrockses, Crewdson, & Co., Ltd., Preston)

bobbin on a regular ratio; but there are now two in common use.

Bobbin Drive. The cone drive is made up of pairs of cones, driving and driven cone opposing each other in reverse. A belt connects the two, and the bobbin takes its speed from the driven cone. As the belt travels in regular gradation from the one side to the other, the speed of the bobbins is graded to the thickness of the yarn wound. The other device is on a different principle, and has the merit of giving unity to the movements of the whole frame. We saw the lifter plate move up and down; in this differential mechanism the lifter plate, at both the top and bottom ends of its traverse, releases a catch, which lets the regulating cone or bowl change its position. This bowl is fixed on the end of the rod which drives the bobbins; it is actuated by two discs running in opposite directions; the nearer the centre of the discs, the smaller its area of revolution, and therefore the slower; the further out the bowl is between the discs, the more rapid its revolution, and therefore the stronger and swifter the drive. One can easily see that by setting the catch for the lifter plate it is possible to accelerate or lessen the revolutions of the bobbins.

Intermediate Frame. By the frame we have examined, the slubbings have been drawn and twisted, and wound on to bobbins; now we take them to the frame called the intermediate [85]. Excepting that a creel of bobbins sits on the frame instead of the cans behind, and that the bobbins on which the yarn is wound are smaller, this frame differs in no way from the slubbing frame. Our illustration is taken from the latest and most improved pattern, made with Short's or Mason's collar, cone-strap tightening apparatus, Curtis and Rhodes' patent winding motion, locking apparatus to the knocking-off motion, suspended pedestal to the end of the pulley shaft, a brake to the fly-wheel, a disengaging motion to the bobbin shaft and lifter shaft, single and double cone, and other added patents. From the bobbin [83] the effect of the intermediate frame on the yarn can be plainly seen.

Roving Frame. The roving frame is the next machine. It is finer, and altogether a higher mechanism than any of the frames preceding, though the principle of its working is the same. As many as 160 spindles sit on one roving frame; the bobbins are short and small, and the thread is fine [84]. When we aim at yarns above 200 counts, a second roving frame should be called into action. We should now have an idea of the exact count of our yarn. Of course, the underlying hypothesis of all our work has been that we knew from the beginning; but sometimes fact contradicts theory. At any rate, we now begin to give the threads a definite name, and speak of a 20-hank, 30-hank, or 40-hank roving, by this meaning that so many hanks of 840 yd. each will go into

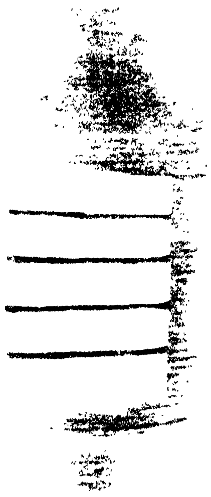
1 lb. weight. A 40-hank roving is very fine, and is generally spun into the highest counts.

Wool. When studying worsted drawing we stopped at the end of what is called the *first drawing-frame* because on the second the bobbin and flyer is used. There are other reasons. In no textile process is the practice more diverse. For long wools some manufacturers use six drawing-frames, two with faller gills and four with drawing rollers; others carrying through four drawings with the gills and two with the rollers. Again, for the shorter worsted wools there are yet two other methods at least, and upon these many variations are worked. Taking what is called the English method, we have nine drawing operations, which we shall detail hereafter. The second is the French method, coming gradually into use with us, and involving totally different machinery.

Gilling Frame. Returning now to the English method of drawing long wools, we note the special characteristics of the *second*, or *spindle* gill-box. Here the slivers are carried on combs, but there must be no draft on the sliver from the combs, the whole draft being in the rollers. From the delivery rollers the slivers, or *slubbings*, as they should now be called, are wound on to bobbins by the method before described. Adopting the most recent practice, we shall now discard the combs, and use only drawing rollers, the bottom rollers of each pair finely fluted, and the top rollers leather covered. By differentiated speeds the drawing rollers on what is named the four-spindle box elongate the fibres, and deliver to the bobbins a finer thread, which gets another little twist from the flyers. Refining still further, we pass the slubbings through the six-spindle weighing-box, the three six-spindle boxes, and the *dandy* roving-boxes. In the condition they leave the last, the slubbings, or rovings, are ready for the spinning frames.

Finest Worsted Drawing. Fine Botany wools, and wools of the best class, demand a treatment more prolonged. The system usually comprehends nine operations, which, as the mode of working should now be fairly clear, we shall merely enumerate. We operate (1) with two double-can gill-boxes; (2) with two two-spindled gill-boxes; (3) with four-spindle drawing-boxes, with bobbins 14 in. high by 8 in. in diameter; (4) with a six-spindle weigh-box, with bobbins same as last; (5) with an eight-spindle drawing-box, with bobbins about 7 in. in diameter; (6) with two eight-spindle drawing-boxes, bobbins 12 in. by 6 in.; (7) with two 24-spindle finisher-boxes, bobbins 9 in. by 4½ in.; (8) with reducers, with bobbins 6 in. by 3½ in.: and (9) with 30-spindle roving frames, with bobbins 5 in. by 3 in.

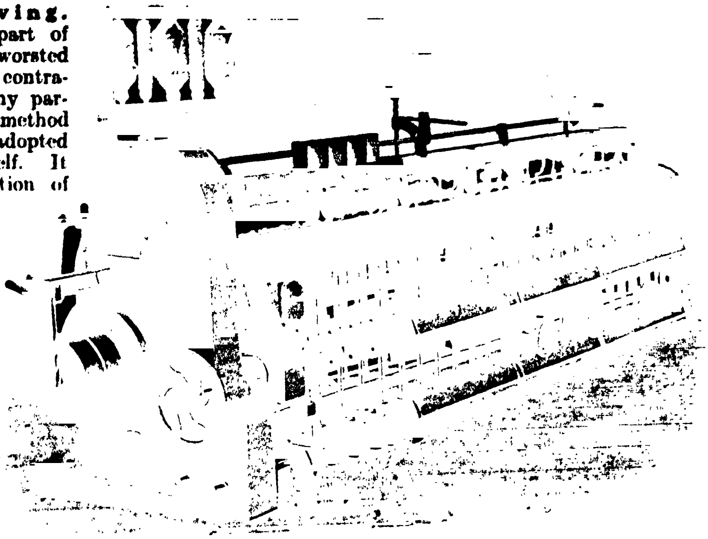
Both the first gilling machine [86] and the second gilling machine [87] are common to all methods of worsted drawing. The student will see from the illustrations the gradual advance in refinement and complexity.



82. COTTON YARN AFTER SLUBBING

83. COTTON YARN FROM INTERMEDIATE FRAME

84. COTTON AS IT APPEARS AFTER ROVING



85. INTERMEDIATE FRAME

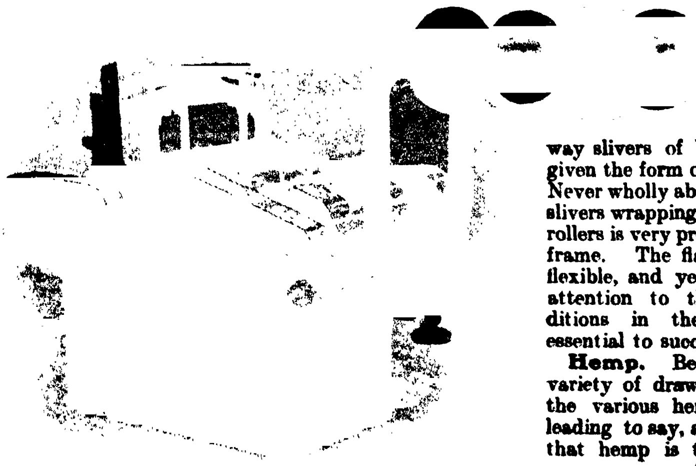
French Drawing. Though an integral part of the French system of worsted manufacture, which contradicts our own in many particulars, the French method of drawing has been adopted by some firms for itself. It is a curious combination of the waste-silk filling-engine, the drawing frame, and the condensers, and possesses features of some value [88]. The balls of sliver are brought from the gill-boxes, and hung two by two on the frame. The doubled slivers are passed into the back rollers, thence over a porcupine roller covered with little steel spikes set so as to lift the wool a little above the point of delivery of the back rollers. By this means the slivers are combed and drawn while being carried forward to the drawing rollers.

Having been thus drawn, the slivers now come in between a pair of rubber leathers. The rubber leathers are curiously constituted, being two pairs of rollers, an endless band of leather stretched round each pair, just like a feed lattice. The lower roller of the upper pair and the upper roller of the bottom pair, revolving in the same direction with an oscillating horizontal motion, make the leathers act as rubbers on the slivers passing between them. Rubbed into the semblance of a thread, and with a certain amount of added strength, the slivers are wound on to horizontal bobbins, which move to and fro, taking on the wool in spiral rounds, and building up an even spool.

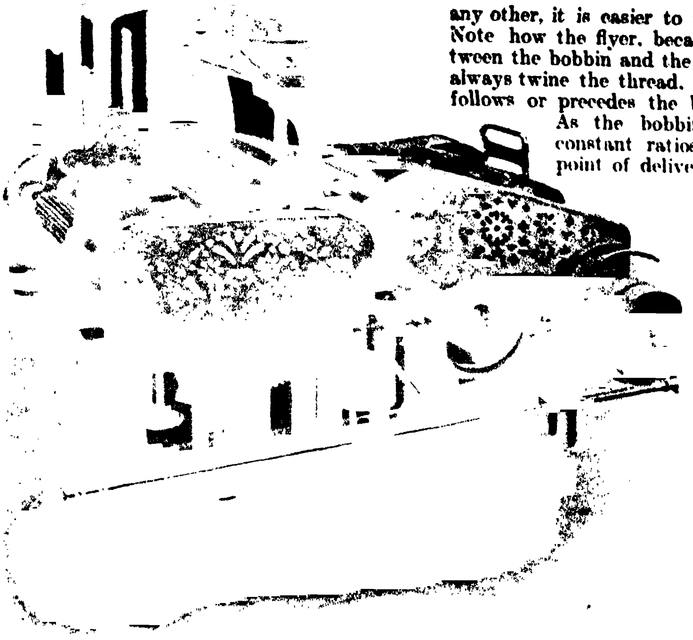
By repeated operations on machines of similar model, the sliver is at last formed into a fine thread, and prepared for the spinner.

Flax. The four drawings to which the flax sliver is usually subjected in linen manufacture have reduced it to fineness, cleanness, and uniformity. We must now get a twist on the weak rope, and have it put on bobbins. The roving frame differs only from the last drawing frame of the linen factory in one particular. Instead of the sliver delivery, we have the bobbin and flyer arrangement at the end of the frame. As we form the rove by one operation, there is no doubling at this frame. The sliver is fed singly into the rollers, drawn out and carried forward by the gill combs, and sent out by the delivery rollers to the flyers, which twist and wind it on the bobbins. In this way slivers of both line and tow are given the form of yarn we call *rovings*. Never wholly absent, the danger of the slivers wrapping themselves round the rollers is very pronounced at the roving frame. The flax must be kept soft, flexible, and yet not damp. Careful attention to the atmospheric conditions in the preparing-room is essential to success.

Hemp. Because there is a wide variety of drawing machines used for the various hemps, it would be misleading to say, as has often been done, that hemp is treated in exactly the same way as flax. Some machines which are employed on the drawing



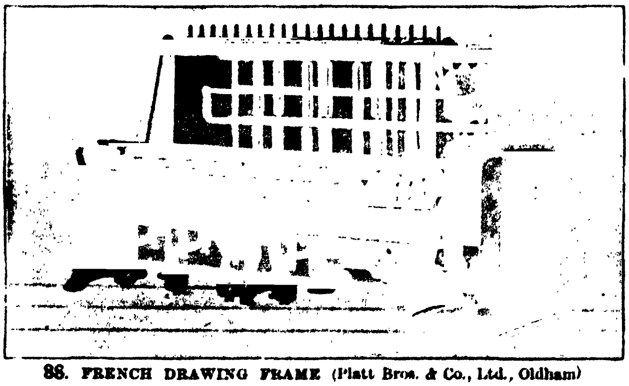
86. FIRST GILLING MACHINE (Taylor, Wordsworth, & Co., Leeds)



87. SECOND GILLING MACHINE (Taylor, Wordsworth, & Co., Leeds)

of manilla and sisal hemp are never seen in a linen factory. The fact may be put in this way. Whatever drawing frame has been used for preparing the sliver may be employed for the roving, with the addition of the bobbin and flyer. For coarse twines and the yarns of low quality ropes a long double drawing frame, with a bobbin and flyer at the end, is frequently employed. The higher qualities of common hemp are drawn and formed into rovings with the same elaboration as flax, and generally on the same machines.

Jute. We saw that the jute drawing frame had four gill-combs on each bar—on each bar of the roving frame we have eight—it is therefore easy to appreciate the difference in the fineness of the gill teeth. The rest of the machine is in equal proportion. The slivers have been drawn on the second drawing frame to a fineness of, say, 45 yards to the lb.; they are fed singly into the roving frame, eight slivers to each carriage, and drawn through to the flyers, which twist and wind them on to bobbins. If the roving frame has a draft of 7 to 1, the roving will be refined to a thread giving over 300 yards to the lb. The high counts of cotton rovings are exactly 100 times finer. As the jute frame is so much larger than any other, it is easier to watch its operations. Note how the flyer, because it interposes between the bobbin and the drawing rollers, must always twine the thread, no matter whether it follows or precedes the bobbin in revolution. As the bobbin grows in size the constant ratios of speed keep the point of delivery always equal.



88. FRENCH DRAWING FRAME (Platt Bros. & Co., Ltd., Oldham)

Electric Stop-Motion. No drawing frame of any class is without a stop-motion of some sort. In its earliest form, the stop only operated on the feed side, but later invention brought the delivery rollers also under its regulation. Each machine maker has his own patent, but the idea is the common property of the textile industry. The principle admits of general application, and by a variety of instruments. A fork, spoon, tumbler, or bar is adjusted to the sliver feed or yarn delivered, so that in case of break, attenuation, or other defect occurring in yarn or sliver, a lever, spring, or clutch acts upon the driving pulley, and throws it out of gear. An Accrington man conceived the idea of making the stop-motion merely the medium of the electric current which would stop the frame, and the idea has been successfully applied to frames of all kinds. From a small battery at the side of the frame, the current is carried to the rods which form, with the stop-motion parts, the electric circuit. When any disturbance occurs, the part affected touches the electric rod, completes the circuit, and stops the machine.

CHEMISTRY

16

(Continued from page 2084)

THE NEW THEORY OF MATTER

The Electricity of the Atom. An Imaginary Atom.
Experimental Atoms. Chemical Union Explained

By Dr. C. W. SALEEBY

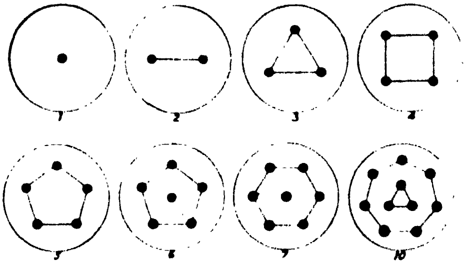
THE root question of chemistry is the nature of matter, and we have already seen that while matter has the habit of existing in the form of atoms, these are elementary only in the sense of the older chemistry. Plainly, we must proceed to dissect them. Now, atoms are not mere aggregates or heaps or accumulations of simpler components—one atom, let us say, consisting of half a dozen, and another of ten. An atom, like a man or a society, is not an *aggregate*, but an *integrate*—that is to say, is not a *heap*, but an *organism*. A heap of stones is an aggregate, the cathedral which may be composed of such a heap of stones is an integrate, and it is not without reference to this analogy that we have had occasion to liken an atom to St. Paul's.

The Anatomy of the Atom. In discussing, then, the anatomy of the atom (the reader will observe the interesting contradiction in terms—the cutting up of the uncuttable)—in discussing the anatomy of the atom, we have two distinct problems. The first is to ascertain the nature of the units which compose it, their different kinds if they be of different kinds, and their characters; the second is to ascertain their relations to one another—with this noteworthy complication, that these relations are not permanent and changeless, such as the relations of the stones in a building, but are constantly undergoing rearrangement, which strongly suggests the evolution of thoughts and feelings in the mind of man, or the evolution and molecular change that is to be found in a living cell.

On account of reasons which will probably make themselves evident, we may begin with the second problem, towards which we are more directly led by our previous study of the older chemistry. For the moment we shall ignore its more difficult part—the question of the changes of relation that constitute the evolution of an atom. Admitting that such changes occur, we may ignore them and confine ourselves at present to a study of the relations between the parts of an atom as they are believed to persist for long periods—perhaps thousands or millions of years in the case of the lighter and more stable atoms. It would obviously be premature at this stage of our exposition to tackle directly such a complicated question as that of the birth of the helium atom from the atom of radium. But the reader is already aware that we have identified bodies which we may call electrons or corpuscles, and of which atoms are composed, in part, at any rate. In the case of radium, we knew them at first as the *Beta* rays, and their distinctive characteristic is that they carry a charge of negative electricity.

The Electricity of the Atom. For the present we need no more facts save to remember that if these negatively charged corpuscles are to live together so as to constitute an atom, there must be some bond of union between them. "Like electricities repel"; one negative corpuscle will not be reconciled with another unless there be "positive electricity," so-called, which will master them both. We may thus assume, according to the teaching of several students, the first of whom in our time was Lord Kelvin, whilst the chief worker is Professor J. J. Thomson, that an atom is an area where there is positive electricity of such an amount as will balance—as will exactly balance, if the atom be stable—the sum of the negative electricity of all its constituent corpuscles added together. We might assume that the atom was a flat object, that all its electrons lay in the same plane; but it is more satisfactory, and doubtless much more nearly true, to assume that the atom is spherical, and has, in short, a tri-dimensional character. For the present we will make this assumption; but the reader must on no account allow himself to be persuaded that atoms are asserted to be really spherical. The sphere, however, is the simplest figure that we can choose if we are to abandon any attempt to represent the atom as a flat object, and the sphere is, beyond a doubt, much nearer the truth.

An Imaginary Atom. Now, Professor J. J. Thomson's inquiry is this: Assuming that the atom is a sphere of positive electrification, in which lie a number of negatively electrified bodies, how would they tend to arrange themselves, and what would be the consequences of their arrangement? In order to simplify our problem we must assume—and never forget that we have only assumed it, not proved it—that the electrons, or negatively electrified corpuscles, are at rest. We have, of course, every ground to believe that they are by no means at rest, but we must attack the simpler question first. Again, it is believed that in the case of the simplest known atom—that of hydrogen—the number of electrons, or negatively electrified corpuscles, must be from 700 to 1,000; but, plainly, we cannot begin with such figures, and must consider what would happen in the simplest conceivable cases. The simplest of all is that, of course, in which there is only one negative electron, and that exactly balances the positive electrification of the atom. In such a case, the negative electron would lie at the centre of the sphere. If there were two corpuscles, they would be balanced with themselves, and with the positive electricity—that is to say, the atom could exist as a stable object, assuming that no outside force interfered with it—on condition that they were placed upon a diameter of the sphere at points exactly midway between the centre and the circumference. If there were three corpuscles, they would have an equally simple arrangement, forming an equilateral triangle, symmetrically arranged about the centre of the sphere. If there were four corpuscles, they would form a square ; five would form a pentagon. And at this point we begin to reach a marked difference. We might expect that, if the number of corpuscles were increased, they would behave just as they do when the number is so few—that is to say, they would arrange themselves in a continuous figure just as if they lay on the surface of a smaller sphere placed within the sphere that constituted the boundary of the atom ; but, indeed, they would not, and cannot.



ELECTRONS IN THE ATOM

Not so Simple as it Looks. Such an arrangement would appear satisfactory, since it might be supposed that the whole structure would be balanced by the positive electricity and the negative electricity, thus having what looks like a symmetrical arrangement. Supposing this were so, the difference between a heavy and a light atom would depend simply upon the number of the corpuscles that constituted it, and the difference in the relations between the corpuscles would simply amount to this : that in the lighter atom they were less crowded than in the heavier. There might thus be a perfectly regular arrangement ; there might just as well be an atom containing 937 corpuscles as one containing 938. One would not be more stable than the other, and the properties of the two would differ in the infinitesimal degree which the difference in their structure would require.

But if we look at the list of the elements arranged, let as say, in order of atomic weight, we find no such simple sequences. There is not a uniform measure of increase in weight as we ascend the list, nor is there a uniform change in the properties of the elements represented. The pre-eminent feature of such a table, as we have again and again insisted, is that it is *periodic*. Groups of characters come and go, and come again. There is a more or less regular recurrence of them. That is the whole meaning of the term "periodic law."

The Survival of Atoms. Now, Professor Thomson has shown that directly the number of corpuscles increases beyond five in the model atom we have imagined, a new kind of arrangement is met, and the result of his mathematical inquiries, together with certain experimental facts, and together with the known facts of the periodic law, leads us to the conclusion that systems such as we have imagined are stable only under certain conditions. For instance, if there were 938 conpuscles in such a sphere, it might be stable ; but if by chance it lost one, the 937 could not arrange themselves in any stable fashion. It might be necessary for 21, or any other number of additional corpuscles to be lost before a stable structure could be possible. Is it not more than probable that the gap between, let us say, uranium and radium, or lead and silver, is capable of some such explanation as this ? And here, again, we may discern a new meaning in the assertion which we made in a previous chapter as to the possibility that Empedocles was right, and that the law of natural selection, or the survival of the fittest, is true of atoms as well as of living things.

Brief Life of the Atom. We remarked that the reason why there is so very little radium in the world is that its atom is unstable ; it can survive for only a brief time, so that many specimens of it cannot accumulate. It was further asserted that we must now regard the 75 or 80 different kinds of atoms with which we are acquainted as the relatively stable survivors from an infinite number of conceivable atoms, most, or indeed all, of which may have momentarily come into existence again and again, but have been unable to survive. It is believed that the number of electrons in an atom of mercury is about 200,000, and those in an atom of radium about 250,000 (perhaps more nearly 225,000). Why, then, should there not be at least 225,000 or 250,000 elements, if it be not that the laws of atomic structure permit only 75 or 80 to survive ?

Professor Thomson has shown that instead of one ring or sphere of corpuscles, two are necessary directly we go beyond the number of five [see illustration]. Of these, one consists of fewer corpuscles than the other and is nearer the centre ; throw in a few more, so to speak, and three groups are required, later four, and so on. It has been said that we conceive of the atom as having three dimensions, but it is possible to make most interesting experiments of the highest illustrative importance and having strict accordance with Professor Thomson's calculations from purely abstract considerations, if we are content for the moment to conceive of the atom as two-dimensional or flat.

Experimental "Atoms." The experiment was devised by Professor Mayer. First, a surface of still water represents the plane of the flat atom. Each negative corpuscle is represented by a little magnetised needle which is made to float by being thrust through a piece of cork. The needles are all arranged so that the negative poles are uppermost and the positive poles below. The negative poles behave to one another as the corpuscles of an atom must behave to one another, tending to repel one another with a force varying according to the law which is now so familiar to us—the law of inverse squares. Now, some arrangement has to be provided to represent the positive electricity which holds the atom together, and this is easily done by a positive magnetic pole which is hung over the water.

Supposing we start with one needle; it is immediately fixed under the magnet. Throw in another. The first moves from its original position, and the two assume the positions we have already defined; and so on through the triangle, the square, and the pentagon until, when a sixth needle is thrown in, we find not a hexagon but a pentagon with one needle in the middle of it. Later on, two go to the middle, then three, forming a triangle; then there is a square, a pentagon, *and so on and so on* [see illustration]. We must closely recognise the significance of this. Here is the periodicity which the other arrangement—now proved to be impossible—did not display, the periodicity which the periodic law demands. For observe what happens, supposing we strip off the outer ring and leave an inner triangle [see 10 in illustration]. Plainly, we have an atom such as one we have already seen. Plainly also, the fact of the triangle will tend to make the larger atom resemble, in some degree at any rate, the smaller. Perhaps the one stands for chlorine and the other for bromine. And another fact needs almost equal emphasis. It is the sudden transformations of the entire grouping which may be caused by the insertion of one needle more; while if yet another be added there may be little modification. It just takes its place in the outer ring. That is true, for instance, if the numbers be 16, 17, and 18, but if one more needle be thrown in, the whole structure is changed and, as it happens, the change is still more marked when the twentieth is thrown in. Supposing we multiply all these figures by a few hundreds we can now readily understand how it is that numbers of corpuscles intermediate between the figures so obtained could not form a stable atom at all. They might make a momentary attempt to form an atomic organism amongst themselves, but it would immediately collapse.

Movement of Electrons. The complication introduced by the fact that the electrons must certainly be conceived as in motion is not so serious as would appear. We can imagine these various rings in a state of rotation around the centre of the sphere, without the grouping of the corpuscles being altered. The complexity introduced by the fact that Mayer's needles are in a plane, while the corpuscles of the atom must have a tridimensional arrangement, is much more serious, but it is by no means insuperable. Already, Professor Thomson has succeeded in his initial attack upon it and, so far as the plane arrangement is concerned, or the arrangement in rings rather than shells, he has shown how such corpuscles must be arranged up to numbers well on the way to a hundred.

Application of the Theory. Let us now see what facts this new theory of the structure of matter enables us to understand, premising most clearly that we are by no means attacking the ultimate question yet, but have merely advanced our problem from the stage in which the properties of the atom seemed to be entirely mysterious to a further stage in which they seem to be more or less intelligible—both stages being no further than atomic, however. We are very far indeed yet from considering the further question which must face us afterwards. But taking the subject at this stage, let us see which of the properties of matter we can explain, confining ourselves for the purposes of the present course to those properties which may be called more distinctly *chemical*.

In the first place let us take valency, the curious property of atoms in virtue of which they seem to have a varying number of arms, while the newly discovered group of inert atmospheric gases have no arms at all. When we come to study the behaviour of Mayer's needles or of the negative electrons which we have conceived, according as 13, 14, 20, etc., of them are organised within one area of positive electrification, we find an intelligible explanation for, at any rate, the main facts of valency, and are not without prospect of explaining all the rest.

We find that when there are, let us say, 60 corpuscles in the organism of the atom —the reader, of course, understands that the figure is quoted merely "for purposes of illustration"—the addition of one more corpuscle does not fundamentally alter the structure of the atom. In another case it is similarly found that the subtraction of one corpuscle does not fundamentally alter the structure of the atom; or the atom may tolerate the loss or gain of two corpuscles or three, but no more.

Atoms such as the first we have supposed will be one-handed, the others will be two-handed, three-handed, and so on respectively. Thus, we may reasonably suppose valency in any case to be determined by the number of electrons which the atom in question can gain or lose without having its whole constitution altered—without, for instance, having to arrange its electrons into three groups instead of two, or five instead of six.

The No-handed Elements. The reader may ask what chemical differences correspond to the difference we have suggested by using the alternative "gain or lose," and we shall now see that the alternative corresponds quite satisfactorily to observed facts. But let us spare a word for the no-handed elements. Now it is the most remarkable fact that this zero group of elements fits as satisfactorily into Thomson's theory as we have already seen it to fit into the periodic law of Mendeleef. On the supposition already stated, the peculiarity of the particular numbers of electrons that compose the atoms of the members of this group should be that they cannot tolerate the loss or the gain of *even one electron* without losing their stability. Such a structure plainly will be without any combining power at all. Now, it is found that the arrangement of 59 electrons and also that of 67 is in this case, and it is surely very much more than a coincidence that seven atoms are possible between these two, and that seven atoms do in fact occur—lithium, beryllium, boron, carbon, nitrogen, oxygen, fluorine—between helium and neon, as also indeed between neon and argon. Thus, the theory provides a satisfactory explanation for valency and for absence of valency alike.

The Explanation of Chemical Union. This magnificent theory will also lead us to understand the fundamental facts of chemical union. Plainly, it would not be of very profound value if it failed to explain the most characteristic and abundant of all the facts of chemistry. For long years men have spoken of chemical forces and chemical affinity and chemical energy. The philosophic mind has always expected that some day these powers would be resolved and recognised as essentially one with the other manifestations of energy in the universe. The physicists long ago outstripped the chemists in a similar respect. They showed the identity of heat and energy of motion [see PHYSICS]. They showed the correspondence between heat and work, heat and electricity, and so on; and they framed, some half century ago, the great generalisation of the conservation, the convertibility, and the ultimate identity of all the forms of energy. Sooner or later the chemists had to fall into line with this doctrine—as, indeed, they did not hesitate to admit.

The Electrical Nature of Chemical Forces. Of recent years, evidence for the ultimately electrical nature of chemical forces has accumulated, and Professor Thomson now seems to have solved the problem altogether. The chemical elements are divided or classified according to their electrical properties, some being more or less markedly electro-positive, while others are more or less markedly electro-negative. If we look at a list of the elements we find that, let us say, No. 1 is what is called electro-positive, and so on increasingly till No. 8, which is still more so, whereas No. 9 is very electro-negative, and so on. There is not a continuously steady rise and fall in this electrical property, but sudden interruptions, and then continuous rise or fall for a time. Thomson's theory of atomic architecture completely explains this fact.

An atom with a certain number of electrons has, let us say, 15 in the outer ring and 10 in the inner. Now, according to mathematical theory, 10 is the smallest number for the inner ring that is compatible with the presence of 15 in the outer ring. Such an atom has, so to speak, no rope to spare. It is electrically unstable or electro-positive; add another electron, and it becomes very unstable or electro-positive; and then, at a certain point a totally new arrangement is reached, and the atom becomes very stable or electro-negative again. Well, let us suppose that sodium and chlorine atoms are placed in one another's company. The sodium atoms are electro-positive, and are readily capable of losing one electron apiece, being therefore also one-handed. The stability of the chlorine atoms, again, is compatible with the acquirement of one electron apiece. They are thus electro-negative and also one-handed. Obviously, the circumstances are fit for combination between these atoms and the compound sodium chloride will result, owing to an electrical attraction between the positive atom of the metal and the negative atom of the halogen. The electron which the one atom loses is conveniently accommodated in the other atom.

Explanations of Periodic Law. We have already insisted upon the importance of the fact that the arrangement of Mayer's needles—as experimentally observed, and as demonstrated about a year ago at the Royal Institution by Professor Thomson before the most illustrious audience which the present writer has ever seen there—that this arrangement has a definite law of periodic recurrence as the number of needles is increased. Purely abstract mathematical considerations have also demonstrated the necessity for this periodicity. At last we see why, on reading the table of the periodic law, we come at recurring intervals to elements that resemble one another. Whereas we find that No. 1 and No. 2 are dissimilar, No. 1 resembles Nos. 9, 16, and 23, let us say; while No. 2 resembles Nos. 11, 18, and 25. Thus we have groups such as lithium, sodium, and potassium; phosphorus, arsenic, and antimony; the group of the halogens, and so forth. While these resemble one another chemically when subjected to the ordinary tests, the physician can add the corroborative evidence that their actions on the human body display similar resemblances. The theory of Thomson fits in to a nicety with all these facts.

What One Electron May Do. Our imaginary atom with 20 electrons may have them arranged in an outer circle of 12, an inner of seven, and one central one, which has got as near as it can to the positive magnet as illustrated in Mayer's experiment. If another needle or electron be inserted, the whole arrangement may be completely altered. You get an atom of a totally different kind; which is to say that you get an element having totally different properties, as different, let us say, as the properties of sodium and magnesium—which follows it in the table of the periodic law. But when a certain number more be added, what we find is a reproduction of the original arrangement with the addition of an outer circle, representing the new electrons added. Plainly, the first arrangement suggests such an atom as sodium, the last arrangement such an atom as that of potassium, and the theory explains the similarity between the two; while the intermediate arrangement or arrangements represent the atoms of magnesium, aluminium, silicon, phosphorus, sulphur, chlorine; the unlikeness between sodium and potassium on the one hand, and all these other elements on the other hand, similarly made intelligible.

Value of the Theory. Indeed, this great theory co-ordinates and illuminates whole series of facts hitherto awaiting explanation. It is justly comparable to discoveries like those of gravitation, natural selection, the association of ideas, or the circulation of the blood. The discovery of the periodic law constituted an epoch in chemistry. It consisted in the observation, grouping, and correlation of a very large number of individual facts. It is really worth while to point out the remarkable correspondence between the work of Mendeleef in this respect and the great labours of Kepler. The astronomer spent years in observing the planets and finally deduced from them his three laws of planetary motion. They constituted an epoch in astronomy, but obviously neither the periodic law nor Kepler's laws constitute the final stage of the inquiry. In each case we must ask a further question: What is the explanation of the laws already ascertained? Why do the planets move in this fashion? Why do the elements display this periodicity? The Kepler and the Mendeleef are alike essential, but their work is completed and their labours crowned when a Newton arises to elucidate the greater law of gravitation, of which the laws of planetary motion are merely consequences, and a Thomson arises to elucidate the fundamental fact of atomic architecture, of which the periodic law is similarly only a consequence. Indeed, we are able to say that if matter be really made of electrons the atoms of the elements are inevitably bound to display that periodicity of properties which Mendeleef demonstrated but could not explain, just as Kepler demonstrated but could not explain the movements of the planets.

Further Proof. Every kind of confirmation that can possibly be suggested is being found to come to the service of what its author calls the corpuscular theory of matter. We have already mentioned facts of valency and of absence of any valency; the facts of chemical union; the facts of the periodic law; the facts of the grouping of the elements. To these we may add the facts of the triads of elements which were mentioned in a previous chapter. It was pointed out that in the case of chlorine, bromine, and iodine, for instance, or calcium, strontium, and barium, the atomic weight of the middle element stands almost exactly midway between the atomic weight of the first and third elements. It is an easy matter to study the groupings of small numbers of corpuscles as, for instance, 61, 41, and 25, and show that if these numbers be taken to represent atoms, the atomic weight of the middle atom is about half-way between the atomic weight of the first and third atoms. The three atoms closely resemble one another. The fact is explained when we look at the groupings. Twenty-five corpuscles form three rings, containing 13, 9 and 3; these three rings are found to recur when we take 41 corpuscles; there is merely a fourth ring of 16 added outside them. Again, they recur when we take 61 corpuscles, having this time not merely the fourth ring of 16, but a fifth ring of 20.

A completely different method of inquiry affords yet new confirmation to Thomson's theory. It is found that when the light emitted by any element in a glowing state is analysed by means of the spectroscope, constituting the process called Spectrum Analysis [see PHYSICS], definite and distinctive characters can be recognised as belonging to each element, such characters ultimately depending, of course, as we now see, on the structure of their atoms. Now if we take the spectra of a group of elements we find that they are related to one another in structure, and Professor Thomson has shown, by mathematical reasoning, that groups of electrons related to one another in the fashion indicated in the previous paragraph would necessarily produce related spectra of the kind actually observed.

Groups and Series. Reference has already been made to the fact, which we may well emphasise, that the electrical characters of the elements afford further confirmation of the theory. When elements are arranged in groups, as in the table of the periodic law, we may read the columns downwards, in which case, for instance, we get such a sequence as helium, neon, argon, krypton, xenon; or may read across, in which case we get such a sequence as that recently quoted, consisting of the seven elements that lie between helium and neon—*viz.*, lithium, beryllium, boron, carbon, nitrogen, oxygen, fluorine, these elements belonging respectively to groups one to seven. Such a sequence as this last constitutes what, in order to emphasise it, we call a *series* of elements as distinguished from a group. Now, a group consists of members which closely resemble one another, but we must recognise that there is also a relationship, though of a quite different kind, between the members of a series. This relationship is most clearly expressed in the case of the electrical properties of the elements already referred to, and corresponds in the most amazing way with the relationship which ought to exist if Thomson's theory be correct.

The Last Stage. Now we must ask the reader to recall certain statements which we made in introducing this part of our subject. The whole significance of Thomson's theory has not yet been stated. We have yet to apply it to the existence of unstable atoms and to see whether it explains their behaviour as well as it does that of the stable atoms with which we are now familiar. Furthermore, as has already been insisted, we have by no means pushed to the last stage our inquiry in what we call the root question of chemistry. It is all very well to speak of a sphere of positive electrification, for instance, but whence does it come? Of what, or in what does it consist? Similarly, with the negative electrons. When we discussed radium we spoke of the shooting out of some of these from the atom of radium. But if these things are the ultimate constituents of matter we must follow them and see what becomes of them.

THE BRAIN AND SPINAL CORD

Group 25
PHYSIOLOGY
16

Continued from page 2147

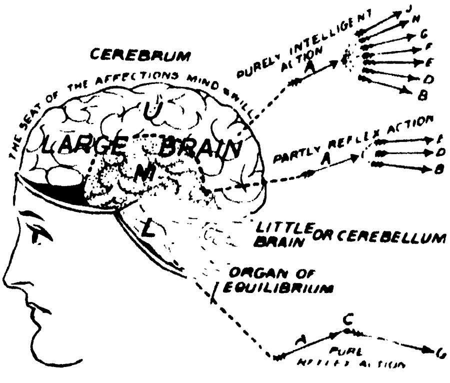
Five Divisions of the Brain. Centres of Spirit, Soul, and Body. Development of the Brain. Formation of Habits. Reflex Actions

By Dr. A. T. SCHOFIELD

WE have examined generally the structure and leading divisions of the central nervous system, and found that it may, like the liver, be conveniently connected with the number *five*. There are five divisions. In the cerebrum [122] we have the upper brain or hemispheres, the mid-brain, and the lower brain, or medulla ; also the cerebellum and spinal cord—five in all.

Each hemisphere has five lobes, and the brain has five ventricles, while connected with it directly are the five senses.

The next point is, as we have seen, that it consists generally of two parts—the grey matter which forms the outside of the brain and the inside of the cord, and the white matter which forms the inside of the brain and the outside of the cord. The grey consists of nerve cells forming the vital battery that energises the nerves, or wires, and discharges "vital" force. The white consists of nerves, which are the wires along which the impulses travel.



122. PARTS OF THE BRAIN
U. Upper brain *M.* Middle brain *L.* Lower brain, or Medulla *C.* Cerebellum

We will now consider the respective functions of the different parts, and will begin with the cortex and hemispheres.

The Seat of the Conscious Mind. The surface of the hemispheres, or cortex, is believed to be in a special way the seat of the conscious mind or spirit of man. The convolutions represent the extent of his faculties ; the more numerous and deeper they are, the more extended are these. It is probably here, too, that memory lays up her stores of knowledge. As actions arising from cortical excitement are voluntary and intelligent, and the direct result of the conscious mind, nowhere do we find greater evidence of the value of education than in this region. It is mainly composed of brain cells, though, of course, the nerve fibres are quite innumerable. These cells differ somewhat in appearance according to age. The diagram [123] roughly distinguishes their appearance in infancy, manhood, and old age. It will be seen that whereas the cells are *in infancy* blunt and only slightly pointed, and in many cases round, *in manhood*, after education and development are completed, they become sharp, with long processes, to which innumerable fibres are attached ; *in old age*, again, a good many of these processes appear to be worn off.

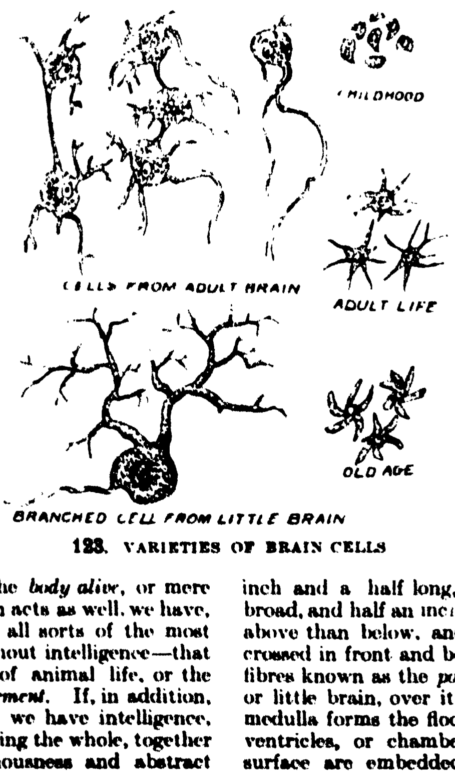
Effect of Education. The difference education makes in the brain is like that between an untrodden forest, such as that through which Stanley passed in Africa, and a civilised country. In the former we get a pathless, trackless wood, through which progress in any direction is made with the utmost difficulty ; in the latter, good roads, leading easily in any direction we wish.

The business of education is to construct these pathways or connecting threads of knowledge in the brain. This is still more strikingly seen as we proceed to the other brain divisions but is of great interest here.

How Knowledge is Acquired. When a child begins to read, certain brain cells receive from the eyes the letters H O T ; but it is a long while before connections are established with the various motor cells that enable the child at once to say "Hot" whenever it sees these letters, and by certain connection with these higher centres to form the idea of burning and heat at the same time. A person bereft of these convolutions in the upper part of the brain might be able to read "Hot," but could not understand what he read. The more a child's higher faculties of thought and reason and memory are exercised, therefore, the more (within reasonable bounds) pathways of knowledge are formed through this brain forest, and the easier does learning become ; and thus in after-life the man's brain power is enormously increased by a varied and liberal education.

What Occurs on Removal of Upper Brain. The following painless experiment, showing that the cortex of the brain is the seat of intelligence, is well described by Professor Huxley : "If a frog be narcotised, and its convolutions removed (being the upper division, but the middle and lower divisions left), the animal sits on the table, resting on its front limbs in the position natural to a frog, and breathes quite naturally ; when pricked behind it jumps away, often getting over quite a considerable distance; when thrown into water, it begins at once to swim, and continues swimming until it finds some object on which it can rest; and when placed on its back, immediately turns over and resumes its natural position. Not only so, but the following very striking experiment has been performed with it: Placed on a small board, it remains perfectly motionless so long as the board is horizontal; if, however, the board be gradually tilted up so as to raise the animal's head, directly the board becomes inclined at such an angle as to throw the frog's centre of gravity too much back, the creature begins slowly to creep up the board, and if the board continues to be inclined will at last reach the edge, upon which, when the board becomes vertical, he will seat himself with apparent great content. Nevertheless, though his movements, when they do occur, are extremely well combined, and apparently identical with those of a frog possessing the whole of his brain, he never moves spontaneously, and never stirs unless irritated. If, however, only the upper part of the spinal cord be left, these movements cannot be performed."

Seat of the Animal Life. If the cortex, or upper brain, be considered as the seat of the *intellectual* life, or *spirit*, of man [**124**], the mid-brain is the chief seat of the *animal* life of man, or what is often spoken of as the *soul* ("The moving creature that hath soul"—Gen. i. 20, Marg.), while we shall be able to show that the lower brain, or medulla, is the seat of the *physical* life, or the functions essential to the *body* life. If the lower brain, or medulla, acts alone we have just passive physical life-breathing and the beating of the heart, etc., going on, but no movements—*i.e.*, the *body alive*, or mere *existence*. If the mid-brain acts as well, we have, in addition, movements of all sorts of the most active description, but without intelligence—that is, the full manifestation of animal life, or the *soul and body alive*, or *movement*. If, in addition, we have the highest part, we have intelligence, or reason, directing or guiding the whole, together with the power of consciousness and abstract thought, and the *spirit, soul, and body* alive.



128. VARIETIES OF BRAIN CELLS

Illustration of Functions of the Three Brains. Now to illustrate this. Take the case of a person reading a book aloud and understanding it. He comprehends, and probably reads it by the action of his intellectual life, or *spirit*; he holds it in his hand by the action of his animal life or *soul*; and he gets the breath to read it with from the action of his passive physical life, or *body*.

If the highest centres be paralysed, he ceases to read, but still holds the book and breathes. If the middle part then be paralysed he drops the book, but still breathes. If the lowest part then be paralysed, he dies.

Effect of Alcohol. The three divisions are also well illustrated in the phenomena of drunkenness, for alcohol paralyses the brain *in this very order*.

First the intellectual or rational life goes and the animal life is left without reason to guide it, so that the man jumps about, laughs, and sings, without any reason to guide him. If he takes more of the poison, the mid-brain is paralysed, and he becomes "dead" drunk. He falls down, and no longer uses his animal life, or moves any limb, but he still breathes. If someone now pours more down his throat, the lowest part, or medulla, is paralysed, and he dies.

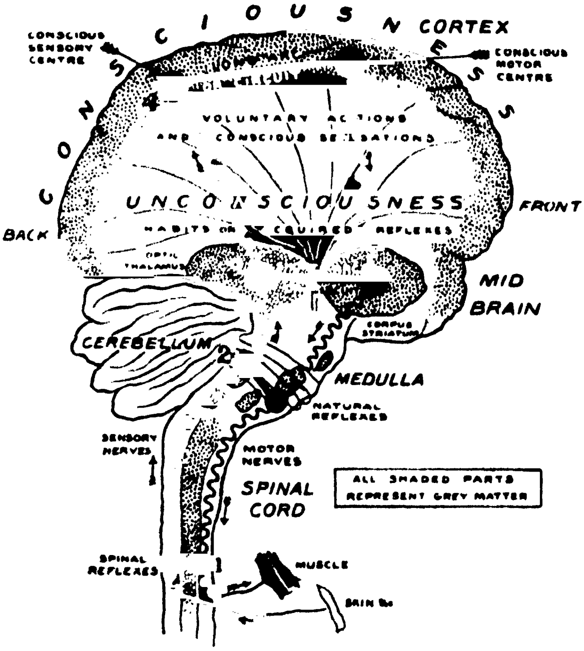
We get in this mid-brain the centres of sight, hearing, taste, sense, and speech—at any rate on their mechanical side. The two pairs of large bodies—the corpora striata and the optic thalami—situated here are believed to be the centres respectively of mere motion and sensation of any part of the body; the centres for intelligent action or feeling being of course in the cortex. The mechanism of the movements of this part will be considered a little further on.

The Brain that Works Unconsciously. The lower brain, or medulla oblongata, is the centre of the passive or inner life of the body. We will recall a few of its features. It is the upper expanded part of the spinal cord within the brain, just beneath the cerebellum, or little brain. It is an inch and a half long, three-quarters of an inch broad, and half an inch thick. It is much broader above than below, and at the upper part it is crossed in front and beneath by a broad band of fibres known as the *pons varolii*; the cerebellum, or little brain, over it forms the roof, while the medulla forms the floor of the fourth of the five ventricles, or chambers of the brain. In its surface are embedded, one on each side, two rounded bodies the size and shape of olives. They are called the *olivary bodies* [pages 2144-6].

The medulla is, of course, largely composed of white nerve fibres passing up to the brain, but it is also the controlling centre for the most important and vital actions of the body. Here is the centre that controls *respiration*, that controls the *swallowing of food*, the power of mastication or chewing, the *formation of saliva*; every one of these so far, it will be seen, is connected with the supply of food to the body. It is also the centre for *regulating the action of* *the heart*, and the *size of the blood vessels*, especially of the skin. Under fear or cold it contracts them, and we become pale; under shame or heat it expands them, and we blush. It also contains centres for *regulating the size of the pupil of the eye*, for *taste*, and for *hearing*, and for some of the mechanism of *speech*. The medulla, together with the cord, is the centre of what is known as pure reflex action.

Why We Yawn. Nerve currents from the lungs and other parts are sent to the medulla when the blood contains too much carbonic acid; the blood itself circulating in the medulla also irritates the respiratory centre so that a reflex action occurs and force is transmitted to all the muscles concerned, causing a deep inspiration to purify the lung. This automatic—or more properly reflex—action may easily be proved by experiment. It is called reflex because it is, as it were, reflected back again, like a ray of light from a mirror.

If you drop a penny in a slot in an automatic machine, a box of matches is deposited in a little drawer, or a cigarette rolls out. This is a reflex action. The machine requires no mind or will. Mechanism is arranged in a certain way so that the weight of the penny must always produce the same result. If you pull the string of a shower bath, a stream of water descends. This is also a reflex action. No reflex action in the body is really so purely mechanical as this, but the illustration serves.



124. DIAGRAM OF THE BRAIN AND ITS VARIOUS REGIONS

The Medulla an Automatic Machine. The action of the medulla is under the control of the unconscious part of the mind, and it is therefore closely connected with the sympathetic system, which acts entirely without our knowledge. Of course, the value of this sort of action is immense. Were it not for automatic machinery, a man would have to be stationed by each box to hand out the matches or cigarettes as the pence were dropped in. Were it not for this system, life could not go on, for we could never carry on the processes of life as conscious and voluntary acts with the regularity and accuracy they require. We shall see the great value of reflex actions again.

The cerebellum is the site of the organ of equilibrium, and enables us to stand erect. It thus co-ordinates, or causes to act together, certain groups of muscles for this purpose. When diseased or paralysed, as by alcohol, a man can no longer stand upright.

Certain parts of the brain are specialised for a particular function, and the brain never acts together as a whole. The faculty of speech, on account of the interest which attaches to it, is a very good illustration of this fact.

The Centre of Speech. The centre of speech is situated just above and in front of the *left* ear. It is not on the right side at all. Here is the part that enables us to utter our thoughts, and from which power is given to the centres for the muscles of the mouth, throat, and tongue to formulate ideas into words. A blow here, of sufficient violence, perhaps depressing the temporal bone, or a disease of this part inside, would render a man speechless, whereas the same blow on the right side would have no such effect. But a blow of this force would most likely be followed by a further effect. The nerves of the body, as they travel to the brain, cross over from left to right, and right to left. So that the left brain, which is far the more developed, rules the right half of the body, including the right hand.

How the Right and Left Halves Differ. A blow of sufficient violence to injure the centre of speech would probably also paralyse the right half of the body, including the arm and leg. It is therefore a rule amongst medical men that if a man be paralysed down the right side, he is probably speechless as well. Whereas, if he be paralysed on the left side, his speech is uninjured, because then the injury is on the right side. But there is a remarkable *exception to this. Certain people in the world are left-handed.* That is, all that other people can do with their right hand they can do with their left. This is not the result of bad training, but it is *from birth*. The reason of the difference is that the two sides of the brain are transposed; the *left* brain is on the *right side*, and the *right brain* on the *left*. One finds, occasionally, the heart on the wrong side of the body in the same manner.

Now, these left-handed people, having their brains transposed, speak from the right side of the head, not from the left. If a violent blow be struck them on the left temple the right side of the body may be paralysed, but they will be quite able to speak; whereas, a blow on the right temple will not only paralyse the left side, as it does generally, but it will also render them speechless. There is one more curious fact as to speech. People who have been known to have the centre of speech incurably diseased or injured on the left side, may, after some time, slowly regain the power of speech and begin to talk again. It is believed that the right brain is, to a great extent, held in reserve to supplement the left, and that in such cases the right side slowly and gradually takes over the duties the left can no longer perform.

Functions of the Spinal Cord. Passing on now below the medulla, the functions of the spinal cord are of great interest, and are very varied in character. The *three chief functions* of the spinal cord as a nerve centre are (1) *conduction*; (2) *reflex sensation*; and (3) *reflex action*. In the previous section, from a different point of view, I have grouped the two reflex functions together, and added trophic and transferent functions, thus making four.

The spinal cord consists, as we have seen, of *a right and a left half, joined in the centre by a bridge of grey nerve matter.* A section of it in *any part shows that, unlike the brain, it is white outside and grey within, the grey matter consisting, as I have said, largely of nerve-cells, and the white matter principally of nerve-fibres.*

Nerves, when they pass into the brain or spinal cord, lose their sheath and white substance, and only the centre wire or axis cylinder is continued.

If any of the spinal nerves be cut across, both motion and sensation in the parts they supply are completely lost.

1. CONDUCTION. The spinal cord, then, is largely made up of fibres that conduct impressions or impulses either of sensation up the cord to the brain by the posterior part, or of motion from the brain down the cord by the anterior part. The *sensory* nerves cross over to the opposite side of the cord as soon as they enter it, the *motor* fibres do so before they leave the brain in the medulla oblongata; so that the right half of the cord contains the motor fibres of the right half of the body, and the sensory fibres of the left half, and vice versâ.

2. REFLEX SENSATION. A good instance of this is when disease of the hip occurs, and the sensation of pain is felt in the knee. The sensory nerves of the hip and knee both run to the same part of the cord, and the sensation from one part is reflected to another.

3. REFLEX ACTION. This is like that of the medulla, an action absolutely outside consciousness, and the necessary result of a certain irritation.

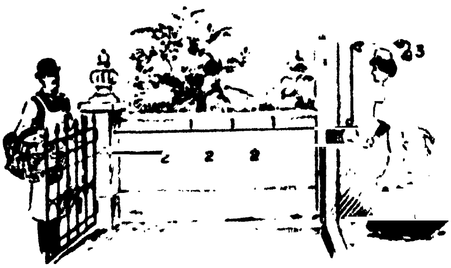
Movements may even have a definite purpose, like the beating of the heart or breathing, and yet be reflex, and without any exercise of conscious mind. Purpose in reflex action does not so much show the intelligence of the creature as of the Creator. One of the best instances of reflex action in the spinal cord is the knee-jerk, when one leg is crossed over the other, and allowed to hang loosely down. If the knee be struck with the edge of a book, or of the hand, the leg is at once kicked out, not only without the wish of the person, but even against it, so that the strongest will cannot prevent this reflex action from taking place. That this action is produced by the spinal cord is clearly proved, because, if it be diseased at a certain part, the leg no longer moves, however violently the knee be struck.

Conversion of Conscious to Reflex Action. We have already seen instances of natural reflex action, and of what importance they are to us. So valuable are they, indeed, that during the whole of our lives we are increasing the number of such acts; doing more and more complex movements without the aid of consciousness, and thus adding to those reflex acts which are born in us numbers of others which are artificial or acquired. It is probable that, as the lowest part of the cerebrum is the principal centre for *natural reflex action*, and the highest part for purely intellectual or voluntary or *intelligent action*, so the mid-brain is a great seat of *actions* once voluntary, but which have *become reflex*.

At first, nearly every action is the result of direct will and mental effort. Watch a child learning to walk. It is as hard as learning Greek is to us; each step is considered and taken with great difficulty. In six months, however, it has so become a matter of habit as to be reflex—that is, to be conducted outside conscious will action, and the cortex is set free from thinking *how* to walk, which absorbed it at first, to consider *where* to walk to, or to intelligently direct this new reflex habit. The same occurs with reading and writing, and every other oft repeated act. At first, all the mind is concentrated on *how* to read and *how* to write—*what* is read or written is of small importance. It is the connecting of certain letters with certain sounds, and certain sounds with certain shapes, that is at first such a severe mental effort; and yet so easy does it become by frequent repetition that after some time we never think of the separate letters, even when we write them, but writing and reading become acquired reflex habits the mind being wholly absorbed in what is read or written. The habit of swinging the right arm forward with the left leg, and the left arm forward with the right leg is so strong that it is the hardest thing in the world to swing the right arm and leg both forward together. It is, indeed, almost impossible, although we think we have complete control over the muscles of our limbs.

Acquisition of Good and Bad Habits. This leads us to another point. A natural reflex action *cannot* be overcome; an artificial reflex habit can be overcome, but it is *very hard*. Swearing, for instance, soon becomes an artificial reflex habit and the mind never thinks of it at all. An oath comes out at slight provocation, and we may not even know that we have sworn. To break such a habit is very difficult, and once we have allowed an action to become a reflex habit, it is the hardest thing in the world to conquer. Let us give here a favourite illustration of this [125].

Houses with long gardens in front have often latched gates by the road that can be opened by pulling a handle in the hall, which raises a latch by a wire running down the garden and saves a long walk along the path. The front-gate bell also rings in the hall. Now, if the gate bell rings, it is just like a sensation reaching the upper brain from some part of the body. The mind at once is conscious of it, and attends to it, just as the servant comes into the hall, opens the door, and looks down the path to see who is at the gate, and thus she decides whether to open the gate or not. If she pulls the handle, and it lifts the gate latch, anyone may enter. So in the brain the message may be, "Someone is treading on my foot." The mind looks out of the windows (the eyes) to see. If it be a stranger, the order goes to the muscles, "Draw the foot away;" if it be a friend, the order may go to the muscles of the voice to say "Why did you do that?" Now this is a *voluntary* action in both cases. But suppose the servant be lazy or busy, and cannot be bothered by running to bells all day, and suppose she ingeniously connect the bell-wire with the wire that lifts the latch round a pulley in the hall. Now when the bell is pulled it does not ring, and the servant (the mind) can hear nothing (is not conscious of it), but the pull raises the latch of the gate and lets anyone in. This is how a voluntary act is changed into an artificial reflex habit. Now consider the advantage of this. The servant is free to do other work, there is no worry of bells ringing, there is no delay in getting in. Observe, on the other hand, the disadvantages. Anyone can now get into the house, for the servant has no control or choice in the matter,



125. ILLUSTRATION OF ACQUIRED REFLEX ACTION
1. Afferent wire, or sensory nerve 2. Efferent wire, or motor nerve 3. Bell, or conscious centre in brain 4. Pulley, or acquired reflex in mid-brain

Hence we conclude that nothing is of greater value than the formation of as many good habits, or acquired reflex actions, as possible; and nothing is more dangerous than the formation of bad ones.

Cause of the Growth of Habits. The artificial reflex habits of which we have just spoken are believed to be formed in the brain by the growth of nerve-fibres between groups of cells frequently used for the same purpose.

Thus *A*, *B*, *C*, and *D* are nerve cells. *A* moves the right arm, *B* raises the left leg. The habit of moving the right arm when the left leg is raised has been performed so often in walking that a connection has been formed between *A* and *B*, and the artificial reflex habit acquired of moving the two together.

C controls the thumb, *D* controls the movements of the finger. The two so often go together in the same position in holding a pen that a nerve connection has been set up between them, making the act of holding a pen an artificial reflex habit.

We have compared the brain to the dark forests of Africa, but may here give a more homely illustration. Across a common covered with gorse and heather, paths are soon formed between the cottages built at one side, the public house at another, and the school and the general shop somewhere else. These paths always lead in the directions most often used, so that it is much easier to walk in them than over the heather and gorse. Education not only stores our mind with knowledge, but makes certain actions in our life easy to us, by forming artificial reflex habits.

Difficulty of Eradicating Habits. Let a town labourer change places with a fisherman. The latter will sicken and die over the unaccustomed labour in town, while the town labourer will find the fisherman's work impossibly hard and dangerous, and the exposure will probably kill him. There are no connections in their brains between the cells that have to perform the novel work of the other. It is not really a question of physical weakness, but of want of acquired reflex habits.

This shows how important it is for everyone to enter his trade or profession early in life, and not to change it afterwards. Look at a girl learning a mechanical habit, such as knitting, and observe how she thinks over each stitch. She cannot talk, she is too busy, and yet she knits very slowly; but by degrees, as the connections begin to be made between her cells, and fresh paths trodden across the "common" of her brain, the work gets easier and easier, and at last her fingers go so fast you cannot see them, and yet she can talk all the time, and does not even require to think what she is doing.

Three Actions of the Brain. The actions therefore of the brain are three in number:

1. VOLUNTARY AND CONSCIOUS, always proceeding from the cortex, which may be merely abstract action of the thought centres or the purposive physical replies to sensations of light, sound, or common feeling.

2. ACQUIRED OR ARTIFICIAL REFLEX acts which are mostly unconscious and connected with the mid-brain, and largely consist of actions purely voluntary which by continual repetition have passed out of consciousness, and are no longer sent up to the cortex [see diagram 124], but are short circuited in the mid-brain.

3. NATURAL REFLEX actions entering outside conciousness, and connected with vital physical processes, and mainly centred in the lower brain, or medulla, and the spinal cord.

THINKING & CONCENTRATION

Memory and Attention. Linking up Memory with Consciousness. Training the Memory. The Necessity for Selection and Concentration

By HAROLD BEGBIE

ONE of the profoundest mysteries of human personality is the faculty which we call memory. This faculty has been defined as "the mental capacity of retaining unconscious traces of conscious impressions or states, and of calling these traces to consciousness with the attendant perception that they (or their objects) have a certain relation to the past." Locke defines memory, in "Human Understanding," as "the power to revive in our minds those ideas which, after imprinting, have disappeared, or have been, as it were, laid out of sight."

The phrase "laid out of sight" forces on the studious mind the mystery of memory. There is a department of our mental machinery which retains images, ideas, and impressions. It is a department of our mental machinery which is not included in that more obvious department which we call normal consciousness. Our normal consciousness does not keep a perpetual memory of all its impressions. Challenged to repeat or to relate one of these impressions, normal consciousness has to apply to another department of the mind for the necessary information. Separate altogether from normal consciousness, and yet (when properly trained) in sympathy with that normal consciousness, is the vast and almost unexplored department of human consciousness which keeps the tablets of experience.

Neglect of Early Training. Our business here is to show in what manner the sympathy existing between the normal and the secondary consciousness may be so strengthened as to keep the normal consciousness constantly informed with the knowledge of the secondary consciousness.

Some men are born with this strong sympathy, and are spoken of enviously as possessing wonderful memories. But in most cases of *bad* memory the effect may very frequently be traced, not to an imperfect physical organisation, but rather to neglect of training in childhood. It is certainly uncommon to come across a really well-trained and efficient man who is not gifted with a smooth-working and precise memory.

There are many men who profess to educate people's memories. They have some mental gymnastic or some particular dodge by which they affirm that it is possible for anybody to remember anything. These gymnastics and dodges have rightly been denounced by Fitch as "mere processes and a sterile mnemonic." No mnemonic words and no mnemonic lines can ever permanently strengthen that extreme sympathy between the two orders of consciousness without which no man can possess a really efficient memory. How, then, can they be strengthened? How is it possible for a person who finds difficulty in remembering names and dates, people and scenes, books and impressions, to link up his consciousness with his memory so as to be able to recall any of these impressions and experiences at the immediate desire of his will?

Training the Memory. We believe there is only one sound method of "training the memory," and that is by systematic use of information acquired and impressions received. The "things laid out of sight," that is to say, must every now and then be looked over. As a good housekeeper looks over her store cupboard or linen-chest, so every now and then must the student go over his store-house of impressions and ideas. He must continually be taking stock of himself, continually be making use of his knowledge.

A person with a bad memory (which means a person whose lines of mental communication are weak) is very often far more impressed by a particular thing than one whose memory is good. A person with a bad memory may be far more moved by "Lear" or "Hamlet" than a person with a good memory; but the person with a good memory, after reading these plays, is able to quote certain lines and to tell the movement of each drama in the precise sequence of the poet, while he of the bad memory will jumble the lines of one play with the lines of the other, mix up the movement of one play with the movement of the other, and find it impossible to give any precise account of the two dramas.

And yet the secondary consciousness of the man with the bad memory probably retains a far sharper image and a far more delicate appreciation of the dramas than does the secondary consciousness of the man who can so glibly recite his impressions, and with such admirable ease. The problem, then, for the man with the bad memory is how to establish better communication between his normal and secondary consciousness. He must be careful to remember that his memory retains an absolute impression of the drama, and that it is only his capacity to call up those impressions which is so seriously at fault.

The Uselessness of Memorising. To learn any portion of these plays by heart is not a good practice. Verbal memory is not real memory. The remembering of words and lines is an act, it is not a continual correspondence between normal and secondary consciousness. Far better than "memorising" words and lines, as it is called, is the habit of *thinking over* a scene. It is a curious fact that people with bad memories are nearly always impatient thinkers.

Like a hot-headed soldier, they rush through the country of new experiences without troubling to establish lines of communication with their base. This means intellectual destruction. Every step taken in knowledge must go with a strengthening of the lines of communication. And the lines of communication are Thought.

Reading and Thinking. We believe that a child's memory can be trained by making it discuss what it has lately read or seen, making it think. By this we do not mean that parrot-habit of question and answer between teacher and pupil, but rather an intellectual talk in which the teacher skilfully induces the pupil to speak about what it has lately been considering. In like manner the adult student may cultivate a good memory by immediately going over in his own mind some chapter in a book, or some scene in a play, which he has just read. He will have to check in himself the feverish desire to race through the book—curiously enough, paradoxical though it may seem, the chief passion frequently of people with extraordinarily strong memories, and therefore weak lines of communication.

A mind that receives sharp images is always eager to receive more, and goes rushing on without pausing to see that the lines upon which these images travel from the secondary to the normal consciousness are established. It is the person whose mind does not receive sharp images who reads ploddingly, and carefully impresses on himself the need of remembering what he reads.

Impatience, then, is the first obstacle to be got out of the way. Slow reading, frequent pauses for reflection, and regular intervals for going over in the mind the images received are the best means of establishing our mental lines of communication. The student will also find it useful to discuss as frequently as possible the matter with which he has engaged himself. Conversation is the examiner of our minds. Another useful exercise is the writing down of impressions, and this is one which should regularly be employed. In writing the brain is quieter, for the eye is undistracted, and it is only in such a condition that lines of communication can be established. As the exercise is more and more employed it will be found that more and more impressions return to the normal consciousness.

The Necessity for Selection. It is a helpful habit after witnessing a scene to close the eyes and strive to see it once again with the mind's eye. After this a verbal description may be given to a friend; and after that a written description should be made of the same scene—each exercise bringing out increasingly the details and the colour and the movement of the whole impression.

The act of forgetting is a great help to the act of remembering. Here the necessity for selection comes in. It is a fatal practice to load the mind with the burden of unessentials. It is a most useful practice, strengthing both the memory and the balance of the mind, to select consciously essential things for remembrance, and to discard consciously everything else. Any laboured effort to "memorise" in a wholesale fashion is to be reprehended; its result can only be a confused and chaotic storehouse of information out of which can flow no ordered and definite impressions to the normal consciousness. Intense interest in a subject, together with observation and criticism, will build up a discreet memory, and keep open the lines of communication. In other words, *thinking about a thing* establishes between the normal consciousness and the secondary consciousness a certain and an absolute sympathy concerning it.

Does Memory Know all Things? We cannot leave out from this article, although the subjects are treated in their proper place elsewhere [see PSYCHOLOGY and PHYSIOLOGY], the psychical and physiological sides of memory. There is the definite act of recalling an impression, and there is the "subliminal uprush" which presents to consciousness some experience on our part of which we had entirely forgotten the knowledge. Everybody is aware of these marvellous pictures which suddenly glow before the eye of consciousness and make the far past, for a single instant of time, as vivid as the present. Men have related that in moments of great danger—such as drowning—their whole past life has flashed before them, and it is a common experience of anæsthesia to relive in the few moments of the anæsthetic's power over our consciousness long years of our life, with every incident as vivid and as detailed as it was in the past.

By these experiences we are able to perceive that the memory of man is perfect. Every picture is photographed indelibly, every sensation is recorded infallibly. Nothing can happen to us—no great emotion or passing and elusive sensation—which is not faithfully treasured in the memory. And if, as certain men of science declare, the memory inheres "in a single cell, or neuron, or even in a single living molecule," we may feel disposed to answer that there must then be in us a perfect memory of not ourselves alone, but also of the lives of our fathers and our forefathers to the creation of the world, since that single cell or neuron has descended unto us from the first and parent cell of conscious existence.

Thinking about Things. But we find difficulty in remembering early events in our life. No man can go back to the memory of his own cradle. Few men can remember the first word they spelled or the first sensation they consciously received. The memory in each one of us—descended from endless ancestors—may, or may not, retain the impressions of our infancy and the memory of creation's past; but, at least, we know that we ourselves have no power over that memory, cannot exercise any dominion over it, concerning any of the impressions it recorded before we ourselves became definitely aware of conscious thought. From this we see that thought is the great rivulet which flows from the spring of memory to the tap of consciousness. Thought draws the water from the well, and brings out of the hidden places of our being the refreshment which we call memory. By thinking about things (not by learning things by heart) we cultivate increasing sympathy between the secondary consciousness and the normal consciousness. The dazzling uprushings of genius, concerning which Frederic Myers has written with such amazing lucidity, belong to the subject of Memory, but cannot be explained. It is permissible to think, however, that these subliminal activities are the result of thought in the past—not necessarily thought of the particular thing, but the habit of thought which has so perfectly placed in sympathy the memory and the normal consciousness that impressions travel easily and continually from the one to the other.

We believe, then, that just as the habit of thought creates the ordinary good memory of the average efficient and capable man, so that same habit carried to perfection creates that wonder and mystery of the world, a genius. The whole secret of the application of our education, and the use of our experience, lies in the creation of entire sympathy between the memory and the normal consciousness, and this sympathy can only be established by perpetual thought and regular self-examination. Let it, therefore, be seen that the matter is not one of training the memory (the memory, in all probability, being a more or less perfect record of our experience), but rather one of establishing between the memory and the normal consciousness, which calls itself "I," a channel of communication and an intensity of sympathy. To do this we must cultivate the habit of continual thought.

Concentration. It has been said that even the most earnest and pious person cannot say the Lord's Prayer without a wandering thought. The reason is simple enough. The mind is influenced by the association of ideas. A word, a phrase, a movement, a scent, is sufficient cause to set the thought of a mind following that particular thread through the labyrinth of its memory. To concentrate the thought upon a single thing, without following any of the by-paths suggested at every movement along that one and definite road, is an exercise of will requiring the greatest strength and the most sustained effort.

And yet this concentration of the mind is one of the essentials in an application of education to the affairs of life. No man can hope to puzzle out a problem, to invent a new thing, to improve upon existing things, or to reveal any new aspect of truth, unless he has it in his power to concentrate his whole mind upon the matter in issue.

Can he, then, learn to acquire this definite and decisive control over the machinery of the mind? It is possible, we believe, to teach children the habit of concentration, but in the case of an adult conscious of no particular interest in life the process is one of great and almost overwhelming difficulty. Unless, indeed, the desire to acquire concentration is sincere, every effort will be in vain; and both in the case of the child and of the adult there must be interest in the subject on which concentration is desired. Given, first, an eager desire to acquire absolute control over the machinery of the mind, and secondly, the opportunity of practising on some favourite subject, there is no reason why an adult should not learn, at least in some degree, this "one pre-eminent habit of education."

The Old Way and the New. According to Mr. Francis W. Parker, Principal of the Chicago Normal School, who has written exhaustively on this subject, the education habit of attention, or as we put it, concentration, "is purely a cultivatable one."

"In simple spontaneity," he says, "without direction, there is very little development of the habit of attention. There may be many acts of attention, but they cease before they reach the education point, or they have no organic relation each to the others. The cultivation of the habit of attention is the main factor in education; the habit of observing closely, listening intently to language, and of reading intensely, are the fundamental means by which self-activity is induced and developed."

The Americans have developed, or perhaps we should say are developing, a system for cultivating the habit of attention. Like everything else which comes from America it is not new, but is rather a swift and revivifying development of something old. In the present instance, the American method is an improvement on an Asiatic method which has been in use among the Buddhists for countless centuries. The Buddhist gives a pupil a stone, bids him hold it in his hands, and cautioning him against lifting up his eyes from the object, instructs him to fix his thought to the stone and to hold it there with the tightening force of his will.

The American, on the other hand, gives his pupil an orange, and bids him look well upon it. After that the pupil is allowed to model the orange, then to paint it, then to draw it, and then to study it. As soon as the shape, the colour, and the character of the orange has been mastered, it is peeled, and the skin is observed with minuteness. Then it is cut into parts, each part is examined, and then the pulp and seed are observed, drawn, painted, and descriptions given of them in writing.

The Secret of the New Way. The difference in these methods will be appreciated at once. In India the fakir may be seen who has clenched his hands until the nails have grown through the palms and thrust themselves through the backs. In America the man may be seen who has learned to make an eternal record of the human voice and who has harnessed electricity to the service of mankind.

The secret of the American success in this method lies in the selection of the subject on which we seek to practice concentration. If you detest theology, it will not help you to concentrate your thoughts by listening to sermons. If you have no sympathy with music, the effort to concentrate your mind upon the logic of a music lecture will not help you one whit. If you are fond of flowers, do not try to concentrate your thoughts upon postage-stamps, and if you are fond of postage-stamps do not labour to concentrate your thoughts on electrical machinery. Whatsoever is your favourite subject, or the theme in which you fancy you have most interest, in that learn to acquire the educative habit of attention.

Self-examination. And yet there are many people who confess their inability to give their attention to anything, and who complain that it is impossible for them to acquire the habit of concentration, since any object dwelt upon for but a few minutes irritates the consciousness and arouses antagonism. For such as these, as we said at the outset, the path is beset with extremest difficulty. The great cities of the world are overcrowded with young people capable of not ten minutes' concentration. Whatever work they do, they do without delight, their thoughts wandering aimlessly through a chaos of mental impressions, the machinery of their mind running on without control of any kind—derelict intelligences. They experience in their lives neither exultation nor delight; they have no knowledge of real pleasure and real enthusiasm; the beauty and the splendour of the natural world, and the glories and the conquests of the intellectual world, have no significance for them. Beyond the ordinary pleasures of the physical organism, which we share with the animals, they know of no satisfaction.

In cases of this kind, the habit of attention can best be created by occasional exercises in intellectual egoism. The derelict intelligence, anxious to acquire the habit of concentration, and yet professing that it has no subject on which it cares to fix its attention, must begin with itself. Let such a man examine himself, dwell upon himself, analyse and dissect himself. Let him begin by learning to observe himself. Why does he do such a thing? Why does he permit himself such a habit? Why does he go to such a place? By repeated questions of this kind addressed to himself, he may arouse out of its suffocating torpor the will which has ceased to direct his volitions. At every turn of his day he must learn to be observing himself by means of questions. Haply, in the end, this morbid self-examination may lead to such disgust with himself that his consciousness, taking upon itself new strength, will fling off the mental torpor which has obscured his intelligence like fumes of wine, and take possession of the machinery of his mind, controlling it and guiding it to conscious ends.

The habits of reading intently, of conversing intently, of listening to spoken words intently, help to build up the properties of concentration.

Do it With Thy Might. We should do all things with conscious direction. The negation of concentration is slackness. To read slackly, to talk slackly, to listen and to observe slackly, is to loosen all the muscles and fibres of intellectual alertness. The student must for ever check in himself any slackening of interest. If he is reading, and the subject begins to pall upon him, he must shut the book and turn to some other subject which will arouse his interest again. Whatever he finds to do, he must do it with all his might.

In exercises of contemplation, it is important that he first consider what he will observe in any particular object—its form, its colour, or its sound. His thoughts must all be regular; every fresh apprehension must arise from some definite act of attention. For instance, he must become aware of some particular curve in a butterfly's wing while fixing his attention on the form of the insect; he must become aware of a particular shade of green in the wing while fixing his attention on the colour of the insect. He must correct in himself the haphazard working of the mind, the spontaneous flight of his attention at every glance of his eyes. The mind must follow the orderly course of his system of observation, and must work always under his conscious control.

Wordsworth's "Wise Passiveness." While our object is to show here some of the chief and most useful methods of learning the art of concentration, and while we believe that this is indeed one of the pre-eminent habits of education, still we must attest our faith in the Wordsworthian theory of a "wise passiveness." There are certain natures of a highly intellectual order to whom concentration must always appear an irritating impertinence. And if to these people—generally people of some creative ability—ideas of a luminous kind come in their states of passiveness, streaming in upon them as sunlight streams into the morning, we may be sure that Nature does work in this direction, as well as in the more definite and decided fashion of directed energy. Therefore, it is good, even for the man who practises exercises of concentration, to permit himself certain minutes of passiveness, wherein he allows to flow freely into his soul the breath and secret influences of his surroundings.

Moreover, it is in moments of this kind that he will most easily gather the fruits of his concentration, for the mind gives nothing which has not first entered it, and the most glorious of "subliminal uprushings" must, we believe, have at least some part of its origin in our own observation and experience. If we are always acquiring, we shall never invent; if we are always observing, we shall never create.

However, the mind cannot be damaged, nor the play of the soul be hampered, by a continually increasing closeness of observation; and by this means, more than by any of the more elaborate exercises of professors on this head, however valuable they may be, the habit of the most useful concentration—the concentration leading to creative activity—may best be acquired.

NINETEENTH CENTURY PROSE

A Preliminary Sketch of the Period, together with a Study of Some of the Principal Essayists and Critics. "The Renascence of Wonder"

By J. A. HAMMERTON

NINETEENTH century prose, infinite in its complex variety of style, is distinguished by the common characteristic of critical inquiry: it aims at truth; it strives to touch the very heart of life. There are, as Goethe said, many echoes, but few voices. This is largely true of all literary periods; but the voices of the nineteenth century will compare advantageously with those of any preceding period. Where prose is concerned they are heard at their best, perhaps, in the novel. But the "new note" is hardly less resonant in the essay, the biography, the history, the book of theology, the narrative of travel, the scientific treatise, the studies of philosophy, art, education, politics, and economics.

If the twentieth century has opened for us with a wider and a nobler outlook on "the things that matter," it is due largely to the work accomplished in the preceding century in the domain of English letters, when our great writers took to heart the aphorism of an eighteenth-century poet. They saw with Pope, but with a finer insight than his, that "the proper study of mankind is man." The literature of knowledge and the literature of power belonging to this period are alike marked by the dominating but informed interrogative, for it was not only in imaginative writing that the last century witnessed what Mr. Watts-Dunton has called "the Renascence of Wonder," but in all fields of literature—in criticism and science, not less than in poetry and romance, this rebirth of "wonder" took place. The originator of the phrase thus explains it: "The Renascence of Wonder merely indicates that there are two great impulses governing man, and probably not man only, but the entire world of conscious life: the impulse of acceptance—the impulse to take unchallenged and for granted all the phenomena of the outer world as they are—and the impulse to confront these phenomena with eyes of inquiry and wonder."

"The Renascence of Wonder." Before studying the effects, let us glance at the causes of this change in the nation's literary life. The French Revolution shattered the scholastic formalism of English letters. Jean Jacques Rousseau stirred up a feeling for humanity such as England had never before acquired from French or Italian writers, much as she had been influenced previously by Continental models. The effects of the Red Terror threw the thoughtful back for a time into the slough of despond. We have seen how Wordsworth, for example, was bowed down in this way. Then a Scottish teacher read Mme. de Staël's "De l'Allemagne," set himself to master the German language, put Jean Paul Richter in the place of Jean Jacques Rousseau, and by the exercise, on the one hand, of the extraordinary knowledge he acquired of German philosophy and German individualism, and his painstaking elucidation of the Cromwellian epoch on the other, set aloft an ideal of manhood and patriotic duty which, faulty in many respects as the design may have been, influenced materially the popular view of history and the outlook on nature There were others who drank deeply at the Teutonic spring. Wordsworth was one of these, Coleridge was another, Byron a third; Scott and De Quincey were also of the company. Each was affected more or less differently, but at the same time profoundly. A new spirit was introduced into our literature—the spirit of wonder, which is of all human characteristics the most natural, the most fruitful in its influence not merely upon literature and the other arts, but upon every work of the hands of man. Had there been no "Renascence of Wonder," we had seen few, if any, of the marvellous inventions which rubricate the nineteenth in the calendar of the centuries. Thus it was that romance was reborn; that metaphysics acquired a new meaning; that humour was reincarnated. Men longed to look at things as they were; to see them "whole." Carlyle entered as an iconoclast into the temple of "the Gigmanities"; and of all the masterminds of the century, he is the one who, both directly and indirectly, has stirred most deeply the heart of the vast reading public called into being by the mechanical inventions of what Dr. Russel Wallace has called "the Wonderful Century."

Literature and Politics. The history of the essay, both critical and constructive, in the century we are considering, is bound up with the history of the periodical.

Something of the same kind may be said of both poetry and the novel. The various periodicals having a political bias, if not basis, literature developed more or less under the ægis of politics. The writers made the reviews and the reviews helped to make the writers. If the student, happily versed in more modern literature, approaches some of these old masterpieces in a spirit of wonderment at the fame attached to them, he must try to forget his later knowledge. He must look at the work with the eyes of the generation upon which it was sprung with such magnetic effect. Herein lies the value of the historical and comparative method in the study of all literature. To-day much of the vital force which animated the work of earlier writers has been scattered, much of their "thunder" has been stolen, the knowledge in the light of which they wrote has been found to be misleading. But the saving salt of an individual style preserves many an old and obsolete book from the blight of oblivion.

Styles of the Great Writers. Among the influences on later prose must be remembered the prose of the poets—the prefaces of Wordsworth, the miscellanies of Scott, the critical essays of Coleridge, the letters of Byron, Shelley, and Keats. But the student has a wonderful variety of object lessons in style before him, apart from these great names. There are the Puritan fervour and grim humour of Carlyle, the gentle intimacy of Charles Lamb, the graceful confidences of Leigh Hunt, the aerial cadence of De Quincey, the emphatic, unmistakable vigour of Cobbett, the brilliant antitheses of Macaulay, the incisive phrases of Hazlitt, the wit of Sydney Smith, the beautiful imagery of Ruskin, the flowing sea-music of Swinburne, the classic beauty of Landor's dialogues, the perfect serenity and harmony of Newman, the scholarly prose of Matthew Arnold, the undecorated diction of Hallam and Freeman, the picturesque pages of Froude, the jewelled sentences of Walter Pater, and the sparkle of Stevenson. In the main the prose writer who aspires to style must be an artist just as the poet is an artist, but the secret of style is, ultimately, the harmony between the subject and its treatment.

Literary Style. For general purposes style has been considerably influenced by the usage of journalism. The Press is responsible for a marked lessening of the distinction between written and spoken language. There must always be some distinction between the two. The skilled writer must of necessity possess a close acquaintance with the meaning of words; and it is, perhaps, a defective knowledge of the meaning of words which lies at the root of most failures in composition. The speaker, by means of accent, emphasis, look, gesture, personality, can lend significance to a comparatively poor speech. The writer, if he would impress his readers as effectively as the speaker impresses his audience, must find literary equivalents for the methods and circumstances of platform and pulpit. But the aim of the writer who addresses himself to a wide public should be directed to the perfection of a style that shall be distinctive—a copied style is but a mask—clear and colloquial, yet avoiding baldness and vulgarity, and from which foreign words, once so plentiful in the "spotted Dick" period of English prose, shall be notably absent.

Biographers and Historians. While the [illegible] ave done much to increase our knowledge of bygone, and particularly of Elizabethan, literature, as well as to popularise various branches of scientific learning, the biographers have given to the prose of the period some of its greatest intellectual assets. Southey's "Nelson," Lockhart's "Scott," Carlyle's "Cromwell" and "Sterling," Lewes's "Goethe," Froude's "Carlyle," Masson's "Milton," Spedding's "Bacon," Stanley's "Arnold," are classics that for one reason or another are never likely to be superseded. The influence of English historical methods has been world-wide. The nineteenth century historians are worthy successors of Gibbon. They have determined the unity of history, brought the study of evolution and environment to a pitch of scientific accuracy, and made history a fascinating study.

Theology and science, philosophy, politics, economics, art, education, and travel will be briefly touched upon in our chronological study of the leading prose writers of the period. There remain, however, before we take up this chronological study, two facts of especial interest that must be noted. One is the high literary value of much of the scientific literature of the time, as disclosed, for example, in the writings of Huxley; the other is the distinction attained by women writers. The latter is a portent that should commend itself to some philosopher of the future; its ultimate significance is hidden from our ken.

Essayists and Critics. No serious student of English criticism can afford to neglect the prose writings of SAMUEL TAYLOR COLERIDGE (b. 1772; d. 1834). They are by no means easy to read at the outset, but when the author's point of view has been attained they will prove most stimulating and suggestive. The "Lectures and Notes on Shakespeare" are especially valuable both on account of their great intrinsic value and the effects they had on later estimates of the national poet.

SYDNEY SMITH (b. 1771; d. 1845), FRANCIS LORD JEFFREY (b. 1773; d. 1850), and HENRY PETER LORD BROUGHAM (b. 1778; d. 1868), were jointly responsible for the early numbers of the "Edinburgh Review." They were politicians first and men of letters in a secondary sense. Sydney Smith's was a natural wit, but it was always under the control of good taste. His style was natural, and he used with unequalled effect against the forces of pretence and pomposity the process of logical inquiry known as the *reductio ad absurdum*. Jeffrey was master of a style the importance of which is derived from the fact that it served as a model to his greatest contributor, Macaulay. Brougham's zeal for popular education was greater than his discretion as a critic. WILLIAM GIFFORD (b. 1756; d. 1826), the first editor of the "Quarterly Review," was another "man with a bludgeon," whose best services were those he rendered to the Elizabethan dramatists and especially to the memory of Ben Jonson. Few men whose names are remembered in literature ever wrote more that has been forgotten than did ROBERT SOUTHEY (b. 1774; d. 1843). His fertility of production was as amazing as its variety. He was a scholar, and, considered as a stylist alone, claims a high place among his contemporaries. And yet "of what is called style," he said, "not a thought enters my head at any time. I only endeavour to write plain English and put my thoughts in language which every one can understand."

SIR WALTER SCOTT (b. 1771; d. 1832) wrote almost as incessantly and as variously as Southey, but with much greater success, independently of his greatest work. His essays on chivalry, romance, and the drama, and his letters on demonology and witchcraft are still eminently readable; and he was a painstaking as well as a capable editor, especially of Swift. JOHN WILSON (b. 1785; d. 1854), the "Christopher North" of "Blackwood's Magazine," is chiefly remembered as the literary parent of De Quincey, as part author of that brilliant series of dialogues, "Noctes Ambrosianæ," and author of a work entitled "Lights and Shadows of Scottish Life." JOHN GIBSON LOCKHART (b. 1794; d. 1854), Scott's son-in-law, and Wilson's friend and colleague on "Blackwood," who succeeded Gifford as editor of the "Quarterly," gave to journalism much that by right should have been devoted to literature. His masterpiece is the "Life" of Scott, second only to Boswell's "Johnson" as a model biography. Every student must read it, but may neglect his novels, though "Adam Blair" is worth reading if one should come across it.

Charles Lamb. One of the greatest, as he is one of the least pretentious, of English prose writers, is CHARLES LAMB (b. 1775; d. 1834); but the now world-famous "Essays of Elia" originally issued from the press, at all events in their collected form, upon a cold and irresponsive world. In the history of English prose Lamb stands as much alone as Landor or Sir Thomas Browne. He is master, not of one style, but of as many styles as he possessed moods. He is full of elusive echoes of the old writers whom he loved. His is the art that conceals art, for seemingly he is as frank and as communicative as Montaigne. His character is written in his "Essays"; his autobiography in his Letters. He wrote for magazines—the "London" in particular—but he wrote what he would, and not merely or principally for the pecuniary proceeds of literary work. Herein, undoubtedly, lies part of the secret of his enduring charm. Then, he was a man of many friends. His life-story is as inspiring as that of Scott. Posterity reverences Lamb almost as a memory of a golden age, as the embodiment of a quality of heart from which it has parted; it looks on him as Lucifer looked on Paradise lost. But Lamb was not only an essayist of unique charm; he was also a critic of rare insight and surprising accuracy. Nothing that he wrote, and wonderfully little that his life inspired others to write of him, can the student afford to neglect.

William Hazlitt. In WILLIAM HAZLITT (b. 1778; d. 1830) we have a strong contrast to the man who regarded him as "one of the finest and widest spirits breathing." Hazlitt was indebted to Lamb, and acknowledged the indebtedness; but with a critical faculty as keen as that of Lamb, he possessed not a scintilla of "Elia's" human sympathy; hence, whereas the one is loved the other is given the meed of almost frigid praise. Yet Hazlitt's is a name of first importance. "We are mighty fine fellows," said Stevenson, "but we can't write like William Hazlitt." He is the master of the apt and illuminating phrase. The student of Shakespeare owes much to Coleridge's "Lectures," he owes much also to Lamb's "Critical Essays," but he must also study, and study with attention, Hazlitt's "Characters of Shakespeare's Plays"—a work dedicated to Lamb—and the "Lectures on the Dramatic Literature of the Reign of Elizabeth." Of equal note are the "Lectures on the English Comic Writers" and "Lectures on the English Poets." It must be confessed, however, that there is more venom than justice in the personal sketches he called "The Spirit of the Age." But, as a recent writer in the "Quarterly Review" well says, noting the haunting motto prefixed to the delightful essay "On Sundials," "if one only counts Hazlitt's serene hours, they prove him to have had something far higher than the talent which does what it *can*. He had his share—no one who has tasted the fruit of those serene hours can gainsay it—of the genius that does what it *must*."

Thomas De Quincey. An object of the most contradictory criticisms is THOMAS DE QUINCEY (b. 1785; d. 1859). Sir Henry Craik, in his introduction to the final volume of "English Prose Selections" describes De Quincey's prose as spurious, and as possessing "all the appearances of eloquence except those that are true." Further on in the same work Mr. R. Brimley Johnson, who alludes to De Quincey's "vigorous intellectuality," "genius," "richness of fancy," and "splendour of style," says: "Exactness, carried to the verge of pedantry, is the conspicuous merit of his style, which is further strengthened by a scrupulous attention to the conditions of effective comparison, and by the explicitness with which his statements and clauses are connected." With Hazlitt and Lamb, De Quincey was a contributor to the "London Magazine," in which his "Confessions of an English Opium Eater" appeared. De Quincey stands sponsor to the modern school of "prose poets" of which Mr. Swinburne is the great exemplar. He has much to attract, but is dangerous to follow. He lacks a certain dignity, is normally without what we understand by the word "reverence," and he is at times terribly discursive; but we must remember that the bulk of his work, which has been collected in nine volumes, was anonymous journalism, and that the writer kept up a weak physique by the use of opium. The "Confessions," the historical essays, "Levana; or, Our Ladies of Sorrow," and the "Autobiographic Sketches," should be closely studied. De Quincey has been styled the "Boswell of Essayism," so intimate are his revelations of both himself and his associates. He possessed to an almost amazing degree an instinct for dramatic expression. Whatever some of whom he wrote may have thought of his character drawing, he was well liked personally, and in his later years he proved a good husband and a devoted father. Perhaps Mr. Birrell is right when he declares that De Quincey will always be "above criticism." This great essayist was a rhapsodist, but he was, too, an inquirer, and his influence was against cast-iron formality in English prose.

VIOLIN PRACTICE

Intonation. Major, Minor, and Chromatic Scales. Time Table for Practice. How to Clean the Instrument. Intervals

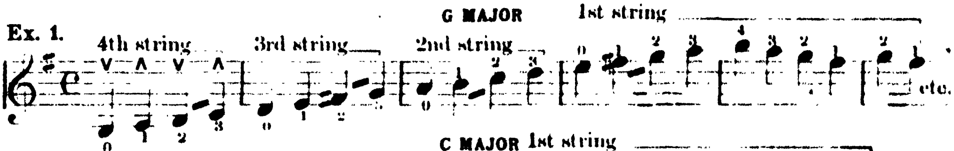
VIOLIN
continued from page 2195

By ALGERNON ROSE

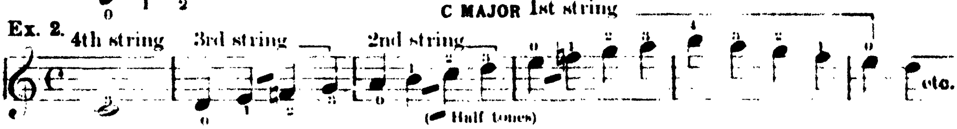
REFER to the keyboard of a piano if there is any doubt about getting the right notes. Of equal importance with the time-sense for the violinist is the necessity to play in tune. Accurate intonation in fiddle playing must be cultivated assiduously. Gradually the ear will become accustomed to the correct intervals, and identify them without the aid of a piano. If it does not, the student had better learn a keyboard instrument, on which the intonation of the notes is furnished mechanically.

Slowly and firmly try the scale of G major. Begin on the fourth string with a down-bow and sound the open note, G. If a bar usually begins with a down stroke because of the pressure being stronger, it finishes, as a rule, with an up-bow, the last beat being less accentuated than the first. Put down the first finger near the head so as to stop the A above the G. Play this with an up-bow. Place the second finger on the string to sound B. Bring the bow down resolutely. To get the semitone above for the note C, put down the third finger close to the second. Play with an up-bow. The neighbouring open string supplies the next note, D. Having bowed this, put the first finger on the third, or D, string to get E. The second finger will produce F♯, and the third, close to the second, the G♯ above. Never raise a finger already down, unless for the production of a lower note on the same string, or a note on another string. The second string gives the open A, the first finger on it the B, the second C close above, and the third D. Lastly, the first string furnishes the open E, the first finger F♯, and the second, close to the first G♯. Go down the scale in the same way. Count with each sweep of the bow [Exs. 1 and 2].

Ex. 1.

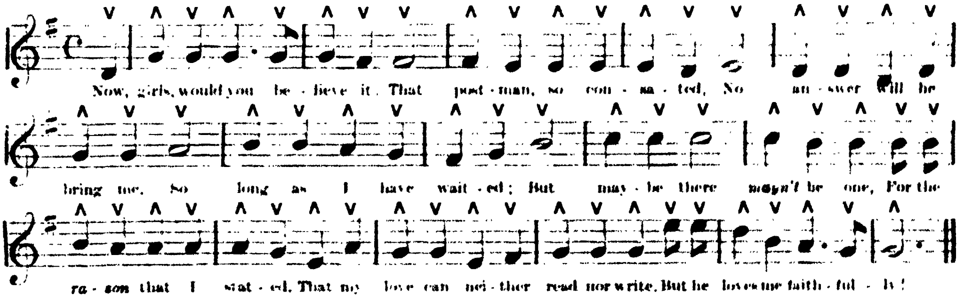


Ex. 2.



Music and Numbers. To become an accomplished violinist, the fingers of the player must learn, by diligent practice, to associate tones and numbers automatically. In this sense, fiddle music and mathematics are twin brothers. When the Greek philosopher, Pythagoras, based his series of sound ratios on numbers, he anticipated Corelli, the father of violin players, by twenty centuries. The easiest way of committing to memory the numerical fingering of G major, or any other scale, is to vary the order of the notes. Thus, if we take a simple melody of moderate compass in that key, we find at once a suitable exercise. For this purpose, the student should now try to play the refrain known as "Katie's Letter," to which we attach the words, so that the notes may be bowed with suitable expression [Ex. 3].

Ex. 3.



Now, girls, would you be - lieve it, That post - man, so con - sa - ted, No an - swer will be
bring me, So long as I have wait - ed; But may - be there mayn't be one, For the
ra - son that I stat - ed, That my love can nei - ther read nor write, But he loves me faith - ful - ly!

In A minor, instead of the semitones occurring between the third and fourth and seventh and eighth notes, as in the major scale, they now come between the second and third and seventh and eighth notes. The effect of this change gives a more plaintive character to the minor than the major modes.

The beginner will now note that, although the semitones are not the same in ascending as in descending a minor scale, the fingering is alike both up and down, the production of the right notes depending on the stopping being "humoured" by the fingers. Below C (the major scale which has no sharps in music) at an interval of a minor third comes the note A. [Exs. 4–8.]

The pupil should now get pen and music paper. To impress on the mind the position of the semitones, it is well to copy out the scales; first, the tonic majors and relative minors, and then the tonic majors and tonic minors, the latter being those minor scales which begin on the same note but have a different signature of accidentals. Having written out the scales in all the sharp and flat major keys, confining the range to the compass of one octave, practise them carefully. To get variety, write the first and third scales in four-four time, the second and fourth in three-four rhythm, and so on.

A MINOR

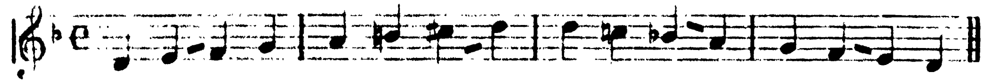
(Observe altered situation of the half tone in third bar in Harmonic form)

Ex. 8. The MELODIC form of the same scale



(☛ Half tones)

Hymns. In order to impress the correct fingering on the memory, take the top line of some well-known hymn and transpose it into the different keys. Practise it slowly, and try to convey the meaning of the words to the sounds. As correct intonation is of great importance, the student should accustom himself to recognise, before beginning a piece of printed music, the key in which it is written. The "key" to the key is indicated by the last note of an unaccompanied melody, or the bottom bass note of the accompaniment. This is the general rule.

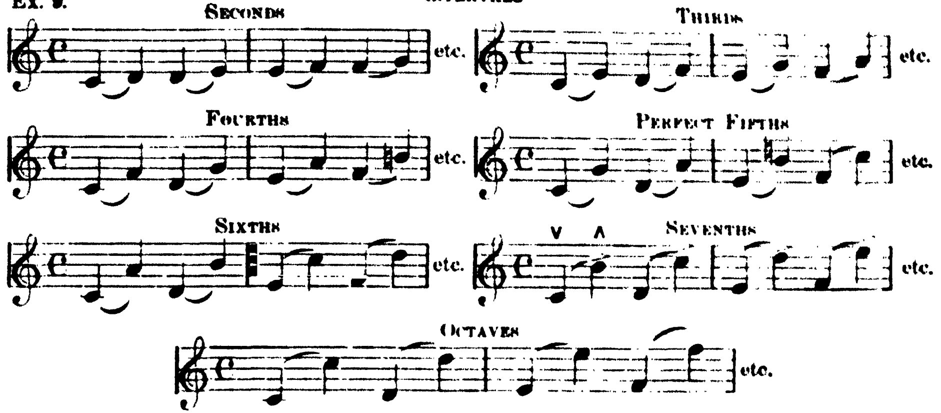
Scales. Many beginners have an unfortunate prejudice against practising scales. Although a badly played scale is decidedly uninteresting to listen to, yet under the bow of a Sarasate or an Ysaye there is nothing more brilliant and beautiful. It is the thoughtless way in which scales are practised that makes them so distasteful. Think, therefore, of a great master playing a scale in an ideal manner. Try to imitate the dignity of his tone in bowing slowly. When, in course of time, the scale can be taken more quickly, the student should always have in imagination, if he wishes to improve his execution, the charm of the rush of brilliant sounds obtained by a clever virtuoso. The beginner's first attempts to play scales may be unhappy, but disappointment is the companion of all true happiness. The latter will come presently and be doubly appreciated if the pupil perseveres. Later on the scales may be extended to two or three octaves. "One thing at a time" should be the maxim of the beginner. If he succeeds in reading and fingering the notes of the different scales within the compass of an octave well in tune, slowly, he will have done admirably. Should the playing of scales become irksome, he has himself to blame for not concentrating his mind on their study.

Difficulties. It is attention to the things which are tiresome to the majority of people which makes for success, and even, in some cases, for genius. In this complex life of ours, the mind, if it be a good one, is strengthened by the difficulties it encounters. In the same way, scale playing strengthens the fingers. There is consequently considerable moral discipline in practising scales not once a fortnight, but regularly every day. The secret of success in singing, it may be whispered, lies in the ability of the vocalist to "scale" the voice beautifully. Of all instruments, the violin approaches most closely, in its methods of intonation, to the human voice. The practice of scales, therefore, is essential for proficiency.

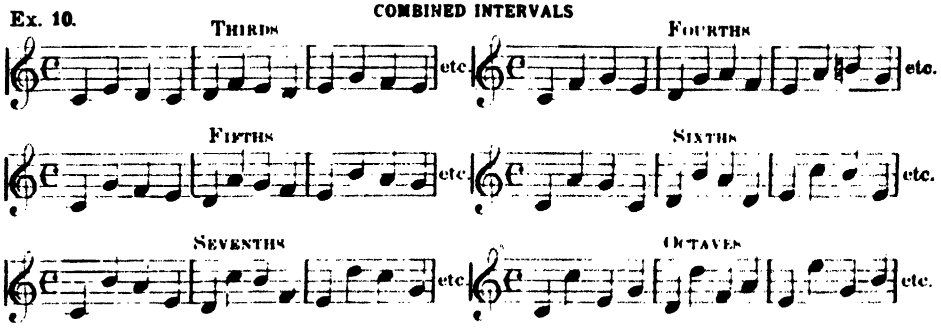
If scale playing has been varied by the slow practice of chants, as suggested, the student will already have begun to make acquaintance with most of the *Intervals* [Ex. 9].

Begin each exercise slowly. Work up the speed gradually. Play each pair of notes with a full bow, down on the beginning of the bar, up on the second beat, and so on. Other methods of bowing will be dealt with later. Having studied the course on Transposition [page 1057], transpose the foregoing exercises into different keys. Next combine the intervals in the way suggested in Ex. 10.

Ex. 9. INTERVALS

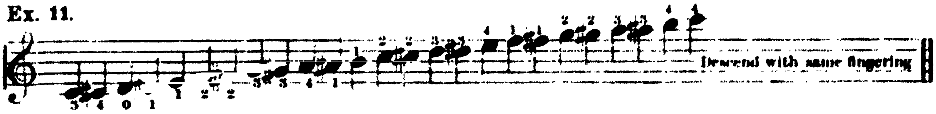


Ex. 10. COMBINED INTERVALS



Many sharps or flats may look formidable on paper, but the fingers of the violinist are not confronted, like those of the pianist, with black keys at a higher level than are the ivory notes. Therefore, accidentals should be easy to play on the violin, although Berlioz, in his clever "Instrumentation," gravely writes that the scales of E♭ and F are "difficult," that D♭ is "very difficult," and D♯ "almost impracticable." But Berlioz was a flageolet player rather than a fiddler, and Spohr, one of the greatest of violinists, carries more weight when he says that the violinist has an "equal command of all keys, even those the most remote."

Ex. 11.



The Chromatic Scale. This question of accidentals leads us to the artificial scale, known as the *Chromatic*, which proceeds entirely by half-tones [Ex. 11].

The student should remember that more than one note in this scale must never be stopped with the little finger, and that the same finger must never be employed thrice in succession. He should avoid also sounding the open E and A strings, whether in ascending or descending. The exact fingering depends a good deal on the character of the music. In moving the second or first finger up or down, be careful to go at once for the precise stopping-place. Lingering midway in the stopping spoils the intonation.

Let us repeat that, if proficiency is to be attained, the student must concentrate his attention on one exercise at a time. As soon as the slightest facility in playing has been arrived at, a desire arises to skip serious study and get on to "pieces." With a pupil who has a master to check him this tendency is bad; but the temptation requires double will-power to conquer when the pupil is working unaided. Instead of frittering away valuable leisure with meaningless tunes, the ambitious student will be better employed acquiring facility in steadily bowing the *Broken Chords* in Ex 12.

Practise these slowly at first. After getting the intervals in tune, increase the speed. Transpose this exercise into all the other major keys.

Practice Table. At this stage the student should make out a practice table. Apportion the time which can be devoted daily to violin study somewhat as follows:

Scale of C major..	5 minutes
„ „ A minor	5 „
Intervals	15 „
Broken chords	15 „
	—
	40 minutes

This plan can be changed discreetly day by day, but 40 minutes at first is long enough for the beginner who is in earnest. It is wise to practise in solitude. If the room cannot be otherwise reserved, rise an hour earlier than usual. In that case, to avoid annoying sleepers, a skeleton, or mute violin, can be bought for about 10s. But these so-called practice violins should be avoided wherever possible. They have a bad influence on the learner, and tend to destroy his conception of tone. A "mute" is better, and can be purchased for a few pence. Placed upon the bridge, it diminishes the sound of the violin. In any case, the beginner desirous of cultivating a good tone should refrain from playing feebly at first. Not only should the bow, both up and down, be made to bite well without roughness throughout its length, but the fingers must stop the strings firmly. This effort may produce corns on the tips of the fingers of the left hand, but in a short time these will give no trouble.

End of Practice. After practice, slacken the hair of the bow. Before putting the violin away, rub off the rosin with a soft handkerchief, and wipe the stick of the bow. Should the fiddle require general cleaning, wipe it with weak whisky and warm water, and finally with a little light oil. When the bow gets greasy, wash it with soap and tepid water. Conclude the bath with fresh and cold water. Dry the hair before a fire, then rub with fine powdered rosin.

As soon as the many difficulties which confront him begin to be perceived, the first eagerness of the violin student is apt to abate. It is easy then to neglect practice for a while. But such a procedure is fatal to progress, and it is only by resolutely adhering to the plan of study drawn up that the self-instructor will presently become a good player. The beginner must imitate the tortoise rather than the hare if he wishes to triumph.

The Function and Structure of our Ears. Their Amazing Power of Reconstructing Sounds. Analysis of Sound, and Some Experiments

By Dr. C. W. SALEEBY

HAVING discussed the objective nature of sound, its speed, intensity, reflection, refraction and production, ending with its production by the oldest and most valuable of all instruments, which none of us needs to purchase, we may now turn to the consideration of the physical aspect of hearing. Let it be clearly understood that our business in this course is only with the physical aspect of a function which, of course, it is more properly the province of the physiologist to investigate. But we must carry the physical inquiry as far as possible, being quite certain of this, that the more complete it is, the more valuable will be the help that we are able to afford to the psychologist, who, after all, must build upon physics if he is to build securely. And by way of an introduction to the subject we may begin with a simple and easily dismissed question: How are we able to locate a source of sound?

The Direction of Sound. The use of the external ears in the lower animals is obvious to anyone who has observed them. It is evident that if these ears be inclined at different angles the animal will find a given sound louder when the ear is at one angle than when it is at another. He is thus immediately guided to the source of the sound. Even in man there persist three small muscles, attached to each of our external ears, the function of which—had they not lost it—is to move the ears in various directions. But, in point of fact, the large majority of people have completely lost the power of moving the ears at all, though some of them can move the ears in association with movements of the whole scalp, while a few retain the power in some small degree. But no one ever uses it for the purpose of estimating the direction of sound. In any case, the ear has so largely lost the shape which should make it valuable that the power would be of little value if we retained it. It has been shown that if the whole of the external ear be filled up with wax, leaving just a small hole corresponding in width to the canal that leads inwards to the middle ear, the acuteness of hearing is very slightly diminished—that is all.

Do our Ears Deceive us? Now, it may be argued that, in reality, we cannot judge the direction of sound, but are constantly deceived. The deception, however, is more apparent than real. We are deceived merely because the sound is reflected from some surface, and we locate the source of the sound in the direction of that surface. Nevertheless, our ears have served us quite faithfully in indicating the direction from which the sound immediately reached them.

The most careful experiments have been made, especially by Lord Rayleigh, in order to discover whether there is any factor whatever that determines our appreciation of the direction of sound except the one factor which we are about to discuss. It is found, however, that no other explanations of this power can be afforded.

Two Ears and Two Eyes. Our appreciation of the direction of sound entirely depends, then, on the fact that we have two ears. You hear a noise, and immediately turn to the left; the simple reason is that the sound is more loudly heard by the left ear—that is to say, by the right side of the brain—than by the right ear—that is to say, by the left side of the brain. Observe the curious fact that the hearing is really done most effectively, not in the part of the brain which is nearest the sound, but in the part which is furthest from it. The explanation obviously is that the brain appreciates not directly from the external world, but through the mediation of the organs of sense, and in the case we are considering it is the left ear that is most markedly stimulated. Various experiments—both those made for the purpose and the experiments of disease—go to prove that our internal comparison of the relative measure of stimulus received by the two ears is our means of determination.

The case is parallel to that of the eyes. In each instance the development of pairs of organs would appear to have been originally due to the same causes as have produced the double symmetrical arrangement elsewhere in the body. But whereas no extra value of any special kind is due to the fact that we have, for instance, one lung on each side of the body, the similar possession of two eyes means not merely that we are able to see things more intensely, but also that we are able to perceive their form in perspective by an unconscious comparison of the slightly differing images which the two eyes perceive; and, similarly, the possession of two ears enables us not merely to perceive sound more acutely, but also to perceive its direction. If a patient be completely deaf in one ear, he is compelled, of course, to use his whole head, just as a donkey uses its external ears, moving it as a whole until he chances to get the opening of the healthy ear opposite the source of sound, the position of which is thus identified.

A Simple Experiment. It is an obvious consequence that, if we produce sound in such a fashion that it is absolutely equidistant from the two ears, we shall be able to defeat any possibility of locating it, except in so far as the subject of the experiment is able to say that the sound *is* somewhere equidistant from the two ears. In order to obtain success with the following experiment, it is necessary that the acuteness of hearing in the two ears be equal. The subject is blindfolded, and a noise is made by the finger and thumb, or any other means, just in front of his nose, under his chin, or at the back of his neck. From the fact that the sound is heard equally in the two ears, the subject will rightly confine his guesses to the plane in which these places lie, but as to the exact part of the plane from which the sound proceeds he will be completely nonplussed. A sound produced under his chin is as likely to be referred to the top of his head or to the back of his neck as to its actual source. This simple experiment affords a very conclusive proof of the accepted theory. From this simple problem we must pass to the actual mechanism by which we appreciate sound. Thereafter it will be well to note other means by which sound can be appreciated or its consequences made evident.

The Structure of the Ear. The sound wave which has been more or less collected by reflection in the external ear passes through a short canal, at the bottom of which is found the *tympanum*, or *drum* of the ear, which is thrown into vibration synchronous with—that is to say, at the same rate as—the alternation of compressions and rarefactions that constitute the sound wave. To the inner side of the drum is attached a small bone which is joined to another, and it to a third. These three *auditory ossicles* (ossicle meaning a small bone) form a very oblique bridge across a narrow air-filled cavity which, though really little more than a slit, is known as the middle ear. The air which it contains is supplied from the throat by means of a special channel which is known as the Eustachian tube. This permits the air to pass in or out, so that its pressure may always be the same as that of the air on the outer side of the drum—that is to say, that its pressure may be the same as whatever happens to be the atmospheric pressure at any given moment. The persistence of this equality of pressure is necessary not only for comfort, but also for successful hearing. If we descend to the bottom of a coal-mine, where the atmospheric pressure is raised, or if we ascend in a balloon, so that the atmospheric pressure is lowered, it is a wise precaution occasionally to swallow one's saliva, as this act opens the Eustachian tube and permits of the equalisation of pressure. If the tube be closed, as may happen in disease, the air within the middle ear is apt to be absorbed and the pressure thus lowered, with evil consequences.

The Middle Ear. The business of the three bones is to transmit the to-and-fro vibrations into which the first is thrown in virtue of its contact with the tympanum. Two minute muscles are attached to these bones, one of which, when it contracts, tends to tighten the drum of the ear so that it responds more readily to aerial vibrations of small amplitude. The hearing is thus made more acute, and we therefore employ this muscle when we strain to hear. When the second muscle contracts it tends to lessen the rigidity of this threefold conducting apparatus. It is therefore of value when we try to reduce the intensity of loud sounds. Sometimes it is paralysed, and then loud sounds are found to be very painful. This muscle is the nearest approach that we possess, since we have no earlids, to an apparatus for cutting off external vibrations—which our eyelids do so efficiently for the eyes.

The Inner Ear. The third and last of the three bones is fixed to another membrane which is thrown into vibrations corresponding to the vibrations aroused in the tympanum, and which closes a remarkable canal filled with fluid, the said canal being part of the internal ear, the essential part of the organ of hearing. The sound vibration, more or less modified in amplitude, perhaps, by the action of one of the muscles we have named, is communicated to the fluid of this canal, which takes a spiral shape that has some resemblance to the shell of a snail, though it is very much smaller. This canal lies in the hardest bone in the body—the hardness and rigidity of which are of value, in that they do not tend to damp sound vibrations which are appreciated within it. As the sound wave travels along this spiral canal, it naturally affects an extraordinary structure which lies along the whole length of a continuous bridge or partition that divides the canal into two. This structure is known as the organ of Corti.

The Piano Theory of Helmholtz. Since the canal steadily diminishes in width throughout its entire length, it follows that the fibres constituting the bridge become shorter and shorter. This fact aroused the careful attention of the illustrious German physicist, Von Helmholtz, whose name will go down to all time as one of the founders of the doctrine of the conservation of energy. Helmholtz supposed that, as in the case of a piano, the shorter fibres of this bridge—those that lie nearer the apex of the spiral—correspond to musical notes of higher pitch, while the longer correspond to the low notes. This may be described as the theory of sympathetic vibration, or, more briefly, the resonance or piano theory of hearing. This theory has been widely held, but it is extremely difficult to perfect it in accordance with the facts. It is, however, most remarkable that there have been recorded numerous cases of partial deafness, where the patient was able to hear every note on the piano, perhaps, except one, or a sequence of two or three. In such cases it has sometimes been found that there has been some destruction of the structure of the internal ear, more or less corresponding to what might have been expected on the assumption that the piano theory of Helmholtz is correct.

The Function of the Cells. At any rate, the fibres of this long bridge are covered by a company of tiny living cells, which are provided with minute sensitive hairs, and which must be regarded as the true auditory cells, corresponding to the distinctive visual cells of the retina of the eye, which are the immediate means of our appreciation of those ethereal vibrations which we call *light*. The hairs of the auditory cells doubtless appreciate every motion or change of pressure which a sound wave from outside may impart to the fluid in which they are bathed. The base of each of these innumerable cells—the actual number being about 15,000—is directly supplied by a tiny branch of the nerve of hearing. But when we come to the transformation of material vibrations into nerve energy, we have reached the limit of what is ordinarily regarded as physical inquiry. The entire length of the canal we have described is about 1 in. As this is very much shorter than the shortest wave-lengths of any sound that we can appreciate, it follows that the whole internal ear must constitute one vibrating system, the whole of which at any one moment is in the same phase. The structure is infinitely more complicated than we have described, but perhaps the only one of its many details that need also be mentioned is the occurrence of a viscous substance which is always found at the base of the auditory cells, and which is supposed to have the function of preventing or damping after-vibrations.

How we Recognise Sounds. We may now turn to an aspect of our subject which would lead us, if we pursued it indefinitely, towards the subtle science of *æsthetics*, to which allusion was made when we began to study this subject. The question of the recognition of the pitch of a simple tone is difficult enough, as we have seen, but it is as nothing compared with the difficulties of understanding the means by which we recognise and appreciate compound tones—the means, for instance, by which the late Sir Charles Hallé was able, while conducting a full orchestra, to detect which violins were playing out of tune. Perhaps the best fashion of understanding the extraordinary difficulty of such a feat is to use the following analogy, which the present writer suggested some years ago.

Let us take the case of the movements of an electron constituting part of an atom of matter upon the surface of the moon. This electron is partaking of a very large number of motions—even begging the hitherto unanswered question whether it is in rotation on its own axis. We are sure, at any rate, that it is moving within the atom—probably revolving around the atomic centre. It also partakes in that movement of the atom as a whole which constitutes what we call heat. Together with the atom which it helps to compose, it must also be supposed to be drawn gradually towards the centre of the moon as she cools. It is also moving as the moon rotates upon her own axis, and as she revolves around the earth, and as the moon and the earth revolve around the sun. But astronomers tell us of the proper motion of the sun, and declare that the solar system as a whole is journeying at the rate of some 11 or 12 miles a second towards the bright star Vega in the constellation Lyra. Thus, there are seven or eight motions, and we know not how many more, which the electron is simultaneously performing. Upon these we may all be agreed, but at the same time we are also agreed that, at any given moment, the electron is moving in only one direction and at one speed. Its absolute motion is the consequence of the composition of all these relative motions

"Hearing by Imagination." Now, the case of the electron is extraordinarily similar to that of the particles of air in a complex sound wave. The mind forbids us to conceive that any of the particles are moving in two directions at the same time. In order to do so we should have to think of them in two places at the same time. What, indeed, reaches the ear when we listen, for instance, to combined orchestra and soloists, is not the sound wave corresponding to the voice of any of the singers nor the sound wave corresponding to any of the instruments. It is a wave of incredible complexity, the form of which is determined by all the sources of sound involved.

Each of these sources of sound can do no more than modify the form of the resultant wave in proportion to the form and amplitude of the wave which it would produce if, so to speak, it had the air to itself. In fact, then, when the ear of a musician distinctly hears the phrase which the violins are playing or the tenor is singing at any given moment, he hears what is not there; the wave form corresponding to the violins or to the voice is represented merely by one phase of the complex movement which the aërial gases are performing. The ear is thus able to reconstruct, imaginatively, the rest of the wave from a mere fragment of it, and the listener thinks he hears the tenor's voice, whereas in reality he only hears a complex sound wave, the form of which has been somewhat modified by the fact that the tenor has contributed his own tendency to it.

A Wonderful Power of Reconstruction. Similarly, in a clamour of voices, the result of which is one single wave form, the ear is able, at choice, to listen to the whole as a clang or harmony, or to recognise from all these voices one that is familiar, or even to recognise in that familiar voice the particular relation of over-tones which may indicate any particular emotion, such as joy or fear. Yet, unless we are to accept the inconceivable proposition that the atoms of air can be in two places at once, we are compelled to recognise that the ear has reconstructed, from a mere indication, particular wave forms which have no actual existence. In the opinion of the present writer, this analytical or reconstructive power of the ear is the most remarkable of all our sensory powers, and is seen to be none the less so when one examines the complex wave forms which the modern phonograph is able to record.

There is no analogy in the case of sight, which, indeed, is inferior to hearing in discrimination. Wherever one turns one's eyes, any given portion of the retina, or perceiving curtain, at the back of the eye merely appreciates the particular ether waves that happen to fall upon it. Even if one fixes attention on a particular part of the field of vision—a particular feature of the landscape or the freckle on the side of the nose of the person you are speaking to—there is no reconstructive or analytic power such as the ear possesses.

The Ear's Analysis of Wave Sounds. A complex wave form consists of a number of ripples of varying size and shape, moulded upon bigger wavelets, which, in their turn, are moulded upon waves bigger still. Each of the little ripples simply indicates all that is left of the wave produced by—say, at a choral-orchestral concert—a given horn or violin or contralto when that wave has been merged in and blended with all the other waves that are coming from the stage. Yet from a mere hint, such as an amputated curve in the whole complex vibration, the hearing ear can reconstruct and imagine that it hears the voice of any of the soloists or the tone of any of the instruments in the orchestra. The case is even more remarkable, indeed, than, for instance, the reconstruction of an extinct animal by study of one of its bones; for in the case we are considering there is really left not even an amputated portion of the sound wave belonging to any of the instruments or voices. It is impossible to point to any part of the wave form and say "the flute contributed that." If the diagram of the wave form of the flute were superposed upon the diagram of the complex wave form that is actually produced, there would be no coincidence between them at all. These considerations make this amazing power of the human ear more amazing still.

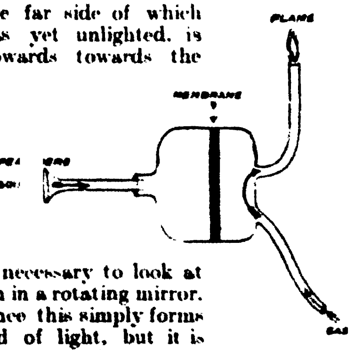
Sound can be Felt. If we realise that sound has an objective basis consisting of material vibrations, it will be plain that, as we noted above, there are other means than the living ear by which sounds may be appreciated. They can, of course, be appreciated by the finger—that is to say, the finger can feel the vibrations of a vibrating object. There is a profound difference between the impression which such an object makes on the sense of touch and that which it makes on the sense of hearing. But the objective fact, whether we call it sound or whatever we please to call it, is one and the same. Similarly, when a doctor asks the patient to say "ninety-nine," he may place his hand on the chest and feel the vibration, or may put his ear to the chest and hear it.

The phonograph offers a simple illustration of the means by which sound vibrations may be felt, so to speak, and recorded. Its essential part consists of a drum, which corresponds to the drum of the human ear and to which there is attached a needle; just as if one removed the tympanum and the little bone which is attached to it. The end of the needle makes marks upon tinfoil or wax which is made to pass underneath it. The shape of these marks and their depth correspond to the form of the sound wave which agitates the drum. If, now, the arrangement be reversed, the tinfoil or wax moves a needle placed upon it, affects the drum, and so reproduces exactly similar sound waves to those which made the original impression. It will be obvious to the reader that there is an analogy between the phonograph and the camera.

Professor Tyndall's Sound Flame. We have already, when discussing sympathetic vibration, made reference to the experiments of Helmholtz in the tuning of resonators, and it was noted that the resonators may be so arranged in a series as to affect flames placed opposite them. There is no real distinction between this action and the action of blowing at a flame and making it flutter. Many experiments have been made with flames especially designed so as to be very sensitive to sound, the most celebrated of these being the so-called vowel flame contrived by Professor Tyndall. This is about two feet high, and is extremely sensitive to all sorts of sounds and musical notes. It responds especially to tone of high pitch, and therefore to those particular vowels which contain the largest number of over-tones of high pitch. For instance, it is very much more markedly affected by the vowel ee than by the vowel oo. For we may here note that, as Helmholtz proved, the difference between the various vowel tones—every one of which may be sung on one and the same note—depends upon the variation in their over-tones. It appears that in the case of vowel production the over-tones are produced partly in the mouth itself. It would seem to be a conclusive proof of this fact that we are able to whisper the vowels.

When a noise or musical note is made to which the flame responds, it will quiver in greater or less degree, or may actually be so much shortened as almost to disappear. The instant that the noise to which it objects ceases, it jumps up again.

Analysis of Vowel Sounds. The German physicist König has utilised these facts in order to make what he calls a *manometric flame*. If we take a series of Helmholtz's resonators and attach them to the manometric flame apparatus of König, it is quite easy to analyse any compound tone or clang [see illustration]. The diagram shows how the sound is made to throw a membrane into vibration, on the far side of which the gas, as yet unlighted, is passing upwards towards the flame. Now, in order to observe the movements of the flame, which are very rapid, it is necessary to look at its reflection in a rotating mirror. During silence this simply forms a long band of light, but it is broken up into various forms according to the sounds that are produced. These may be extremely complex in their shape in accordance with the complexity of wave form of the sound that is being produced: and there is the coincidence that might be expected between the form which the altered flame takes in the mirror and the



form of the marks produced by the needle of a phonograph under the influence of the same sound.

Now, it is especially by this admirable combination of the devices of Helmholtz and König that it is possible to analyse completely the nature of the various vowel tones. But even this method has lately been superseded, or, at any rate, supplemented, by the application of photography to the phonograph, and the subjection of the curves so obtained to mathematical analysis. The consonants, by the way, are mere noises.

Harmony and Discord. Finally, we may note a few of the simpler facts of harmony and discord; and, in the first place, we must observe the peculiar phenomenon called *interference*, of which much more must be said when we come to consider waves of light. Interference is a phenomenon common to all forms of wave motion, and everyone has observed some consequence of it who has watched the rebounding of waves from a breakwater. Everyone knows how, when the two crests, the one of the advancing and the other of the rebounding wave, coincide, the water is very much raised The case is similar if two stones are thrown side by side into a pond. On the other hand, where crest and trough meet one another, they neutralise one another. This is why the phenomenon is called *interference*.

The musician knows interference because of his familiarity with what he calls *beats*. When two notes—as, for instance, two low notes on the organ—are sounded together, we get an unpleasant effect of sudden reinforcements of the sound called beats. In such cases we always find that the two notes are really very near one another—perhaps nearer one another than any two notes on an organ in tune can possibly be. These beats or throbs constitute the ultimate basis of discord. Now, discord is usually taken as synonymous with disagreeableness of sound, but the question of pleasantness or otherwise of sound is a matter of taste, and therefore not open to dispute. It all depends on the number of beats which the individual ear can tolerate. Not only so, the occurrence of discords is of immeasurable musical value. As Browning says, "Why rushed the discords in but that harmony should be prized?"

"Out of Tune." One interesting fact remains to be noted. We have strongly insisted upon the constant and necessary character of the simple relation between the various notes of the scale. It was observed that the most beautiful note might be produced during the playing of any piece of music, but that if such a note were not actually in the scale—in other words, if it were what is called "out of tune"—it could have absolutely no musical value. These simple mathematical ratios are fundamental to music, but, in the case of an instrument such as the piano, it can easily be shown that, if we are to insist upon this, it will really be impossible to construct a piano at all; or, at any rate, it would be possible only to construct a piano that was in tune for one key—obviously a piano on which it would be possible to play only the simplest tunes. If the ratios for the key of C are exactly those which we have quoted, then it is impossible to obtain the same ratios for the key of D. Hence, there is adopted the device which is known as *equal temperament*, which effects a compromise between all the possible keys, so that, in whatever key we are playing, the ratios of its notes are equally near to—and far from—the perfect ratio. The ordinary ear cannot perceive the small departure from true intonation. Such a difficulty does not occur in the stringed instruments, where the player makes his notes as he goes along. One of the delights of the Joachim Quartet—playing by themselves—is that the players play absolutely in tune. If they play a quintet with a piano, the difference can be observed by good ears.

GEOMETRICAL DESIGN: NETWORKS. ALL-OVER PATTERNS

GEOMETRICAL DESIGN

Its Origin and Application. Groups. Explanation of Terms. Networks. All-over Patterns. Borders

Continued from page 2188

By WILLIAM R. COPE

Primitive Design or Ornament. Although geometrical ornament is more abstract than that founded on natural forms, yet it is the oldest, as is shown by the primitive art of savage races of past and present times. No doubt this is so because geometrical ornament is easier, and requires less artistic skill than conventional arrangements of natural forms. Probably sewing with a thread suggested the zigzag line, the wave that of the wavy line, the woven work led to reticulated patterns, the plaited hair to that of the plaited band. The revolution of a fork gave the circle, the combination of dots at regular intervals suggested the polygons or pointed stars. The gradual development of these original geometrical forms, due to the growth of culture and knowledge, led finally to such geometrical artistic forms as are seen in Moorish panelled ceilings, in Gothic tracery, in the guilloche pattern, etc.

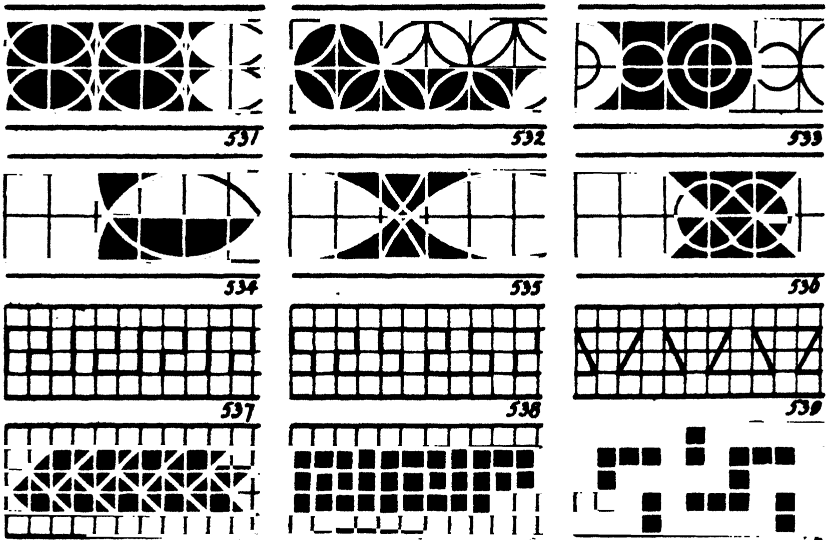
Application of Geometrical Design. The laws of geometry appear to have controlled the beautiful artistic designs of the ancient Greeks, and the decline of art in the different ages can be traced to neglect. Few workers seem to realise how universal are the applications of geometry to artistic ornament, such as is used in architecture, wall decoration, mosaics, parquetry and marquetry, tiles, floorcloths, carpets, pottery, metal-work and jewellery.

Groups of Geometrical Ornament. Geometrical ornament may be generally divided into three groups: First, when the ornament is in bands or borders, as in **528** to **560**; secondly, when it is repeated in patterns over an unlimited space, as in diapers [**510** to **527**]; and thirdly, when the ornament fills an enclosed space, as in panels of various shapes.

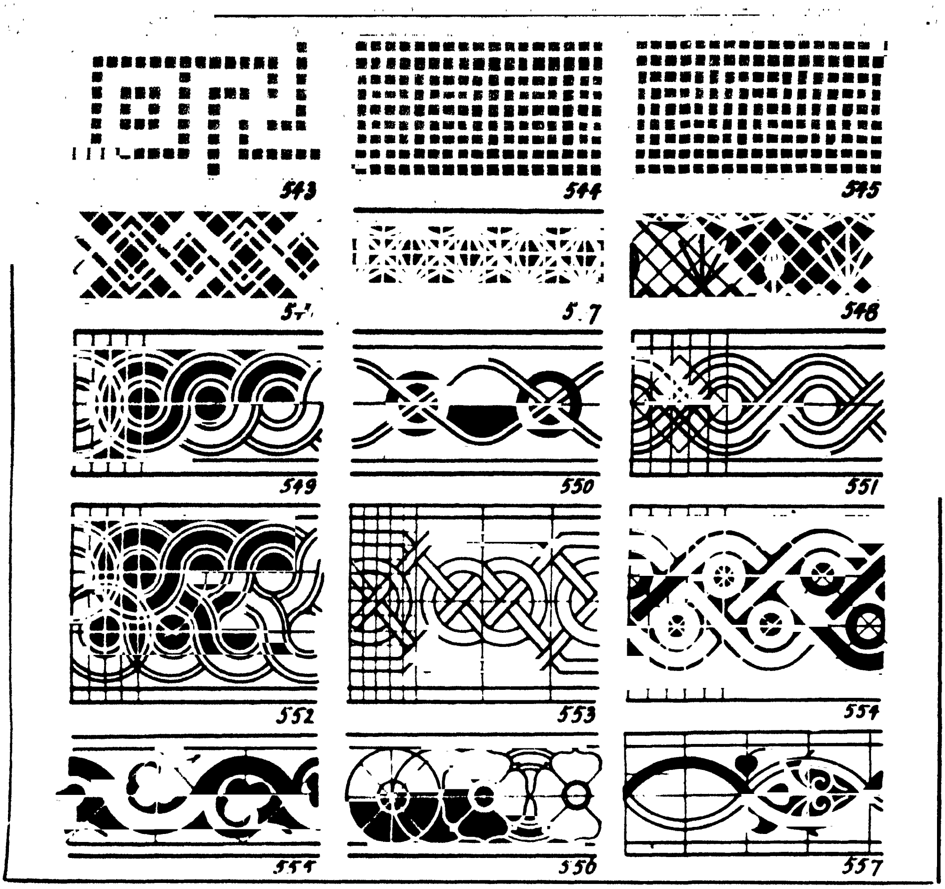
The designs here given are not by any means exhaustive, but are suggestive of the many variations that can be made in geometrical forms. The student, after copying them as exercises, should endeavour to design suitable variations in order to develop his ingenuity and taste.

Explanation of Terms Used. *Repetition* is a succession of the same form. This becomes monotonous if not varied, and for this reason the curves are introduced among the interlacing straight lines in **558**. In **547** the nailhead shape is *repeated*. When the same shape is repeated in an opposite direction, it is said to be *reversed* or *contrasted*, as in **527**, where the left-hand half of the repeat is reversed in the right-hand half of the same repeat.

Symmetry is the repetition of any form on its axis, as in **527**, where the central vertical



BORDERS: INTERLACED PATTERNS, GREEK FRETS



BORDERS: GREEK FRETS, CHAIN, NAILHEAD, GUILLOCHE, AND OTHER PATTERNS

line in each repeat is the axis. This principle of symmetry is one of the most important for producing ornament.

The *unit of design*, or *unit of repetition*, is the whole ornament in each repeat, as in **547**, where each nailhead is the unit of design.

Kinds of Network. The construction lines used in setting out geometrical patterns are arranged to form a *network* in order to secure accuracy of construction and repetition. This network is of various kinds. The most frequent are quadrangular reticulation, as in **504** to **507**, in which **505** is the *diamond* or *lozenge* net, and **507** is a combination of the square and diamond, while **508** and **509** illustrate the equilateral triangular network.

It will be seen that the square net has been used in **510** to **524**, and **527** to **545**, the diamond in **525**, **526**, **546** and **548**, and the triangular net in **561** to **574** [see next lesson]. These different nets may be easily and accurately constructed by means of the T-square and set squares of 45 deg and 60 deg. It is of course essential that the network should be very accurately made, otherwise patterns, especially those containing circular forms, will not repeat and fit properly.

All-over Patterns Founded on the Square Net. In **510** to **527** are shown examples of "*all-over*" patterns, as they are sometimes called. The designs in **510** to **523** would be suitable for window glazing, without further enrichment. They are also construction lines for richer patterns for carpets, tapestry, ceilings, etc. Figs. **524** to **526** suggest arrangements for parquet flooring. It will be noticed that **511** and **514** are similar to tiling arrangements for roofs, and are "*scale*" designs. In **527** the black and white forms are the "*ogee*" pattern.

Bands or Borders with the Square Net Foundations. These are not limited with regard to length, and are generally narrow, ribbon-like ornament. The principal patterns in this group are: The Fret, as in **537** to **545**; Chain, as in **546** and **550**; Interlaced patterns, as in **531**, **536**, **550**, and **553**; the Guilloche, as in **549**, **551**, **552**, and **554**; and Foliated Bands in the forms of Rosette [**556**], Flower, Leaf, Scroll [**555** and **557**], etc. There are also the Greek Wave scroll, the Leaf, and the Egg and Tongue pattern, which will be illustrated later.

ROAD DRAINING & LAYING

Draining the Road. The Dumb Well. Various Types of Gullies and their Uses. The Steam Roller. Channelling and Kerbing

continued from page [illegible]

By A. TAYLOR ALLEN

Draining the Road. Suburban and country roadways are often rendered impassable after heavy rains from the want of proper drainage. Deep ruts are formed, which become channels for the water, and there is no escape for the rainfall. One of the simplest modes of draining a country road in localities where gravel or stone may be had is to lay horizontal drain-pipes below the gravel, so that the rain will pass through to them. A good-sized pipe-tile is laid at the bottom, surrounded by small stones. On this coarse gravel or loose stones, such as quarry chippings, are laid, and above this a layer of fine gravel, then the surface gravel.

Such a drain in the centre of the roadway will often be sufficient, but for wider roads two lines of drains may be made. At all the depressions in the road, outlets must be made for the discharge of the water from the drain tile to the roadside, or natural channels, which cross the line of road. A properly compacted foundation, laid to a good inclination or section, and a well-metalled roadway and footpaths, throw off the water uniformly, and require only a few well-placed gullies to carry off the surplus rainfall.

Importance of Road Draining. Too much attention cannot be paid to the drainage of roads. When footpaths are constructed, a channel or watercourse is formed to receive the water which results from curving the transverse section of the road, and gullies are placed to about every 40 lineal yards of sewer, and at every intersection of streets, to convey the water through 6-in. pipes into a properly constructed sewer having a suitable outfall. In country roads, where there is no footpath or sewer, water tables (the width of a roadman's spade) should be cut obliquely at intervals to convey the water from the channel at the side of a road into a ditch or watercourse, thus carrying the water off before it can filter through the surface of the road.

The Dumb Well. When there are no natural outlets for the water, such as ditches, ponds, and watercourses, a *dumb well* is constructed under the path. This kind of well is dug and steined on the underpinning principle. The excavation is carried down as far as it can safely be taken without steining. An elm curb, made in two or more thicknesses, lap-jointed and cut circular, is then laid at the bottom, and the brickwork is built thereon. The excavation is then continued inside the curb. The earth supporting the curb is then cut out, with the exception of a few piers, a firm footing of timber is made in the centre of the bottom, and raking struts are put in to carry the curb; after which the piers are cut away, a new curb is put in, and the brickwork is carried up and pinned in under the old curb, which is left in position. In practice workmen often use more rough-and-ready methods, at considerable risk.

The well is then either domed right over in brickwork, or partly domed over, leaving an opening of about 2 ft. square for cleaning purposes, this opening being covered with a 3-in. York stone.

Road Drainage with Pumped Sewage. In a town or district where all sewage has to be pumped, it is of great advantage to keep the volume as low and as constant as possible; it would therefore be better to have a separate system for surface water. To give an idea of the enormous saving which would be effected in a district of this kind if the whole of a rainfall of 1 in. per hour were kept out of the foul sewers, and a 1 h.p. pump sufficed to lift the volume, it would require a 60 h.p. engine and pump to lift this large quantity of rainfall if the whole found its way to the foul sewers.

The table below is given, as rainfall plays a very important part in the designing and construction of storm and surface-water sewers.

The annual rainfall in England varies from 20 in. to 70 in., the average being 40 in.

The greatest rainfall in England in 24 hours = 3 in.

The greatest rainfall in England in one hour = 1 in.—in rare cases 1¼ in. and 1½ in.

⅛ in.	of rainfall	= ·585	gal.	per yd.	superficial
$\frac{3}{16}$ in.	„	= ·878	„	„	„
¼ in.	„	= 1·171	„	„	„
$\frac{5}{16}$ in.	„	= 1·463	„	„	„
⅜ in.	„	= 1·756	„	„	„
$\frac{7}{16}$ in.	„	= 2·049	„	„	„
½ in.	„	= 2·343	„	„	„
$\frac{9}{16}$ in.	„	= 2·635	„	„	„
⅝ in.	„	= 2·928	„	„	„
$\frac{11}{16}$ in.	„	= 3·220	„	„	„
¾ in.	„	= 3·514	„	„	„
$\frac{13}{16}$ in.	„	= 3·806	„	„	„
⅞ in.	„	= 4·099	„	„	„
$\frac{15}{16}$ in.	„	= 4·395	„	„	„
1 in.	„	= 4·687	„	„	„

The following is a digest of the clauses for the preparation of a specification for this class of work:

Each length of sewer shall be laid in a perfectly straight line both in the horizontal and vertical planes, the levels and gradients shown upon the drawings being rigidly adhered to unless otherwise ordered in writing; and every pipe shall be accurately boned in with a proper boning-rod arranged between two fixed sight-rails.

The lateral position of the pipes or concrete tubes must be kept true by means of a cord or wire stretched in the trench close to the proposed position of the pipes.

The pipes, concrete, and brickwork shall be laid upon an even and solid foundation.

On the completion of each length of pipe-laying or other work, after the same has been examined and approved by the engineer, the excavations are to be at once filled in over and around the work, and the ground is to be made up to the required level.

In closing up all trenches selected earth or sand free from stones, lumps, or other hard substances more than two inches in diameter, shall be carefully shovelled into the trench to a depth of 1 ft. above the crown of the sewer. This material shall be solidly rammed down on both sides of the pipes so as not to disturb them. In the case of stoneware pipe sewers in trenches over 6 ft. deep, the earth shall not be thrown direct on the pipe, but shall first be shovelled on to a portion already covered and then passed along on the uncovered portion by a labourer in the trench.

All timber used for shoring or other purposes shall be carefully drawn as the work of filling-in progresses, and never in such a way as to allow the side of trenches to cave in or slide.

The trenches shall thereafter be filled up in layers of 9 in. deep, each layer being well rammed down over the whole surface before the next layer is filled in.

Walking over sewers shall not be allowed until they have been covered with at least 1 ft. of earth. All boulders, rocks, stones, logs, and other objects of over half cwt., and such other materials as the engineer may deem unsuited for filling, shall be considered as waste material.

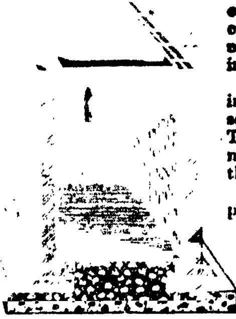
The contractor is to consolidate the ground filled in with a copious supply of water.

The joints of all pipes shall be well and truly made with Portland cement. The cement mortar used for this purpose to be in the proportion of one of washed sand to two of Portland cement, with a fillet of the same worked round the outside, the joints having been previously filled in with gaskin dipped in tar, rammed in so as to fill the extreme end of the space between the socket and the pipe for a depth of at least ¾ in. all round.

A proper tool with circular blade and long handle shall be used to take off and clean out the superfluous cement from the inside of the pipes.

All brickwork of manholes shall be executed in the most workmanlike manner; each course flushed in, grouted, and finished solid; the courses run parallel, or, where curved, evenly and uniformly to the curvature of the work, and centres in neat, close, and regular joints struck neatly and flush with the face of the work. In the case of work built on centres the joints shall be carefully cleaned off and finished upon the removal of the centres.

The manholes shall be constructed with square chambers. The foundations and floors shall be formed in cement concrete, properly shaped to the forms shown on the drawing. The floors of the manholes shall be rendered 1 in. thick in cement mortar, the whole being carefully constructed to the exact forms and gradients shown on the drawings. Semi-circular channels shall be formed in the concrete floors, and where two or more sewers enter a manhole the channels shall be curved so as to lead the sewage from one sewer into another with as little interruption to the flow as possible.



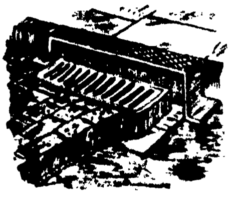
3. BRICK GULLY TANK

The walls and arches shall be built in brickwork and backed up behind solid with filling of approved material. The bricks shall be carefully cut and made good where the sewer pipes pass through.

Every manhole shall have cast-iron plates inserted in the arches where they are cut away to form the entrance to the manholes.

The covers shall be of the patterns shown and described, and they shall be carefully set to the slope of the ground surface.

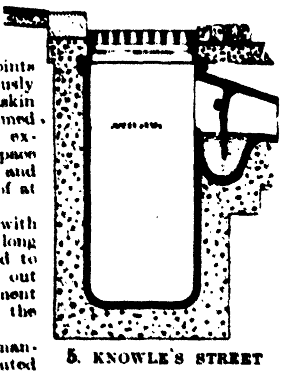
Foot-irons shall be inserted and fixed in every fourth course of the wall, extending through the brickwork, and turned up so that they cannot be drawn.



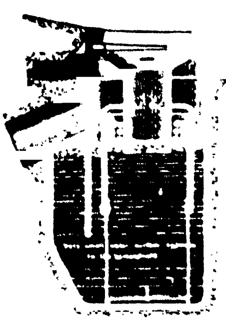
4. GULLY, SHOWING KERB OVERFLOW

Gullies. For roads and streets where *paved* channels are formed, iron or stoneware gullies, covered with iron gratings and frames, are used. A great number of different descriptions and types of gullies are on the market, and it is impossible to go into the merits of all, but they should be of such form, materials, and dimensions as the necessities of the case require.

For country roads and by-roads, where cost is a consideration, a suitable brick tank [3] can be constructed to hold a considerable quantity of the silt or detritus, which is carried down by every rain off such roads. The form and size can be decided upon only by the necessities and requirements of each case. The principal objects to be considered are:



5. KNOWLE'S STREET GULLY



6. DURRANT'S PATENT STREET GULLY

(*a*) Sufficient area of open grating surface to carry off heavy rains and storm water.

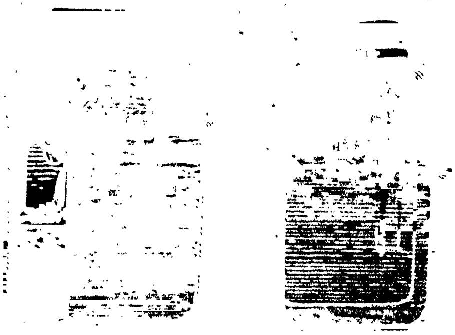
(*b*) Sufficient cubical contents of the gully to retain road detritus and silt below the outlet, to prevent their being carried by the water into the sewer.

(*c*) A good water-seal or trap to prevent the escape of sewer gas.

The gully tanks should be carefully bedded and fixed in their position, and the connection to the drain-pipes made with a cement joint.

The weir, or kerb overflow [4], is to be fixed at such a height as to bone into the kerb height, and also of the channelling, so that the water may flow freely over the weir. The cover should be bedded on brickwork set in cement, and the top should be laid flush with the pavement.

Figs. 5, 6, and 7 illustrate certain types of gullies, and show their method of fixing. Figs. 8 and 9 illustrate gully gratings for brick and stoneware tanks.



7. CROSTA'S PATENT SURFACE WATER GULLY

Subways for Pipes. Although subways for underground pipes originated in the City of London about the year 1860, during the time the Holborn Valley and other improvements were effected, very little progress has been made in the development of the system.

London subways, it is true, are the most complete of their kind in England, and are in size 16 ft. wide by 7 ft. 6 in. high, 12 ft. by 7 ft. 6 in., and 8 ft. by 7 ft. Nottingham has some most convenient subways, but nothing of the kind is to be found in Manchester, Liverpool, Birmingham, and other great centres, though, about 1895, the city engineer of Manchester prepared a scheme for subways under a section of new streets in that city at an estimated cost of £51,000 per mile.

Provincial Subways. In one of the principal subways in Nottingham the following pipes and cables are accommodated: One 15-in. sewer, two gas mains about 8 in. diameter, two water mains about 4 in. diameter, telephone cables, telegraph cables, and twenty electric cables.

To show the value of such works, in Victoria Street, Nottingham, in which is situated the General Post Office, there are, besides the gas and water pipes and connections, not less than six pipes containing telegraph wires in this subway, and not one single stone was disturbed or the carriage-way broken up for twenty-five years, and in that period not one single penny was spent on repairs in that street.

Visitors to St. Helens can hardly escape the conviction that there is one other borough in which experimental undertakings of subways are ventured upon.

8. GULLY GRATING

It is, in fact, an agreeable surprise to find a comparatively small provincial town actually and successfully leading the way in an experiment which but a few years ago was often regarded with ridicule.

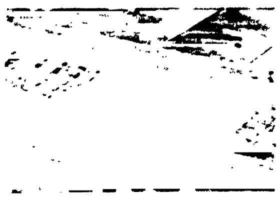
Construction and Cost. These subways are constructed wholly of concrete, with the exception of a 4½ in. ring of the brick to form the arch, and are 6 ft. 6 in. high by 5 ft. 6 in. wide, and contain one 18 in. gas main, one 10 in., and one 6 in. water main, with provision for telephone and electric light cables. The cost of these subways was £7 2s. 4d. per lineal yard, this amount including all the lateral ways and the electric lighting throughout.

In 1901, beneath the City of London streets, there were 2,540 lineal yards of subways under the control of the City Corporation, in addition to 1½ miles not controlled by that authority. The length of gas, water, and hydraulic mains, telegraph and other tubes laid in the corporate subway amounted to nearly nine miles. The electric light and telegraph conduits alone contain some hundreds of miles of wires and cables.

Value of Subways. All engineers to municipal authorities are agreed upon the theoretical desirability of constructing underground subways for the reception of all sewers, gas, water, and electric mains, telephone and other wires, so that the operation of the local authorities, gas, water, telegraph, electric lighting and other companies, in laying down, renewing, maintaining, repairing, testing and inspection of their mains, pipes, cables, wires, and services may be facilitated and the existing inconvenience arising from the opening of the roads obviated.

Steam Rolling. The invention of steam rollers, so far as any practical results were obtained, was effected by Mr. William Clark, the City Engineer of Calcutta, and the late Mr. Fothergill Batho, of Westminster, who took out a joint patent for a steam roller in 1865. The first constructed rollers were generally 15 tons in weight, although one of 30 tons was built for the Liverpool Corporation, and, although not used latterly, was broken up only in 1890.

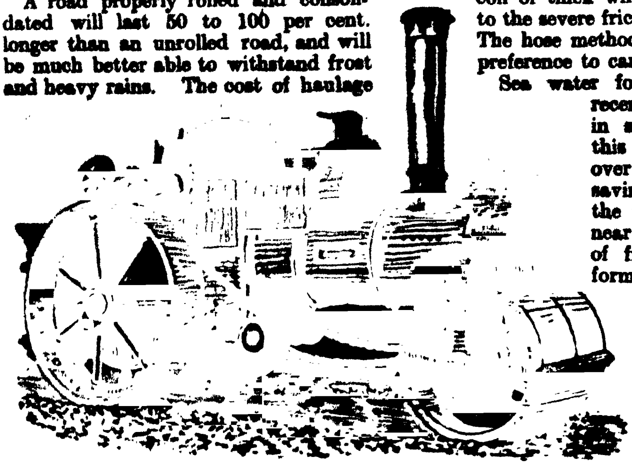
In 1865 a trial was made in Hyde Park by Messrs. Aveling and Porter in steam rolling. An ordinary traction-engine had its wheels exchanged for heavy and wide roller wheels. The trial was considered a success, and the next improvement was the roller supplied by this firm in 1867 to Liverpool [11]. A modern roller is illustrated by 10.



9. GULLY GRATING

Capacity of the Steam Roller. By the use of steam rollers some 2,000 superficial yards per day can be efficiently rolled at a total cost of one-third of a penny to one-fifth of a penny per sq. yd. By the use of the roller the road is made at once; the stones which compose it, while still sharp, are driven at once into their places, to the infinite comfort of the horses and men who have to traverse it.

A road properly rolled and consolidated will last 50 to 100 per cent. longer than an unrolled road, and will be much better able to withstand frost and heavy rains. The cost of haulage over its surface will be lower, and the amount of road detritus removed from it will be less.



10. MODERN STEAM ROAD ROLLER

Specification. The Local Government Board sanctions loans to urban and rural district councils for the purchase of rollers, spreading the payment over 10 years.

The following is a digest clause for a specification for steam rolling a new roadway when the work is done by contract:

> The contractor shall include in his prices for a 10-ton steam roller attendants, sweepers, and water for well watering, rolling, and re-rolling the roads throughout after applying each coat, beginning with the chalk or hard core, which must be thoroughly consolidated, and all slack spaces filled in with the same material and rolled before the next coat is applied.
>
> The finished coating to be well rolled in and consolidated, a sufficient quantity of binding material being used for binding; the whole to be well watered, steam rolled, and finished to a true and even surface, new flints being from time to time added to adjust any irregular places.
>
> The road surface to be left smooth, firm, and compact, and to the contour as shown on sections.

Watering. Roads are sprinkled with water during the dry season for the purpose of supplying moisture to the surface, essential to ensure the best wearing results of macadamised roads.

The water is usually distributed by water-carts, a two-wheel cart holding from 220 to 300 gallons, and a four wheel van 400 to 450 gallons, the carts being filled from street hydrants [12].

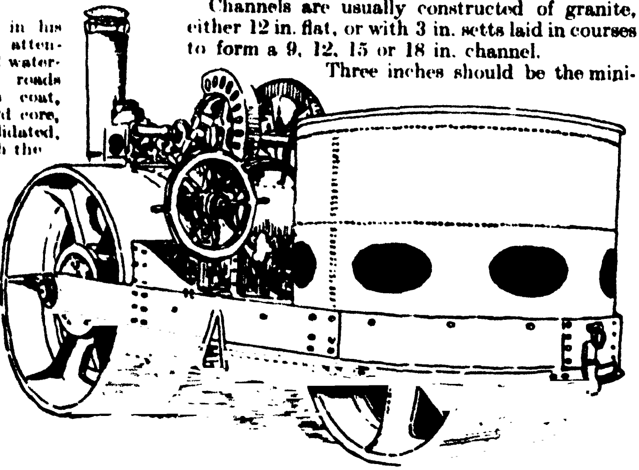
In Paris, and a few towns in this country, watering is frequently done by hose attached to the fire hydrants in the street. Metal pipes with flexible joints are generally adopted, or, if hose-pipe is used, it should be protected by a coil of thick wire. Ordinary hose-pipe, owing to the severe friction it receives, soon wears out. The hose method is not to be recommended in preference to carts.

Sea water for road watering has during recent years been largely employed in seaside towns. Salt water for this purpose has some advantages over fresh. There is a considerable saving in the cost of sprinkling by the use of salt water when it is near at hand as compared with that of fresh; one sprinkling of the former will lay the dust for a length of time that would almost require two or three sprinklings of the latter. A road, after being sprinkled once or twice with sea water, will remain free from dust for some time after the road is practically dry, as the deliquescent salts contained in the water form a hard crust, which in a measure preserves the surface.

Channelling and Kerbing. Channelling, also known under the technical term of *gutter and water tables*, are essential for all roads to carry away the water.

All channels should be from 12 to 18 in. wide, and laid on a 4 in. concrete foundation, and well grouted in with liquid Portland cement or cement and sand.

Channels are usually constructed of granite, either 12 in. flat, or with 3 in. setts laid in courses to form a 9, 12, 15 or 18 in. channel.



11. STEAM ROAD ROLLER OF AN EARLY TYPE

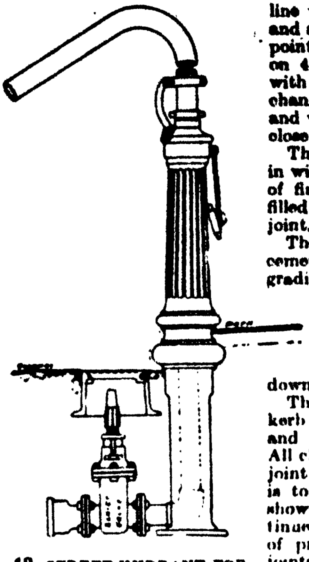
Three inches should be the minimum thickness for any class of street. At the crossings or intersections of streets it is advisable to keep the channel level with the kerb, to enable pedestrians to step off the path on to the crossing without a drop; this can be readily done by using granite pitchers around the corner, and allowing one edge of the pitchers to butt against the kerb, the other edge of the pitchers tilting towards the crossing, as it is very seldom that water has to be carried at these points.

Materials Used. The chief granites used are Aberdeen, Guernsey and Norwegian, costing 2s. to 2s. 4d. per lineal foot, 4 in. in thickness, 12 in. wide on a concrete foundation, and stones—Keinton, Purbeck and Shamrock—of the same dimensions, costing 1s. 6d. to 1s. 10d.

All footpaths should have a kerb on the outer edge to act as a sill for raising the path above the water flowing along the channel, and to retain the foundation and surface of the path.

The most usual kerb is a dressed granite, such as an Aberdeen, Guernsey or Norwegian, 12 in. wide by 6 in. deep, costing from 2s. to 2s. 6d. per lineal foot, laid complete on a concrete foundation, though in a country district an undressed granite 4 in. wide by 9 in. deep, costing from 1s. to 1s. 6d. per lineal foot, may be substituted, but this certainly looks a little rustic, and has not the workmanlike appearance of a dressed kerb.

Kerbs are also made in blue Staffordshire stoneware in either a bull-nosed, splayed, O.G., or solid pattern of various sizes. A kerb can also be constructed of cement concrete blocks, or with concrete *insitu*, by means of plank moulding rigidly fixed in place, and removed after the concrete has set. This kerb is suitable for a street of poor class property where it is essential to study economy.



12. STREET HYDRANT FOR FILLING WATER-CARTS

The concrete should be of the best materials—*i.e.*, good Portland cement and thoroughly clean shingle, ballast, or broken stone in proper proportion and well mixed.

In France wrought and cast iron kerbs are used, and these have recently been introduced in some towns in England.

In America fireclay brick kerbs of various shape have been used with success.

In laying kerb it is very important that an experienced man possessing a good eye should be employed to make it appear pleasing to the eye both as regards line and level, as kerb laid the least irregular is very perceptible.

The "skillet line" and "boning rods" are used to assist in securing a straight or curve line.

It has been held that a local authority has no power to compel the kerb of a footpath to be laid in a new street before building operations are commenced.

Specification. The following is an abbreviated clause for the specification:

> Lay the granite kerb in a dead straight line with uniform longitudinal gradients, and so as to bone accurately through from point to point. The kerb is to be laid on 4 in. of cement concrete, 15 in. wide, with a fall of ½ in. outwards towards the channel, each stone to be bedded solid and well beetled down into position with close butt joints.
>
> The butt joints are to be well grouted in with one part of cement to two parts of fine sand, each joint to be completely filled and finished with a neatly-cut joint.
>
> The channelling is to be laid on 4 in. cement concrete, 12 in. wide, to uniform gradients 4 in. below the top edge of the kerb, except where otherwise specified or directed by the engineer, and with a cross fall of 1 in. towards the kerb, each stone bedded solid and well beetled down into position with close joints.
>
> The butt joints and the joint between kerb and channel are to be grouted in and finished as specified for the kerbing. All channelling to be laid so as to break joint with the kerbstones. A circular kerb is to be accurately laid in the position shown upon the drawings, so as to continue the line of kerbing in a uniform curve of proper radius, with proper radiating joints, which are to be accurately fitted on the spot if necessary.
>
> Where kerb has to be relaid it is to be carefully taken up and relaid on concrete in the manner described for new kerb, and lowered or raised to new level as required.
>
> Any existing kerbstones which the surveyor may deem unsound or defective is not to be reused. The contractor is to include in his price for reworking, back-jointing, and squaring ends of any kerbs which have to be relaid.
>
> All gully tanks to be supplied with 6 in. outlet and movable grating of strong bars, each grating to weigh not less than 2 cwt. 25 lb.
>
> A row of granite setts laid as headers on cement concrete 4 in. in depth, and grouted as specified for channelling, to be laid around all gully gratings, and splayed at each end to meet the water channel.

All kerbing and channelling should be laid previous to the formation of the carriage-way.

AN EMPIRE COAT

Drafting and Making an Empire Coat. Materials Required and Measurements. How to Cut Bodice for a Stout Figure. Making Up

By Mrs. W. H. SMITH and AZÉLINE LEWIS

THE Empire is a very popular style at the moment, and is equally suitable for street or evening wear. Its principal feature is a short body of a slightly loose fit extending about 4 in. below the bust, which lends itself to various modes of trimming [78].

Materials Required. From 2¼ to 3 yd. of 54-in. cloth, ¾ yd. sleeve lining, and 4 yd. single-width for bodice and skirt; ½ yd. canvas.

Measurements. This is drafted to a back length of 16 in.; chest, 34 in.; sleeve, 20 in. from centre-back to elbow; elbow to wrist, 10 in. Working scale, half chest (17 in.); ¼ in. turnings are allowed on all seams.

78. EMPIRE COAT

The Drafting. For the system, see Ladies' Princess Robe.

Square the lines at right angles from A, B, and C, as in previous draft [67]. C to D, 4 in.; this is for the short waist, and can be made shorter or longer as desired. D to 1, 2 in. Draw line from 1 to A. Back line to C^a, one-third of chest (5⅔ in.), on to F, two-thirds less ½ in.; on to G, half chest (17 in.); G to H, 3 in.; C^a to I, one-twelfth (1⅜ in.). Square line up from C^a to B line; make J ½ in. above the line; J to J^a, half the distance from A to C [see broken line]. This is the back pitch of sleeve. Draw shoulder line from J to A_b, and neck curve from A^b to A. Square up from F, make F^a one-fourth of chest, plus ¾ in. (5 in.); F^b, midway between; F^b to X, ¾ in. Draw line from I to K, half the chest plus 3 in., K to 2, 1 in. Square up from G, make L on neck line, continue neck curve, shoulder, and armhole curve as in previous draft; draw line from K through H to H^a. This should not be so wide if the bolero is to be left open to show the blouse.

Back line to I^a, half chest, 8½ in. Square line down from I^a to short waist and make a dot; 3 and 4 are ¼ in. to the left and right of the dot. Draw lines from 3 and 4 to I^a. Three-quarters of an inch up from bust make a dot on armhole curve for inset of sleeve.

Raise A and A^b ¼ in., connect A^b to shoulder line. M^a to S, ¼ in. This is to form a little stand for the neck, but if it is not to fit closely the two last additions are not needed. Make a dot 2 in. to the left of H^a and draw line from H through the dot to S. Draw line from 2 to H. The broken lines indicate the position of trimming [79].

To obtain a shaped trimming to simulate a collar, place the shoulders together evenly and trace through the broken line—this can be made deeper if desired.

When cutting the collar avoid having a seam in the back. The trimming can be of galoon, braid, lace, silk, velvet, or embroidery.

Trace the pattern off. The front must be traced from 2 to H on to S, unless a rever is desired. In this case it must be traced round H^a. This drafting will do for the bolero in *d*, 71 [page 2205].

Skirt for Coat. Square lines at right angles 2 in. down from top of paper, and 5 in. in from edge; letter the corner D. D to E, 11 in.; D to 1, 2 in; 1 to 2, 1 in. Draw line from 1 through E; 34 in. down make E^a. 1 to K, 1 in. more than 1 to K on body draft. This extra inch is for easing on [80].

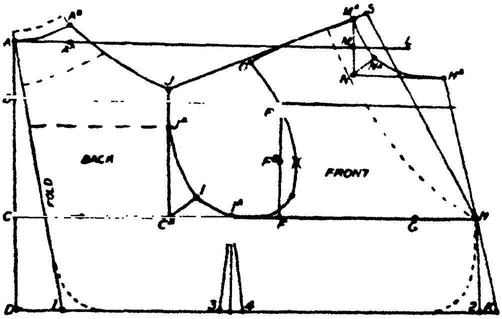
Square line down from K, 11 in., make dot 2 in. to the right. Draw line from K through the dot the length of skirt plus 1 in. (35 in.); make K^a. 1 to 3, 8½ in.—*i.e.*, 1 in. more than 1 to 3 on body draft. 3 to 4, 1 in.

Square a line down from the centre of 3 and 4, 11 in.; make L. Dots 5 and 6 are 2 in. to the right and left of L. Draw lines from 3 through 5 the length of skirt (34 in.); make M; 4 to N, the same. Draw lines from K^a to N and from M to E^a. Continue the lines from 1 to 2 and side lines from 3 and 4 to 1 in. above, and make 7 and 8. Curve from K to 8 and from 7 to 2. N to 8 is the front gore, M to 7 is the back gore. Trace the pattern off, round the outlines.

82. LARGE-SIZED BODICE

The sleeve is drafted as for ladies' tight-fitting jacket with the following exceptions: Five and a half inches are left on for extra fulness at the top, 3 in. at the elbow portion, and 3 in. at the wrist. The sleeve can, of course, be cut any length desired [see broken line in diagram 81].

In cutting the fronts of skirt, leave a 3-in. inlay for facing.

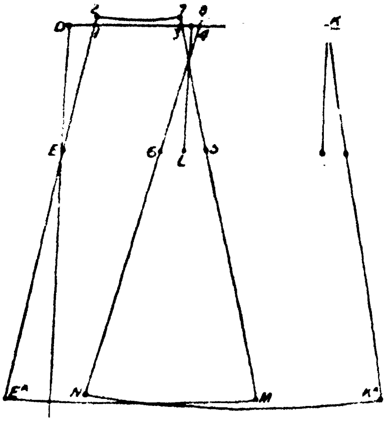


79. DRAFTING BODICE OF EMPIRE COAT

The bodice must have a facing cut to shape, about 2 in. wide. Chalk and thread-mark the various parts as in previous lessons.

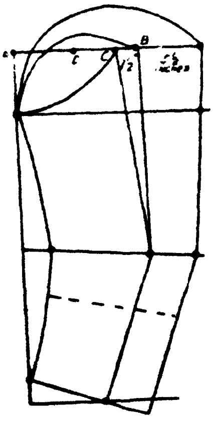
The Making. Baste the canvas to the fore parts of bodice, and put the linen stay on as previously shown.

The facing must be put on, stitched, pressed, and felled, as in ladies' coat. The question of fastenings must now be decided. If hooks and eyes, they must be put on before the facing is arranged; but if cord-loops and buttons, then the former must be sewn on when the facing is done. The neck must be stretched in the gorge to make it fit well at that part. Join the fore parts to the back; press, and trim the bodice portion according to taste or the prevailing fashion. The bodice is then ready to be lined.



80. DRAFTING SKIRT OF EMPIRE COAT

We now proceed with the skirt. A strip of canvas 2 in. wide should be put down the fronts, also a linen stay. Baste the facing to the canvas and fell, and proceed with the making as for coat.



81. SLEEVE FOR EMPIRE COAT

After having lined the skirt, the bodice must be attached to it in this manner. Place the edge of bodice to the edge of skirt, face to face, with the skirt towards the worker. Turn the linings of bodice and skirt back while basting together. Secure centre-back of bodice to centre-back of skirt. Now baste the skirt to the bodice, placing the side seams of skirt to the underarm seams and easing in the fulness that has been allowed.

Stitch and press, then baste the skirt lining to the bodice, and fell the lining of latter over the skirt.

The Sleeve. This is made as for coat, but the top part must be well eased at the elbow. The bottom can be gathered and put into a small gauntlet, or it can have small pleats about 6 in. deep. Should a three-quarter sleeve be preferred, it must be cut off at the broken line—*i.e.*, 4 in. down from elbow and 3 in. in front.

Care should be taken to keep all the edges as thin as possible, and it should be remembered that good pressing is essential.

Bodice for Stout Figure. The bodice given is for an erect stout figure, very hollow in the waist, and very full round the hips. The stouter the figure below the waist in front, the higher the waist line is thrown. The measures for this part must be taken very tightly under the bodice [**82**].

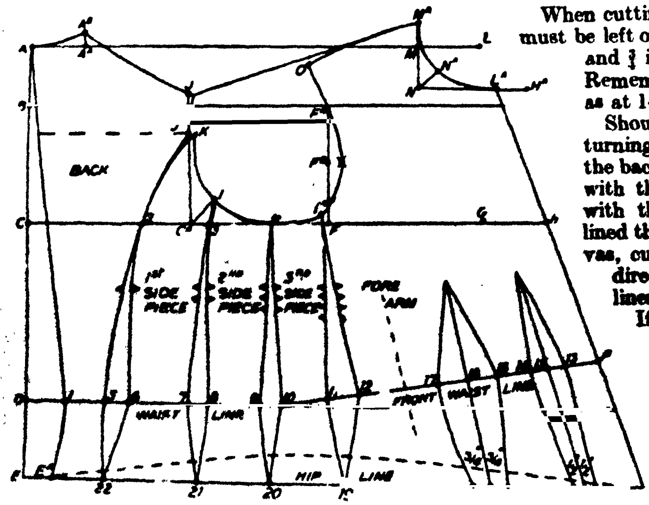
MEASUREMENTS. Neck, 15½ in.; length of back, 15¾ in.; chest, 40 in.; bust, 44 in.; waist, 31 in.; centre-back to elbow, 20½ in.; elbow to wrist, 10 in.; elbow 12 in.; wrist, 9 in.; front length, 19½ in. Working scale, half chest (20 in.).

It will be noticed that the indentation in centre-back is more than is given in previous lesson, which is due to the figure being so hollow at that point. For a stooping figure, the back is generally very much longer, and the front correspondingly shorter.

Square lines at right angles from A, B, C, and D, as in previous lessons [**83**] D to 1, 2 in.; D to E, 3 in.; E to E^a, 1½ in. Draw back line from E^a through 1 to A. Back line to C^a, one-third of scale less ½ in. (6¼ in.); to F, two-thirds less 1 in.; to G, half scale less ¾ in. (9¼ in.); to H, half bust plus ½ in. (22½ in.); F to F^a, one-fourth of scale (5 in.); F^b, midway between; F^b to X, ¾ in.; C^a to I, one-twelfth (about 1½ in.).

Square up from C^a to ½ in. above B line, make J; J to J^a, half the distance from A to C [see broken line]; J^a to K, ¾ in. Draw shoulder line from A^b to J.

Proceed as in first lesson to obtain neck curve, shoulder, and armhole, the only exception being that M^a should be 1 in. instead of 1¼ in. H^a to L^a, 1¼ in. Draw lines from L^a through H to hip line; M^a to P, front length less 2¾ in.—*i.e.*, the back neck measure as from A to A^b—F to I^a, ½ in. Divide the distance between back line and I^a into four parts, putting one-third plus ½ in. in the back, as at 2, and the remaining 7½ in. into three equal parts of 2½ in.; make dots 3 and 4.



83. DRAFTING LARGE-SIZED BODICE

Waist Suppression. 1 to 5, 1¼ in.; the side pieces should be ¼ in. less on the waist than on the bust line.

The Indentations. 5 to 6, 1 in.; 7 to 8, the same; 9 to 10, 1¼ in.; draw line from 10 to P (this is waist line proper); 11 to 12, same as 9 to 10. Draw the lines of side pieces and curve from 5 through 2 to J^a, and from 6 through 2 to K.

Measure up the waist of back and side pieces (total 7½ in.); place this amount on 12, and make a dot at half the waist measure. The distance from the dot to P (3½ in.) is to be taken out in darts.

P to 13, 2 in.; 13 to 14, width of first dart (1¼ in.); 15 in the centre; 14 to 16, 1¼ in.; 16 to 17, width of second dart (2¼ in.). We are allowing ¼ in. extra in the second dart as the waist stretches. 18 is the centre of 16 and 17.

Draw lines through the centre of each dart (parallel with front line) from hip to within 2½ in. of bust line; make dots ¼ in. to the right and left of first line (on hip line), and curve through 13 and 14 to top of dart. The dots on second dart should be ¾ in. to right and left, and curved in the same manner as the first. Now make a dot in the centre of 11 and 12. Square down from the dot and make 19 on hip line. Curve from 19 to 11 and 12. Treat the two next indentations in the same manner, making 20 and 21 on hip line, and 22 below 5, and curve to 5 and 6.

A wrap 1½ in. wide should be left on the front.

Sleeve. Refer to Ladies' Tailoring for sleeve of tight-fitting jacket, as we are giving the exceptions only. No turnings are allowed in this draft. Work to 1 in. less than half scale—*i.e.*, A to B, 9 in., instead of 10 in.; A to D, D to F, and F to H are each 4½ in. [84].

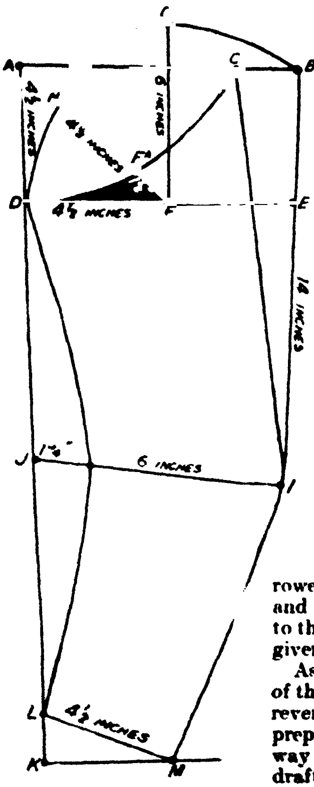
Cut out the pattern round the various outlines.

The Making. Chalk and thread-mark the patterns as in previous lessons, not forgetting to leave the inlays on shoulder and forearm, and to put in the balance-marks.

When cutting the fore parts, from ¼ to ½ in must be left on right fore part for buttonholes and ¾ in. on the left for button stand. Remember to stretch the back of darts, as at 14 and 17, when basting [83].

Should the material be ravelly, good turnings should be allowed, and, if thin, the back and side pieces should be lined with thin linen, stitched in the seams with the cloth. The fronts must be lined throughout with thin tailors' canvas, cut on the cross and inserted as directed in previous lesson. Place a linen stay along the edge, and press. If the bodice is to be buttoned, the right fore part must have a facing of material, 1½ to 2 in. wide, put on in the same manner as on the front edge of jacket.

The basque can be shaped as desired; for pointed bodice, see broken line. It should have a strip of linen on the cross about 1 in. wide, basted to the edge. Turn up the bottom and baste to lining and canvas, and well press the basque and fore parts. Insert the bones as in Princess robe. It is advisable to insert an extra bone in the fore part of this bodice [see broken line in diagram for position].



84. DRAFTING SLEEVE FOR LARGE-SIZED BODICE

Line the bodice as directed for coat and Princess dress. When felling round the basque, hold the facing a shade tight. The button stand and basque are generally faced with silk or Italian, the same colour as material.

The sleeve is made and inserted as in Princess robe; whilst the collar, which should be a little narrower, is also made and put on according to the directions there given.

As to the trimming of the bodice in 82, the revers and cuffs are prepared in the same way as those already drafted, and are made as directed in the previous lesson.

Continued

COOKERY RECIPES

Methods of Preparing and Cooking Various Breakfast Dishes, Cakes, and Beverages. Vegetarian Cookery. Kitchen Economy

continued from page 2197

BREAKFAST DISHES

Oatmeal Porridge

INGREDIENTS. One teacupful of coarse Scotch oatmeal, one pint of water, half a teaspoonful of salt.

Method. Put the water into a clean enamelled pan, add half a level teaspoonful of salt. Bring the water to boiling point. Dredge in the oatmeal and stir well, using a wooden spoon, or, better still, a Scotch porridge-stick, which resembles a small rolling-pin. Let it simmer about forty minutes, keeping it well stirred. If the oatmeal absorbs too much water and becomes too thick, add more. Serve quickly in very hot porridge bowls or small soup plates. It should be thick but not rocky. Serve with cold milk, cream, sugar, or salt. Prepared oats may be used, and take far less time to cook, though many prefer the ordinary oatmeal.

Brawn

INGREDIENTS. Half a pig's head, salt and pepper, four or more pounded cloves.

Method. Wash the head very carefully in tepid water and remove all the brains, veins, and splinters of bone. Next put it in a pan with enough cold water to cover it and two teaspoonfuls of salt; bring it to the boil, skim it well and let it cook steadily for from one and a half to two hours, or until the bones can be easily drawn out. Then take out all the bones, cut the meat into neat small squares; this should be done near the fire or the fat will set before it is finished. Put the meat on a plate, sprinkle it well with salt, pepper, and clove; mix well together, then pack it into a round mould or cake tin unless you have a proper brawn mould. Put a plate with some weights on the top of the tin to press the meat firmly together, and leave it till next day. Then dip the tin entirely into warm water, and the brawn will turn out easily. The liquor from it may be used for pea soup, and the fat from the surface may be clarified as will be directed later in the article on Kitchen Economies.

Buttered Eggs with Mushrooms

INGREDIENTS. A quarter of a pound of mushrooms, three eggs and one extra yolk, salt and pepper, a little milk, one ounce of butter.

Method. Stalk and carefully peel the mushrooms. Cut them in small pieces, put them in a pan with milk to cover them, and stew them gently till they are tender; then add to them the beaten yolk of the egg and one tablespoonful of milk, and keep this hot while the buttered egg is being made. Break the three eggs into a basin, dust them with salt and pepper, and beat them up. Melt the butter in a small pan; when it is hot pour in the eggs and one tablespoonful of milk, stir them quickly over a slow fire till they are lightly set. Have ready some neat pieces of buttered toast. Spread the mushroom mixture on them, then heap the buttered egg on that, shake a little chopped parsley on each, and serve.

Tomatoes, shrimps, anchovies, or kidneys may be used instead of mushrooms.

Scallops of Cold Meat

INGREDIENTS. Half a pound of cold meat or poultry, one ounce of butter, half an ounce of flour, half a pint of stock, browned crumbs, a teaspoonful of chopped parsley.

Method. Well butter four or six scallop shells. Chop or mince the meat. Melt half the butter in a small pan, stir in the flour smoothly; then add the stock and stir over the fire till the sauce boils. Season it carefully and add enough of it to the meat to make it nicely moist; stir in the parsley also. Put the mixture in the buttered shells, shake a good layer of browned crumbs over the top of each and put a few tiny bits of butter here and there on top. Put the scallops in the oven to get quite hot through, then serve them on a folded napkin.

Kidney Omelet

INGREDIENTS. One sheep's kidney, one and a half ounces of butter, pepper and salt, a quarter of a teaspoonful of parsley, a quarter of a teaspoonful of onion, two eggs.

Method. Break the eggs carefully, putting the yolks into one basin and whites into another. Work the yolks with a wooden spoon till frothy. Skin and core the kidney and cut it up into small pieces. Melt half an ounce of butter in a small pan, and cook the kidney in it; then add it, the salt and pepper, parsley and onion to the yolks, and mix well. Put one ounce of butter in the omelet pan (or a small frying-pan), let it get very hot and then brush it all over the pan. Now whisk the whites to a very stiff froth, add them to the other ingredients and mix very lightly. Pour the mixture into the pan. Place it over a quick fire for three minutes. Then put it in a moderate oven to set and slightly brown. Slip it out on a very hot dish. Fold one half over the other like an envelope and serve at once.

CAKES

Plum Cake

INGREDIENTS. Half a pound of butter, half a pound of castor sugar, three quarters of a pound of flour, one teaspoonful of baking-powder, six eggs, half a pound of sultanas, half a pound of mixed peel, a quarter of a pound of *glacé* cherries, a quarter of a pound of ground almonds, half an ounce of spices, one ounce of sweet almonds, half a gill of milk, half a teaspoonful of salt.

Method. Line a cake tin with two layers of greased paper. Cream together the butter and sugar. Whisk the eggs and add them. Sieve together the flour, baking-powder, and salt, then add them lightly to the eggs, etc. Prepare the fruit, chop the peel and cherries, and add them, also the almonds, spice and milk; mix all well together, put the mixture into the prepared tin, sprinkle an ounce of chopped almonds over the top, and bake it in a moderate oven for about one and a half hours.

Gingerbread

INGREDIENTS. Five eggs, half a nutmeg grated, a quarter of an ounce of ground ginger, a quarter of a teaspoonful of pudding spice, half a pound of castor sugar, nine ounces of flour, six ounces of peel, four ounces of almonds, a quarter of an ounce of carbonate of soda, two tablespoonfuls of milk.

Method. Whisk the eggs in a basin, add to them the spices and sugar, and beat well for five minutes. Sieve together the flour and carbonate of soda and add them; shell and chop half the almonds and add them, also the chopped peel and the milk. Mix all well together, turn it into a deep baking tin, which should be lined with greased paper; put the rest of the almonds, which should be halved, over the top, and bake it in a moderate oven for three-quarters of an hour. Watch it carefully, and if it begins to get too dark lay a piece of kitchen paper across the top.

Swiss Roll

INGREDIENTS. Three eggs and their weight in butter, sugar, and flour, two tablespoonfuls of milk, vanilla, one teaspoonful of baking-powder, jam.

Method. Cream together the butter and sugar. Sieve together the flour, baking-powder and a pinch of salt, then add these lightly to the butter, etc. Lastly, add the milk, spread the mixture in a shallow baking tin lined with greased paper, and bake it in a moderate oven till it is set and a delicate biscuit colour. Turn it on to a piece of paper which has been dusted with castor sugar. Warm a little raspberry jam in a small pan, spread it over the cake, then roll it up neatly; do this as quickly as possible, as if it gets too cold it is liable to crack in the rolling. Any jam that has no stones may be used.

Petits Gâteaux

INGREDIENTS. Half a pound of castor sugar, half a pound of ground almonds, two ounces of cornflour, six eggs, red currant jelly, two lemons.

Method. Brush some small fancy cake tins with melted butter, mix together two extra teaspoonfuls of cornflour and castor sugar, dust the inside of each tin with this, shaking off all that will not stick. Put the yolks of the eggs and the sugar in a basin and beat them till frothy, then add the almonds, grated lemon rind and juice, and lastly the cornflour. Whisk the whites of the eggs to a very stiff froth, and add them very lightly to the mixture. Half fill the tins with it, then bake them in a moderate oven till they are set. Take them out of the tins, and put them on a sieve to cool; when they have cooled slightly, scoop out a little from the centre of each, and put in a little piece of red currant jelly.

Bath Buns

INGREDIENTS. One and a half pounds of flour, half a pound of butter, a quarter of a pound of castor sugar, a quarter of a pound of granulated sugar, [illegible] ounces of mixed peel, two ounces of sultanas, three quarters of a pint of milk, one lemon.

Method. Mix the yeast with a teaspoonful of castor sugar till both are liquid; warm the milk slightly and pour it into the yeast. Sieve the flour and a pinch of salt into a basin. Rub the butter lightly into it, then add the castor sugar, the cleaned sultanas, and the grated lemon rind. Mix these together, then beat and add the eggs, and lastly the yeast and milk. Mix all into a smooth dough, put it in a basin, cover it and put it at the side of the kitchen fire to rise for one and a half hours, or till the dough is twice its original size. Then turn it on to a floured board, work in the granulated sugar, keeping back a little to shake over each bun. Put small rough heaps of the mixture on a greased baking tin, sprinkle some granulated sugar on the top of each, put the buns in a warm place to rise for twenty minutes, then bake them in a quick oven for about the same length of time. Put them on a sieve to cool.

Chocolate Cake

INGREDIENTS. Half a pound of butter, a quarter of a pound of castor sugar, half a pound of good plain chocolate, four eggs, a tablespoonful of milk, three ounces of cornflour, two ounces of ground rice, a small teaspoonful of baking-powder, chocolate icing.

Method. Cream together the butter and sugar, then add the eggs one by one, beating each one well in. Grate the chocolate, then put it in a saucepan with the milk and melt it slowly over a gentle heat, and add it to the butter, etc. Sieve together the cornflower, ground rice, and baking powder, add these to the other ingredients. Pour the mixture into a small cake tin lined with three layers of greased paper and bake it in a moderate oven for about one hour. Watch it carefully as it so quickly burns. Leave it till cold, then coat it with chocolate icing and decorate it with crystallised violets, pistachio nuts, or chopped almonds.

For the icing, grate three ounces of good chocolate. Put it on a tin in the oven and let it darken slightly. Sieve half a pound of icing sugar. Put the chocolate in a pan with half a gill of water; let it get hot, then add the icing sugar and stir it with a wooden spoon till it is melted. It should coat the spoon smoothly, otherwise it is too thin. If so, add a little more sugar. Pour it in spoonfuls over the cake and decorate it prettily.

Sally Luns

INGREDIENTS. Three quarters of a pound of flour, half a teaspoonful of salt, one ounce of butter, half an ounce of compressed yeast, one egg, one and a half gills of milk, a quarter of a teaspoonful of castor sugar.

Method. Mix together the flour and salt, then rub in the butter. Cream the yeast and sugar together till they are liquid. Warm the milk till it is just tepid and mix it with the yeast. Beat up the egg and add it to the milk, then strain the milk, etc., into the middle of the flour, and mix it lightly in. Turn the paste on to a floured board, and knead lightly, using a little flour to prevent it sticking. Well grease two high round cake tins. Divide the dough in two, make each into a round cake, and drop it into the tin; twist a piece of greased paper over the tops and put them to rise till the dough fills the tins. Probably they will take one hour. When risen enough, bake in a quick oven about half an hour; turn them out and brush them over with a little warm milk and butter.

Shortbread

Ingredients. One pound of flour, half a pound of butter, four ounces of castor sugar, one egg.

Method. Put the butter into a large basin, work it with a wooden spoon or the hand till rather soft. Add the sugar and egg, mix together lightly, add the flour gradually, kneading it well. Shape into two or more round cakes according to the size required. Decorate the edges, prick the cakes well over with a fork. Bake very slowly till they are a very pale brown. Dust with sieved castor sugar, but do not move them till cold.

Plain Soda Cake

Ingredients. One pound of flour, six ounces of butter or dripping, six ounces of castor sugar, six ounces of sultanas, two ounces of candied peel, one teaspoonful of carbonate of soda, half a pint of milk, one egg.

Method. Line a cake tin with greased paper. Cream the sugar and butter till they look white and soft, then beat in the egg. Clean and stalk the sultanas, chop the peel, mix the flour and carbonate of soda, stir them lightly to the butter and sugar. Add the milk, mix well together. Put the mixture into a tin, bake it in a moderate oven for about two hours, or till a skewer pushed through the centre of the cake comes out quite clean.

Rice Buns

Ingredients. Half a pound of castor sugar, a quarter of a pound of butter, four ounces of flour, eight ounces of ground rice, one teaspoonful of baking-powder and two eggs.

Method. Mix together two extra teaspoonfuls of flour and the same amount of castor sugar Then grease some patty tins, put a little of the mixture of flour and sugar in each, shake it all over and turn out all that does not stick, leaving the tin thinly coated all over. Mix together the flour and ground rice. Cream together the butter and sugar, then add to them half the flour and rice and one egg. Mix well together, then put in the rest of the flour and rice (all but one teaspoonful) and the other egg, and, lastly, add the baking-powder with the teaspoonful of flour. Stir it all well together. Put the mixture into prepared patty tins, and bake in a moderate oven for from ten to fifteen minutes. When done turn the buns out and put them on a sieve till cold.

Almond and Chocolate Biscuits

Ingredients. Four ounces of ground sweet almonds, four ounces of castor sugar, two ounces of grated chocolate, one teaspoonful of powdered cinnamon, three whites of eggs.

Method. Mix the almonds with the castor sugar, the grated chocolate, and the powdered cinnamon. Mix and rub thoroughly together. Take the whites of the eggs, and beat them to a very stiff froth. Stir them lightly to the almond and chocolate mixture. If it seems to be getting very moist leave out some of the whites as it must be a stiff mixture. Line a flat baking tin with buttered paper, put little rough heaps of the mixture on it at a good distance apart, and bake very carefully in a slow oven till crisp. Take every precaution to see they do not burn.

BEVERAGES

Lemonade

Ingredients. Two or three lemons, two ounces of lump sugar, one quart of boiling water, a few lumps of ice.

Method. Peel the lemons very thinly, and carefully peel off all the pith, otherwise the lemonade will have a bitter flavour. Cut the lemon into thin slices, taking out all the pips, and then put the peel, slices of lemon, and sugar in a jug, and pour over them the boiling water. Cover the jug and let the lemonade stand till it is cold, then strain it into a glass jug, pressing the slices well. Before serving it, add a few thin slices of lemon and a few lumps of ice.

Lemon Squash

Ingredients. Small lumps of ice, the juice of one lemon, two teaspoonfuls of castor sugar, soda-water.

Method. Fill a tumbler half full with the lumps of ice, then strain on to it the juice of the lemon, add also the castor sugar. Then fill the glass up with soda-water, and mix all well together. This beverage is usually prepared at the table.

Iced Coffee

Ingredients. Four large tablespoonfuls of coffee, a few grains of salt, one quart of boiling water, three tablespoonfuls of castor sugar, half a pint of cold milk, half a pint of cream, ice.

Method. Put the coffee and salt into a jug, pour on to it a quart of boiling water. Cover the jug and place it at the side of the fire for ten minutes, then pour a few cupfuls of coffee backwards and forwards to clear it. Cover the jug again, and let it stand for ten minutes for the coffee grounds to settle. Then strain the coffee through a piece of fine muslin, add to it the sugar, milk, and cream, or, if more convenient, use all milk. Place the jug containing the coffee in ice for from four to six hours. Just before serving add two or three lumps of ice.

Claret Cup

Ingredients. One bottle of claret, two bottles of soda-water, two glasses of sherry, a quarter of a pound of castor sugar, one lemon, three strawberries, a sprig or two of borage, two or three inches of cucumber, half a pound of ice.

Method. Slice the lemon and remove the pips, also cut the cucumber into thin slices without peeling it. Put all the ingredients into a large glass jug and let them stand one hour. Remove the cucumber, borage and lemon, add the ice, and the claret cup is ready.

A Cup of Chocolate

INGREDIENTS. About one ounce of good chocolate to each breakfastcup of milk.

Method. Buy either cakes or powdered chocolate. Melt it in a cup with a tablespoonful of milk. Bring the milk to the boil, pour it on the chocolate, put it in a clean saucepan, and whisk it with a fork or small egg-whisk till it boils. Sweeten it to taste, then serve it at once with a teaspoonful of whipped cream on the top. If preferred less rich, add more milk.

Coffee

INGREDIENTS. Allow a good tablespoonful of coffee for each breakfastcupful wanted, boiling water, a pinch of salt.

Method. The following is a simple method. Put the coffee and a pinch of salt into a warmed jug, pour on it the boiling water; cover the jug and let it stand at the side of the fire for five minutes, then pour a cupful backwards and forwards four times. Cover it and let it settle. Pour it gently off into a warmed coffee-pot and serve with it hot milk. When possible, buy coffee berries and grind them at home. If that is impossible, buy at a shop where the coffee is freshly ground each day; this makes a great difference in the flavour. If the flavour of chicory is liked, add about two tablespoonfuls of it to each pound of the coffee.

Tea

INGREDIENTS. Allow, unless the party is a large one, a teaspoonful for each person, boiling water.

Method. Take care all stale leaves have been washed out of the pot; heat it with boiling water, then put in the tea and pour on *freshly-boiled* water. Let it stand for from three to four minutes. If the water has been boiling for some time the tea will lose its delicate flavour, and will taste flat. Cheap teas are bad economy, as a much larger quantity has to be used. If the party is a large one it is better to make it in two tea-pots.

Barley Water

INGREDIENTS. Two ounces of pearl barley, one lemon rind, one quart of boiling water, four lumps of sugar.

Method. Put the barley in a saucepan with half a pint of cold water, bring it to the boil, and boil it for a minute or two, then strain off the water. Put it back in the saucepan with the thinly-pared rind of the lemon, the sugar, and boiling water. Let it boil gently till the water is as thick as good cream. Then strain it off, and it is ready. It is invaluable in a sick-room.

VEGETARIAN COOKERY

Macaroni à l'Americaine

INGREDIENTS. Six ounces of ribbon macaroni, one ounce of flour, one ounce of butter, half a pint of tomato pulp, browned crumbs.

Method. Boil the macaroni till tender in plenty of fast-boiling salted water, then wash it under the cold-water tap. Melt the butter in a saucepan, add the flour smoothly, then the tomato pulp; stir it over the fire for a few minutes, then pass it through a sieve and season it carefully. Cut the macaroni into two-inch lengths, and add it to the sauce. Make it hot, turn it into a pie-dish, sprinkle the top with browned crumbs. Serve it with a border round the edge of the dish of nicely-fried sippets of bread.

Fricasseed Eggs

INGREDIENTS. One pint of milk, one large onion, two cloves, one carrot, a small bunch of parsley, four or more eggs, two ounces of butter, one and a half ounces of flour, a few slices of bacon.

Method. Put into the saucepan the milk, onion, cloves (stuck in the onion), carrot, and parsley. Let these simmer for half an hour. Boil the eggs for about twenty minutes till they are hard. Then shell them and cut them in half. Melt the butter in a pan, add the flour, and stir it in smoothly. Next strain in the milk, and stir over the fire till it boils and thickens. Season well with salt, pepper, and a few drops of lemon juice. Then put in the eggs. Let them get very hot in the sauce; take care in moving them that you do not knock out the yolks. While they are heating, cut some raw streaky bacon into neat dice, also some stale white bread. Fry both a pale brown. Chop finely two teaspoonfuls of parsley. Arrange the eggs on a hot dish; pour the sauce over them. Put little heaps of fried bread and bacon, or chopped parsley, alternately round the edge.

Tomato Pie

INGREDIENTS. Three-quarters of a pound of rough puff pastry, a quarter of a pound of macaroni, two teaspoonfuls of chopped parsley, one and a half pounds of tomatoes, one ounce of butter, three-quarters of an ounce of flour, two hard-boiled eggs, half a pint of water, salt and pepper.

Method. Break the macaroni into pieces about an inch long, throw them into a pan of fast-boiling water, and let them boil till they are tender, then drain off the water. Butter the inside of a pie-dish, put in a layer of sliced tomatoes, then a layer of cooked macaroni, next a good sprinkling of salt, pepper, chopped parsley, and onion, then another layer of tomatoes, and so on till the dish is full. Arrange the eggs, cut in slices, on the top. Melt the butter in a small saucepan, add the flour, and fry it a pale brown; next pour in half a pint of cold water, and stir it over the fire until it boils. Season it with salt and pepper. Pour the sauce into a pie-dish. Cover the dish with the pastry as you would an ordinary pie, and decorate it prettily with leaves and a tassel of pastry. Brush the top of the pie with beaten egg to glaze it, and bake it in a quick oven for about three-quarters of an hour.

Beetroot, Lentils, and Egg Sauce

INGREDIENTS. One pint of lentils, one quart of water, a bunch of parsley and herbs,. one large onion, two ounces of butter, one or two beetroots, egg sauce.

Method. Wash the lentils and put them to soak in water overnight. Next put them in a saucepan with the water, herbs, and onion, and let them boil for about one and a half hours,

or till they are soft. Then drain off the water, and rub the lentils through a sieve. Boil the beetroot till tender, taking care none of the little rootlets are broken or it will lose its colour. Melt the butter in a saucepan, stir in the lentils, and salt and pepper to taste; make it very hot, then pile it up on a hot dish. Pour some good egg sauce over it and arrange a border of slices of beetroot round. Almost any cooked vegetables may be used instead of beetroot.

KITCHEN ECONOMIES

We have much to learn from the French in the matter of economy. To them no scrap of food is too small to be of use, while the average English cook is given to despise them. Perhaps one of the chief items of waste is bread, which is allowed to get stale and is then thrown away. A careful cook can and will utilise every scrap of bread, and will do so without feeding the family on nothing but bread puddings, which to many people seems its one and only destiny. All crusts and scraps of bread should be collected, should be torn up small, put in a baking tin and dried slowly in the oven. They should then be pounded in a mortar, or, failing that, put between two pieces of paper and pounded with a flat iron. If possible, they should then be sieved, and kept in a tin till wanted. It is well to have some dried so slowly that they are not in the least coloured, and others coloured a pretty brown. The former are useful for coating rissoles, fish, fish cakes, and for making puddings of various kinds, while the latter are nice for "au gratin" dishes, and to give a touch of colour to various other dishes.

These crumbs will keep good for months in a tin, but on no account must the lid be put on till they are quite dry. Another use for stale bread is as a substitute for the more extravagant "pulled bread." Pull the bread into small rough pieces, put them on a baking tin and bake them in a moderate oven till they are a pretty golden brown. These are delicious with butter or cheese, or with soup instead of toasted or fried bread. Slices of stale bread or bread-and-butter make excellent fritters. They should be spread with a little jam, sandwiched together, dipped in frying batter, and then fried in hot fat till they are a golden brown.

There are also many excellent recipes for puddings and tarts in which crumbs form part of the ingredients.

Cooked potatoes are another frequent cause of waste. There is no excuse for even the smallest scrap to be thrown away. If the potatoes are whole, slice them, toss them with a little butter in a pan over the fire till they are hot through. Serve them in a hot dish sprinkled with a little chopped parsley.

If the potatoes are at all broken, they can be mashed, made hot with a little butter, milk, salt and pepper, and served as mashed potatoes; or they may be shaped into small balls, brushed over with egg, covered with crumbs and fried a golden brown in hot fat. They are then called potato croquettes.

They are also useful for making fish cakes, meat and potato cutlets, shepherd's pie, etc. Then, again, with a few tomatoes or beetroot and some salad dressing, they make a delicious salad.

The remains of any cold cooked vegetables can be served as a salad with the addition of salad dressing or mayonnaise sauce, while many vegetables can be reheated with butter—such, for example, as green peas or French beans. Many cold vegetables make a pretty garnish for soups or meat dishes—peas, asparagus, cauliflower. It might not be worth while to cook them on purpose to garnish a dish, but if already cooked they would prove a great addition.

There is a use for all scraps of meat. They may be chopped, heated in a pan with a little gravy or stock, seasoned nicely with chopped parsley, onion, salt and pepper, then either be put in a dish, covered over with mashed potato, nicely browned in the oven and served hot as rock pie, or be served on a hot dish garnished with neat sippets of toast as mince; or the mixture might be heaped up on neat squares of hot buttered toast and served as a breakfast or supper dish. Cold meat is also used for rissoles, croquettes, scallops, etc.

Cold fish could be mixed with any fish sauce there happened to be over, then served either in scallop shells with a few browned crumbs sprinkled over them, or in a pie-dish with a covering of mashed potato or boiled rice. Or it might be mixed with the sauce—its own weight in mashed potatoes and a good seasoning—then formed into round, flat cakes, egged, crumbed and fried.

The remains of curry make an excellent breakfast dish if chopped up finely, the meat, sauce and rice mixed all together, made thoroughly hot, and served on croûtons of fried bread, or, if preferred, slices of buttered toast.

It is well to bear in mind when using up cold meat that it will have lost some of its flavour and its nutritious matter, therefore special care should be given to its seasoning, and a little good stock or gravy should be added to it. Again, cooked meat should always be reheated gently; if it is allowed to boil it will become tough and tasteless. The meat to be warmed should be placed on the fire in warm water; if put in cold, all the goodness will be drawn out, and if in boiling water, the meat will be tough.

Plain boiled rice can be made savoury by the addition of a good-sized piece of butter, a little ketchup or Worcester sauce, and, if liked, two sliced tomatoes. This mixture should be served as hot as possible.

Stale pieces of cheese should be grated and stored in bottles; it is useful for macaroni cheese, cheese pudding, etc. Cold poached eggs seem to the unenlightened utterly worthless; but they may be reheated slowly in plain melted butter or parsley sauce, and served on fresh slices of buttered toast with a spoonful of the sauce.

All bones and trimmings of ham should be put in the stock-pot, and so become the foundation of soups and gravies.

All scraps of fat, cooked and uncooked, should be made into clarified fat. They should be cut into small pieces, put into a saucepan with a pint of water to each four pounds of fat, and allowed to cook till the pieces of fat are shrivelled up and the liquid fat is clear; it should then be strained off into jars, and can be used for pastry, plain cakes, and for frying purposes.

By the way, it is quite worth while periodically to purchase "pieces of fat" from the butcher to clarify; it costs usually about threepence a pound, although, of course, if large quantities of meat are consumed in the house there will probably be sufficient fat for this purpose.

Pieces of stale cake, grated or sliced, can be made into delicious puddings by adding some eggs and milk to them, allowing two eggs to a pint of milk. Put the mixture either into a pie-dish and bake it in the oven, or in a greased basin and steam it for from one to two hours.

Sour milk is excellent for scones; it may also be used for cleaning linoleum.

We give three dishes which may be made from scraps which would otherwise be thrown away as waste.

Miroton of Beef.

Ingredients. Two ounces of butter or dripping, four medium-sized onions, one small bunch of mixed herbs, salt and pepper, one tablespoonful of French vinegar, half a pint of good stock, thin slices of cold beef, a few brown breadcrumbs, and some cooked vegetables.

Method. Melt the dripping. Peel and slice the onions, add them to the dripping, and fry them a golden brown. Add the herbs and seasoning, the vinegar, stock, and a pinch of castor sugar. Let it boil for fifteen minutes, keeping it well skimmed: then strain it. Cut some thin slices of beef, cover the bottom of a pudding dish with some of the sauce, then put in a layer of beef, then more sauce, and so on. The last layer should be of sauce, on which a few browned crumbs should be sprinkled. Place the dish in a pan of boiling water, and put it in a hot oven for fifteen minutes. Serve it as hot as possible, and garnish it with nicely-cut cooked vegetables.

Timbales of Cold Meat.

Ingredients. Half a pound of any cold meat, two small tablespoonfuls of breadcrumbs, half a teaspoonful of chopped onion, two teaspoonfuls of chopped parsley, salt and pepper, a little milk, one egg.

Method. Thickly butter some small moulds and decorate them by pressing thinly-cut rings of cooked macaroni over the inside. The butter will hold any decoration in place. Chop the meat and mix it with the breadcrumbs, onion, parsley and seasoning and enough milk to make it rather moist. Beat up the egg and add it to the mixture, then fill the tins with it. Put them in a shallow saucepan with boiling water to come half way up them. Put a piece of greased paper over the top and steam them gently for an hour. Turn them out on a hot dish and pour some brown or tomato sauce over them.

Kedgeree.

Ingredients. One ounce of butter or dripping, half a pound of boiled rice, half a pound of any cold cooked fish, salt, pepper and cayenne, one or two hard-boiled eggs, a little mace, if liked.

Method. Melt the butter in a pan, add to it the rice, fish, and whites of the eggs cut into small pieces. Season it well and make it thoroughly hot. Pile it up on a hot dish and garnish it with some finely-chopped parsley and hard-boiled yolks of egg rubbed through a sieve.

WORKSHOP PRACTICE
continued from page 2114

By JOSEPH G. HORNER

IN the last article we selected cast objects of forms so plain that there was nothing to complicate the delivery of their patterns from the moulds. That is, there were no portions overhanging in the lower parts of the moulds, with overlying sand that could interfere with the ready withdrawal of the patterns. Everything was tapered downwards, and only one sand joint was required between the top and bottom portions of the moulds. But such simple examples only constitute a small portion of the moulder's work. So now we take up some illustrations of castings in which a good many problems not so simple are involved.

Flanged Castings. The figures from 20 to 25 show castings and methods which have resemblances and differences. In castings 20 and 23 there are flanges, one of which, if fast in the bottom of the mould, would prevent delivery of the pattern from the sand. In each there are central bosses; in each there are alternatives that are practical. We will dispose of the bosses first, because only a few remarks thereon are necessary.

The difference between those in 20 and 23 is that the space for sand left between the bosses and the inside edges of the rims is very small in 20, but ample in 23. It would be difficult to lift the sand out of the narrow zone in the former but easy to do so in the latter. The top portion of the boss in 20, therefore, must be attached loosely to the plate of the pattern 21, in this case with a central stud, to come into the sand of the top, and be withdrawn after turning over. But it is not necessary to do so in 24, although it is often done as shown, in order to avoid risks of a breakdown of the sand. Note may also be made of the large amount of *taper* given both to the bosses and to the internal portions of the rim in 21, with a view to easy delivery, though it happens also to coincide with the best form for strength.

Joints. With regard to the delivery of the lower flanges, it is necessary in 20 that the mould should part along *a—a*, so that the lower flange can be taken out after the removal of the top mould and pattern. In that case, the annular tread (*b*) must be fitted loosely in segments round the body of the pattern 21, to be left behind on the withdrawal of the latter, and to be pulled inwards subsequently in a horizontal direction. Or, leaving the projecting portion (*b*) loose might be avoided by jointing the pattern along the plane *c—c* [20]. In that case both flanges would have to be left loose, and sand joints made along the planes *a—a* and *d—d*. The only objection to this is the making of an extra sand joint.

The pattern 21 has its bottom flange (A) as a loose ring. The belt (*b*) is fitted in short lengths, and retained with skewers loosely. The method of building up shown is that adopted in work of this class, to which reference is made in the next section. The mould in 22 comprises now not only a top and bottom, but a *middle* part, requiring a moulding box in three corresponding sections.

Alternatives in Joints. In 23 the sand joints required are two, along the planes *a—a a—a*. To produce these the pattern [24] is differently jointed, either along *b—b*, through the middle, or along one face of the plated centre, one half of the sheave being then fitted as a ring, as shown. This may be a wooden pattern, in which case it is built in segments similarly to 21. Or, as is often done for repetitive work, an iron or brass pattern is made with wooden bosses, interchangeable by means of their central studs. This is the pattern shown by way of alternative in 24. Another alternative is to core the rim out, using an annular print; but that method is rarely adopted, except in the case of wheels that have recesses for chain, and not always then, cores being generally reserved for wheels of large diameter. The device is also employed when broken castings have to be moulded from, in which case a segmental print is rammed round the casting in the mould in successive positions until the circle of the print impression is completed.

Fig. 25 gives a section through the cored mould, with the two joints at *a—a*, leaving a middle ring of sand.

Three-part Joints. Fig. 26 illustrates a bevel wheel and a spur pinion cast together, and both *double-flanged*. Such an example cannot be drawn from the mould unless there are three joints in the sand, at *a*, *b*, and *c* respectively. It is a job for a *three-part* box, not four, as might be imagined, because the thickness from *a* to *b* is made in segmental cores, which involves less trouble than using a shallow moulding-box for the purpose of jointing. For convenience, the pattern in 27 is made with a greater number of joints than the mould, the object of which is to give perfect facilities for ramming, and also for ready delivery of the pattern parts, with the minimum of risk of tearing up the sand. The section of the pattern in 27, by comparison with the casting in 26 and the mould in 28, renders the nature of the work apparent. We have loose pieces again in the shroudings for the teeth, and in the separation of the pinion from the bevel wheel.

Cored Work. Fig. 29 is an example of a different kind from the foregoing, illustrating cored work in which the main core is completely enclosed within the body of the casting.

The roller in this figure is moulded, not as it runs, but flatwise, with its plane faces in top and bottom; not that it could not be moulded edgewise, but because the flat position renders the insertion of the cores easier. The pattern in 30 is built up in segments, the top and bottom sets (*aa*) covering the entire faces, the middle ones (*b*) being narrower and annular. The prints (*a*) will be noted as corresponding with the holes in 29. There is only one joint in the mould, that at *c*—*c* [31].

The main core for 29 is made in a box, rammed in core sand and dried. Generally, though not always, the shaft holes are made in cores distinct from the body core, as shown in the mould in 31. The small holes seen in the end plates in 29 and 31 are inserted simply to provide openings through which the core and core irons can be withdrawn after casting. When these are not inserted the work of the fettler is increased unnecessarily. In 31 the core is seen to be built round a skeleton of rings of iron rod.

Drum with Swept-up Core. The drum casting in 32 is moulded as it runs, with its cylindrical axis horizontally, differing in method, therefore, from 29. One reason for this difference is that the flanges on the drum may "lift" from the sand without being left loosely, while the roller [29] has no flanges, but a good coning, which makes the flat way of moulding the obvious one. The pattern is shown in 33, in half external view, and half section, *a*—*a* being its joint, corresponding with the mould joint. It affords an example of a method of construction termed *lagging up*, of which more later. The flanges, with boss, facings, and prints, are turned separately from the lagged body, and screwed on its ends.

Fig. 34 is a section through the mould. The core in 34 is swept on a bar—using "hay ropes" and loam—around skeleton core plates, the loam being in a plastic state, the whole mass being dried subsequently before insertion in the mould. When thus swept up, the cores for the shaft holes are swept up also on the bar, and the bar is stiff enough to sustain the weight of the core when laid horizontally in the mould. When a core is made in a box, as for 31, it is not so well able to sustain its weight as when a bar is used.

The engine crosshead in 35 may be moulded in the manner shown [38], or flatwise. The choice is so evenly balanced that crossheads are commonly made either way. The pattern with its prints is shown in 36, the core box in 37, and the finished mould in 38. Observations on the relations of the parts would be superfluous.

Engine Cylinders. These are more elaborated in the cores than in the moulds. Every different design of cylinder presents a distinct set of problems, which has to be tackled irrespective of other types. A comparatively plain example is given in cross-section only [39], being one for a particular type of steam crane. Fig. 40 is its pattern, 41 its mould; moulding as shown. Joints are made in the mould at *a*—*a*, *b*—*b*, and *c*—*c*; but only *a* and *c* coincide with the joints of the moulding box, the spaces between *b* and *a* being taken out by means of "false cores" or "drawbacks." There are thus six cores in this example [41], the main one (A) for the bore, the two false cores (B, B), two passage cores that do not come in this view, and one exhaust core (C), through which the sections are taken. The pattern for this [40] has to be jointed along *a*—*a* and *d*—*d*; while the feet over which the false cores are rammed are loosely attached to the cylinder body with screws, to be left behind in the mould until the false cores are lifted, after the delivery of the corresponding half of the pattern body, to which they are attached loosely.

Methods of Delivery. These examples afford a good selection of typical cases of moulding, and we shall occupy some space with further elucidation of some important matters that have been only touched on in passing. We have spoken of the necessity for making provision for getting patterns out of their moulds. This involves not only the jointings shown, but the fitting of loose pieces, and of drawbacks.

Loose Pieces. It is obvious that the mere vertical direction of withdrawal does not cover the case of patterns having portions standing out perpendicularly to those faces, or at angles therewith. Several examples of this kind occur in the figures preceding, in which *loose pieces* are fitted. This term signifies that pieces which cannot be drawn out with the main portion of the pattern without tearing up the sand mould that overlies them are attached loosely, being left behind to be withdrawn subsequently to the main portion. These loose pieces are fitted in many ways, by *skewers*, or *wires*, or loose nails—*i.e.*, nails that are not driven entirely in, but partly only, and so hold temporarily, and also by dovetails. The one essential is that the loose pieces shall be maintained in their exact location during ramming, which is the function of the skewers, nails, or dovetails. The moulder has to withdraw skewers or nails, when sufficient sand has been rammed round the loose pieces, to secure them in relation to the main pattern, but dovetails free themselves in the act of lifting.

Often loose pieces are held temporarily with dowels. A common lathe-bed, shown in section [42], will, with previous examples, illustrate typical methods of this kind.

A lathe-bed of the section in 42 may be made to mould in three ways equally well, as shown in 43 to 45, which give sections through the patterns. In 43 the bed faces are doweled on the bottoms of the ribs, in 44 they are wired at the sides, in 45 the outer pieces are wired, and the interior cored out, for which a print is provided.

A *drawback* [41*bb*]—the *false core* of the brass-founder—is a little mould within a mould, and fulfils a similar function to the loose pieces—that is, it carries sand that overlies projecting portions of patterns. It is adopted as an alternative, but is also more generally employed when loose pieces would not be suitable, on account of the great width of overhang.

Rapping. The *delivery* of patterns, as their withdrawal from the sand is termed, is accomplished by the assistance of *rapping*, for the purpose of loosening the pattern from its surrounding sand. It is effected by inserting a pointed iron bar in the top of the pattern, or in a hole in a special form of plate attached to the pattern, and then striking the bar in lateral directions. The pattern being thus *loosened*, is *lifted* with a screw, and during the process rapping is continued with a wooden mallet on the pattern face to detach it more effectually from the sand.

A result of rapping is that the mould becomes slightly enlarged, and in the hands of careless moulders this often results in inaccurate castings and in badly broken moulds. It is in this work of withdrawal that the moulding machines give superior results to handwork, because the lift is absolutely perpendicular, and the rapping required is nearly nil; or it is often avoided altogether by drawing the pattern through a plate, having a hole cut to the same outlines as that of the pattern, and which holds the sand down, hence termed a *stripping plate*.

Taper. We have said little yet about an important matter to which slight allusion has been made, though it is illustrated in nearly every preceding drawing—that of *taper*, *draught*, or *strip*, as it is variously called.

The way in which taper assists the delivery of a pattern is clear from **46**, in which the withdrawal of a quite parallel piece is contrasted with that of a tapered piece.

The parallel piece A, though drawn halfway out of the mould, as at B, is still as tightly confined by the sand as at first. The tapered piece C, on the contrary, similarly withdrawn, D, is entirely clear of the sand, and requires no effort to withdraw it through the remainder of the way. In B the sand will assuredly become fractured along the course of the dotted lines; while at D no fracture worth mentioning, probably none at all, will occur.

Even though there is taper in a pattern, the pressure and friction of the sand against the deep faces is so great that they could not be withdrawn without fracture of the sand unless the patterns were slightly loosened first by shaking or rapping them.

Amount of Taper. With regard to the amount of taper required no rules can be given. It is a matter for judgment, to be decided in the case of each individual piece of work. Still, some idea can be given of its amount.

If a rib like **46** be 1 ft. deep, the taper will usually range from $\frac{1}{16}$ in. to $\frac{1}{8}$ in. That is, the wood will be from $\frac{1}{16}$ in. to $\frac{1}{8}$ in. thinner at bottom than at top. If a rib were 2 ft. deep, the taper would range from $\frac{1}{8}$ in. to $\frac{1}{4}$ in. If 6 in. deep only, from $\frac{1}{32}$ in. to $\frac{1}{16}$ in. would be given. If 3 in. deep, $\frac{1}{64}$ in. would suffice; if 1 in. deep, the removal of a mere shaving would be sufficient.

Again, take the case of a loose rib which has to be withdrawn, as A in **47**, into the space B of the mould, with the pricker C held in a diagonal direction. In such cases taper much in excess of that given to vertical ribs is imparted, because the withdrawal is an awkward task, and if the sand breaks at the dotted line, as it is likely to do, it is difficult and troublesome to mend it up.

When the top portion of the sand of a mould has to be lifted off a pattern, the amount of taper required is greater than when the pattern is lifted from the sand.

Cores. The formation of hollow spaces is the function of "cores," using the term in its broadest sense. Parenthetically, we may note that the term *core* strictly relates to something made apart from the mould, and inserted subsequently. It is usually dried, but not invariably; if not, it is often termed a *green sand core*. If a piece that fulfils the function of a core be rammed in the mould, it is termed a false core, or *drawback*.

The methods of making cores are broadly divisible under three heads. Since any internal body of sand, as distinguished from external portions, is a core, the first method is that in which internal portions are delivered from the pattern, or self-delivery. But in the greater number of cases the core is rammed in a box separate and distinct from the pattern. The box encloses its sand, and, therefore, as in patterns, provision must be made for the removal of the core from its box without sustaining damage. Hence most boxes are divided in one or more planes, and the same devices of taper and loose pieces must be embodied in many boxes, as in patterns when identical conditions of delivery arise. Examples of boxes are given in **37** and **52**.

Loam Cores. The third great class of cores comprises that in which sweeping up in wet loam is adopted, as in **34**. It is applicable to heavy circular work, and to *strickled* work. The object often is to save the expense of making a large core box, but there are many cases in massive work in which a core rammed in sand would not be practicable. The loam is plastic, and is swept on a skeleton built upon a revolving core bar, and afterwards dried. In strickled work loam is still swept around a skeleton-like framing, but instead of a revolving bar, a guide iron, or the edge of a core plate becomes the guide to the movements of the strickle.

Core Prints. As a core has to be made separately from its mould, it is usually necessary to make provision to ensure its exact setting in the mould. This is the function of *core prints*, the forms of which are varied to suit the direction in which the core has to be inserted, its mass, or area, and other conditions. Core prints are put in top and bottom of patterns and moulds, or at the sides. In the latter position they often take the form of *pocket*, or *drop prints*, to avoid having to make a sand joint down to the centre of the print. Then the upper part of the drop print is filled up with sand after the insertion of the core, or the core box is made of such a shape that the core shall fill it up, or *stop itself off*. Numerous examples of cores set vertically are given in the preceding figures of core prints, but some further remarks are desirable relating to those in the

Drop Prints. Take the case of the lagged-up cylinder pattern, shown in section 48, with holes to be cored through the bolt bosses (A A) skewered on the inside of the foot, the drop prints being shown at B B. Looking at a section through one-half of the mould [49], a core (B) is made, and dropped into the mould. This core cannot be made of the full length (*a*) over print and boss, and dropped down into the mould through the narrower width (*b*). To put a pocket print on the same side as the boss would give trouble, which is avoided by making the prints B B [48] sufficiently thick to more than counterbalance the weight of their cores. Then, making the core B only of the length *b* in 49, it is dropped down into position, and then slid along to touch the face of the boss, as shown, afterwards filling up the space *c* with sand to keep it from shifting.

Not infrequently it happens that two or more holes are required horizontally in a plate, one above another, as in 50, which represents a pattern in side and end elevation, with the pocket prints for coring out the holes, the positions for which in the casting are indicated by dotted lines at *a a*. In such cases the prints are either superimposed (A B) or a single print is used, as in 51, and a special core box made.

When two prints superimposed are used the outer one should be made a little thicker than the one which goes next the pattern, to afford sufficient guidance for the top core, which has to pass across a greater distance than the bottom core. This is indicated in 50.

Fig. 52 shows a core box in plan, and opened in the joint face, for coring both holes with a single print.

Distinction Between Cores and Bosses. A natural question is, how is the moulder able to distinguish these core prints, which are not parts to be cast, from bosses, which have to be? Mistakes have often occurred in this way. Thus, a moulder not recognising the function of a roller in the pattern of 16, might cast the prints *a* on if a core box were not sent him. He could not make such an error in 36, having a core box, 37. Frequently in large patterns, bosses and prints are numerous and look alike, and it is not usual to send boxes for plain cores. Error is prevented in shops where a good system exists by varnishing or painting prints differently from the body of the pattern. Generally, clear yellow shellac varnish is used for the patterns, and black for the core prints. This is often carried a stage further. Patterns for brass are distinguished from those for iron by varnishing the bodies black and the prints yellow.

It is often necessary to make moulds with certain portions lowermost, to ensure sound, clean metal in surfaces which have to be planed, or otherwise machined bright. Such faces are painted red, or other distinctive colour. The lathe-bed [42] is a case in point. These are always cast upside down, as indicated in 43 to 45. Here the loose pieces render the method obvious. But often there is no distinctive feature of this kind to guide the moulder, hence the advantage of colouring red.

Shrinkage. One other matter calls for consideration here. All the common metals and alloys shrink as they cool down from the molten state. Unless the mould were made larger than the required dimensions of the casting when cold, the latter would be too small. So that all patterns are made of larger dimensions than their castings by this amount, and this, again, varies in quantity in iron, steel, brass, gun-metal, aluminium, and not only in the different metals, but in metal of the same name in different compositions, and under diverse conditions of casting.

The following table embodies averages for the common metals and alloys:

SHRINKAGES OF CASTINGS.

Cast iron, average $\frac{1}{8}$ in. in 15 in.; light castings, $\frac{1}{8}$ in. in 16 in.; heavy and mottled, $\frac{1}{8}$ in. per 12 in.; work mainly cored, $\frac{1}{8}$ in. per 12 in., or less.

Malleable cast iron, $\frac{3}{16}$. in to $\frac{1}{4}$ in. per 12 in.

Bronzes and brasses, $\frac{1}{8}$ in. to $\frac{1}{4}$ in. per 12 in., depending on composition and on mass.

Steels, $\frac{1}{8}$ in. to $\frac{1}{4}$ in. in 12 in. Heavy castings shrink most, light ones least.

Aluminium, $\frac{1}{4}$ in. in 12 in.

Copper, $\frac{3}{16}$ in. in 12 in.

Lead, $\frac{3}{16}$ in. to $\frac{5}{16}$ in. in 12 in., depending on its degree of purity.

Tin, $\frac{1}{8}$ in. in 12 in.

Patterns for Different Metals. A question that arises not infrequently in most shops is this: Castings are wanted off the same patterns at different times in iron and in steel; and in the smaller pinions, also in gun-metal or phosphor-bronze. As the shrinkage of these varies, the foreman who has to give orders for each in turn has to attempt to reconcile the irreconcilable. The difficulties have to be got over by these methods.

For standard work, where correct pitch diameters must be maintained, separate patterns must be made for cast iron and steel. But the latter will serve also for gun-metal and phosphor-bronze. In very small pinions not exceeding, say, 6 in. in diameter, the difference in shrinkage may be neglected, but over that size it becomes very marked. In fact, a heavy, solid pinion of 10 or 12 in. diameter will show a higher rate of shrinkage than a larger wheel with arms. For large steel wheels the moulding-machine offers advantages over pattern-moulded gears, especially when gears are shrouded.

An advantage of making a separate pattern, or a special set of pattern parts for machine moulding for steel, is that the sections can be lessened, steel being stronger than iron.

When exact centres are not important, then these steel wheels can be cast from patterns made for iron, and though the difference in diameter may amount to several eighths of an inch in a wheel of fair size, yet the pitch will be practically unaffected.

NOUNS

Formation of the Plural. (1) Nouns ending with an unaccented vowel take an *s* in the plural, thus:

SINGULAR.	PLURAL.
carta, letter	*cartas*
madre, mother	*madres*
libro, book	*libros*
espiritu, spirit	*espiritus*

(2) Nouns ending in *é* also take *s* in the plural:

pié, foot	*piés*
café, coffee	*cafés*
té, tea	*tés*

(3) Nouns ending in an accented vowel take *es* in the plural:

bajá, pasha	*bajáes*
rubí, ruby	*rubíes*
tisú, tissue	*tisúes*

Exceptions to this rule are *papa*, *mama*, *sofa*, which take *s* only; pl., *papas*, *mamas*, *sofas*.

(4) Nouns ending in a consonant also take *es* in the plural:

verdad, truth	*verdades*
dolor, grief	*dolores*
razon, reason	*razones*
rey, king	*reyes*

(5) Nouns ending in *z* convert *z* into *ces* in the plural:

voz, voice	*voces*
juez, judge	*jueces*
pez, fish	*peces*

(6) Polysyllabic words unaccented on the last syllable, and surnames ending in *s* and *z* are invariable in the plural:

lunes, Monday	*los lunes*
crisis, crisis	*las crisis*
Valdés (a surname)	*los Valdés*
Fernandez (a surname)	*los Fernandez*

(7) Some Spanish plurals may include the feminine, ex.:

los reyes, the kings, or the king and queen.

los amos, the masters, or the master and mistress.

los abuelos, the grandfathers, or the grandparents.

los padres, the fathers, or the parents.

Genders. The gender of nouns is determined by their signification or termination.

As a general rule the ending *a* denotes the feminine gender, and *o* the masculine, as: *el macho*, the male; *la hembra*, the female.

The following nouns are masculine by signification:

(1) All names of men or male animals and of dignities, professions, and callings peculiar to men.

soldado, soldier
cura, curate
albañil, mason
toro, bull
perro, dog
caballo, horse

(2) The names of countries, cities, and towns are generally masculine, except those ending in *a*.

(3) All rivers are masculine except the Huerva, which is feminine, and the Esqueva, to which both genders are applied.

The following nouns are feminine by signification:

(1) All names of women or female animals and of dignities, professions, and employments usually assigned to women:

lavandera, washerwoman
cocinera, cook
costurera, seamstress
vaca, cow
gallina, hen
yegua, mare

(2) The names of arts and sciences, except those ending in *o*, as: *la escultura*, sculpture; *la geometria*, geometry.

(3) The names of virtues, as: *la fé*, faith; *la constancia*, constancy.

Masculine by termination: Nearly all nouns ending in *e*, *i*, *o*, *u*, *j*, *l*, *n*, *r*, *s*, *t*.

Feminine by termination: Nearly all nouns ending in *a*, *d*, *z*, *is*, *en*, *ion*, *ente*, *be*, *re*, *bre*, *erte*.

The exceptions to these general rules can only be learnt by practice.

Some nouns are used in both genders, as: *mar*, the sea, which is either masculine or feminine; but all its derivatives are feminine; as: *la bajamar*, low tide; *la pleamar*, high tide. *Arte*, art, is always feminine in the plural and sometimes masculine in the singular, as: *las bellas artes*, the fine arts; *el arte dramático*, dramatic art.

Some nouns have a different meaning, according to their gender:

el cometa, comet	*la cometa*, child's kite
el corte, cut	*la corte*, court
el moral, mulberry tree	*la moral*, morals
el cólera, cholera	*la cólera*, anger
el papa, pope	*la papa*, potato
el pendiente, pendant	*la pendiente*, slope
el pez, fish	*la pez*, pitch

Formation of the Feminine. Most masculine nouns may be made feminine as follows:

By changing final *o* or *e* into *a*, as: *hermano*, brother; *hermana*, sister; *monje*, monk; *monja*, nun.

By adding *a* to the masculine, as: *marques*, marquis; *marquesa*, marchioness.

A few nouns ending in *or* change their ending to *triz* in the feminine, as: *actor*, actor; *actriz*, actress; *emperador*, emperor; *emperatriz*, empress.

Some form the feminine by adding *esa* to the masculine, as: *abad*, abbot; *abadesa*, abbess; *conde*, count; *condesa*, countess.

A few change their termination into *isa*, as: *poeta*, poet; *poetisa*, poetess; *profeta*, prophet; *profetisa*, prophetess; *diácono*, deacon; *diaconisa*, deaconess.

Vocabulary Vocabulario

The head	La cabeza	To walk	Andar

and the lawyer defends it. 23. The magistrate
. . . . lo defiende . . . .
administers justice. 24. To plead is costly.
administra . . . . costoso.
25. One can appeal when one loses a law-suit.
. . Se puede . . . cuando se pierde . . . . . .

Note. For the verbs eating, touching, etc., use the infinitive.

PROSE EXTRACT III.

From the "Historia General de España," by Juan de Mariana.

THE DEATH OF KING RODERICK.	LA MUERTE DEL REY DON RODRIGO.
The Goths advanced to the sound of their drums and trumpets; the Moors beat to battle with their metal kettledrums, according to their fashion. Loud was the clamour on both sides, until the mountains and valleys seemed to meet.	Los godos al son de sus trompetas y cajas se adelantaron, los moros al son de los atabales de metal á su manera encendian la pelea; fue grande la gritería de la una parte y de la otra; parecia hundirse montes y valles.
At first they fought with slings, darts, all sorts of arrows, and lances; then they began with swords. The battle was very fierce, for one side fought as conquerors, and the other as determined to conquer.	Primero con hondas, dardos y todo genero de saetas y lanzas se comenzó la pelea; despues vinieron á las espadas; la pelea fué muy brava porque los unos peleában como vencedores; y los otros por vencer.
The victory was doubtful for the best part of the day, though the Moors gave signs of yielding and seemed disposed to slacken, and even to retreat. Then—oh, incredible wickedness!—Don Oppas, who had hitherto concealed his treason, suddenly went over to the enemy with a good number of his followers in the greatest heat of the battle, as he had planned in secret.	La victoria estuvo dudosa hasta gran parte del dia sin declararse; solo los moros daban alguna muestra de flaqueza, y parecia querian ciar y aun volver las espaldas, cuando Don Oppas! oh incredible maldad! disimulada harta entonces la traicion, en lo mas recio de la pelea, segun que de secreto lo tenia concertado, con un buen golpe de los suyos se pasó á los enemigos.
He joined Don Julian, who was followed by a great number of Goths, and together they attacked our weakest flank. Our men, astounded at such treachery, and tired out with fighting, could not endure this fresh attack, and were easily broken and put to flight, though the king with his most valiant followers fought in the van, helping in every direction, succouring those who were in danger, replacing the dead and wounded with fresh men, and even arresting the fugitives with his own hands. Thus he played the part both of a good captain and a brave soldier.	Juntosé con don Julian, que tenia consigo gran número de los godos, y de través por el costado mas flaco acometió á los nuestros. Ellos, atónitos con traicion tan grande y por estar cansados de pelear, no pudieron sufrir aquel nuevo impetu, y sin dificultad fueron rotos y puestos en huida, no obstante que el rey con los mas esforzados peleaba entre los primeros y acudia á todas partes, socorria á los que veia en peligro, en lugar de los heridos y muertos ponia otros sanos, detenia a los que huian a veces con su misma mano; de suerte que no solo hacía las partes de un buen capitan, sino tambien de valeroso soldado.
At last, all hope of victory being lost, to escape falling alive into the hands of the enemy, he leapt from his chariot, mounted a horse called *Orelia*, which he had with him in case of such emergency, and withdrew from the field.	Pero al último, perdida la esperanza de vencer, y por no venir vivo en poder de los enemigos, saltó del carro y subió en un caballo llamado Orelia, que llevaba de respeto para lo que pudiese suceder; con tanto él se salió de la batalla.
Bereft of his help, the Goths, who were still fighting, lost heart; some were left dead on the field, the rest took to flight, and the tents and baggage were taken in a moment.	Los godos que todavía continuaban la pelea, quitada esta ayuda, se desanimaron, parte quedaron en el campo muertos, los demas se pusieron en huida; los reales y el bagaje en un momento fueron tomados.
The number of the dead is not stated, I suppose because they were so many that they could not be counted, for, verily, by this battle alone Spain was despoiled of all her courage and glory. Fatal day—day of tears and sorrow! There fell the glorious name of the Goths, their martial might, their fame of ancient times! There ended the hope of posterity, and the empire which had endured for more than three hundred years was overthrown by a fierce and cruel nation.	El numero de los muertos no se dice; entiendo yo que por ser tantos no se pudieron contar; que a la verdad esta sola batalla despojó á España de todo su arreo y valor. Dia aciago, jornada triste y llorosa. Alli perecció el nombre ínclito de los godos, alli el esfuerzo militar, alli la fama del tiempo pasada, alli la esperanza del venidero se acabaron, y el imperio que mas de trescientos años habia durado quedó abatido por esta gente feroz y cruel.
Don Roderick's horse, his surcoat, crown, and buskins, embroidered in pearls and jewels, were found on the bank of the river Guadalete, and as no other trace of him was	El caballo del rey don Rodrigo, su sobreveste, corona y calzado, sembrado de perlas y pedreria, fueron hallados á la ribera del rio Guadalete, y como quier que no se hall.

found it was supposed that he was killed in his flight, or was drowned in crossing the river.	**asen algunos otros rastros de él se entiende que en la huida murió ó se ahogó á la pasada del rio.**
It is true that 200 years later a stone was found in a church in the city of Viseo, in Portugal, with a Latin inscription, which, translated into the Romance language, is as follows:	**Verdad es que como doscientos años adelante en cierto templo de Portugal, en la cuidad de Viseo se halló una piedra con un letrero en latin, que vuelto en romance dice:**
Here lies Roderick, the last king of the Goths.	*Aqui reposa Rodrigo, ultimo rey de los Godos.*
From this it is supposed that after the battle he fled to Portugal.	Por donde se entiende que salido de la batalla, huyó á las partes de Portugal.
Juan de Mariana (1536-1623) is the most celebrated historian of Spain. His "Historia General de España" was the first general history of that country ever written. It begins with the supposed peopling of Spain by Tubal, son of Japhet, and comes down to the **accession of Charles V. The fame of Mariana rests rather on the beauty of his prose than on his historical accuracy.**	Juan de Mariana (1536-1623) el mas célebre historiador de España. Su "Historia general de España" fué la primera que se escribió. Empieza con la supuesta problacion de España por Tubal, hijo de Japhet, hasta la ascencion de Carlos V. La fama de Mari**ana resta mas en la belleza de su prosa, que en su exactitud historica.**

KEY TO EXERCISE II.

1. **El oro y la plata son considerados como los más preciosos metales.**
2. **Las minas de cobre son á veces de más provecho que las de oro y plata.**
3. **El fuego como elemento es devastador.**
4. El aire es fresco.
5. La lluvia aplaca el viento.
6. La noche es para descansar.
7. El dia es para trabajar.
8. Pescamos en el río.
9. En el jardin hay flores.
10. En el huerto hay frutas.
11. Las flores del campo son artisticas.
12. *El* mar del Norte es tempestuoso.
13. *La* mar es plácida.
14. *El* alma es inmortal.
15. *Las* almas de los justos descansan en el Señor.
16. *El* hada benéfica.
17. *Las* hadas malévolas.
18. Enterrar *el* hacha es señal de paz entre los indios.
19. Se usaban *las* hachas como armas de defensa.
20. Echar *el* ancla.
21. *Las* anclas de los navíos.

PLURAL OF NOUNS

General Rule. (*a*) All masculine nouns ending either in *o* or *a*, and all masculine, feminine, and common gender nouns ending in *e* (not preceded by an *i*), form the plural by changing the *o*, *a*, *e* into *i*. Thus: *il quadro* (the picture), *i quadri*; *il poeta* (the poet), *i poeti*; *il lume* (the lamp), *i lumi*; *la lezione* (the lesson), *le lezioni*; *l'abitante* (the inhabitant), *gli abitanti*; *il parente*, *i parenti*, etc. The feminine *mano* (hand) makes its plural regularly: *le mani*.

(*b*) All feminine nouns in *a* form the plural by changing the *a* into *e*, as: *la chiesa* (the church), *le chiese*; *la casa*, *le case*; *la carrozza*, *le carrozze*.

(*c*) All nouns ending in *i*, *ie*, except *moglie* (wife), *mogli*; all those ending in an accented vowel, monosyllabic nouns, and the very few ending in a *consonant* do not change in the plural. Ex.: *Il brindisi*, *i brindisi*; *la specie* (species, kind), *le specie*; *la città*, *le città*; *la povertà* (poverty), *le povertà*; *la servitù* (servitude, the servants), *le servitù*; *il re*, *i re*; *il lapis* (pencil), *i lapis*.

Compound Nouns. The compound nouns usually follow the general rule given above, as *passatempo* (pastime), *passatempi*; *mezzogiorno* (midday), *mezzogiorni*; *madreperla* (mother-of-pearl), *medreperle*; *lavamano* (washstand), *lavamani*. Observe, however, that:

(*a*) Some change both parts in the plural—*e.g.*, *capoluogo* (principal place), *capiluoghi*; *capocomico* (leading actor), *capicomici*; *bonamano* (gratuity), *bonemane*, etc.

(*b*) Some change the first part only—*e.g.*, *capofàbbrica* (manager), *capifabbrica*; *capocaccia* (chief huntsman), *capicaccia*, etc.

(*c*) Some have the same form in the singular and in the plural, as: *il salvagente* (life saver), *i salvagente*; *il portabandiera* (the standard bearer), *i portabandiera*, etc.

The plural of such nouns will always be given.

Vocabulary

nostro, our	*flotta*, fleet
vostro, your	*sordomuto*, deaf and dumb
àbito, coat, dress	*indirizzo*, address
sporco (fem. pl. *sporche*), dirty	*cavatappi*, corkscrew
settimana, week	*raccolto*, gathered, collected
ogni, every	*andare*, to go
terremoto, earthquake	*andato*, gone
tetto, roof, house	*danneggiato*, damaged
bottiglia, bottle	*dato*, given
ufficiale, officer	*aperto*, opened
pranzo, dinner	*perchè*, why, because

EXERCISE IX.

Nel nostro giardino abbiamo frutti e fiori. I ragazzi hanno raccolto dei fiori per i forestieri e hanno avuto del danaro. Gli abiti delle signore sono nel guardaroba. Le vostre mani sono sporche. I lavoratori avranno la paga ogni settimana. I lumi sono su la tavola. Nelle scuole, nelle chiese nei teatri hanno raccolto danari per i danneggiati dal terremoto. Gli abitanti sono senza (without) tetto. I soldati ebbero ordine di andare nelle città danneggiate. Vi sono molte vittime. Gli scolari avranno carta, lapis e penne. Gli ufficiali hanno dato un pranzo in onore della flotta inglese; vi sono stati molti brindisi. Hanno aperto una scuola per i sordomuti. Abbiamo molte bottiglie di vino, ma non abbiamo un cavatappi. Non abbiamo scritto le lettere, perchè non abbiamo trovato gl'indirizzi. Quando avrete scritto le risposte sarete liberi (free) di andare.

CONVERSAZIONE.

Ragazze, dove siete state domenica ?

Siamo state al giardino zoologico, dove abbiamo veduto (seen) leoni, leonesse, tigri, lupi e molti altri (many other) animali.

Dove avete raccolto tanti (so many) fiori ?

Nel giardino di nostra zia ; essi sono per le mogli degli ufficiali.

Perchè non siete andate a teatro ?

Perchè quando abbiamo ricevuto i biglietti (tickets) era già molto tardi (very late).

Quando saranno a Parigi i vostri amici ?

Essi saranno a Parigi domenica e saranno a Londra la settimana prossima (next).

Chi (who) ha comprato questi (these) portasigari ?

Il padrone ha comprato due (two) portasigari e un portabiglietti per i servitori.

Vi sono lettere per me ?

No, signore ; ma vi sono due telegrammi per la signora. La signora è andata all' esposizione con le sorelle e le nipoti del signor Dottore e sarà in casa alle due e mezzo (at half past two).

IRREGULARITIES IN THE PLURAL OF NOUNS.

1. *Uomo*, man, *uòmini*, men (*cf.* the Latin *homo, homines*) ; *ala* (fem.), wing, *ali*, wings—but : *le ale d'un esercito ; dio*, god, *dei*, gods ; *bue*, ox, *buoi*, oxen ; *mille* (*meèlleh*), thousand, *mila*, thousands.

2. The following words in the plural end in *a*, and become feminine :

Centinaio (*chehntee-nàh-eeo*), a hundred, *le centinaia ; migliaio* (*mee-lee-àh-eeo*), a thousand, *le migliaia ; miglio* (*meè-lee-o*), mile, *le miglia ; paio* (*pàh-eeo*) pair, *le paia ; uovo* (*oo-òvo*) egg, *le uova, le ova ; riso* (*reèso*), laughter, *le risa*.

3. *Brio* (*breèo*), vivacity, and *la prole* (*pròleh*), offspring, are used in the singular only.

Le esequie (*ehsèh-koo-ee-eh*), funeral, *le forbici* (*fòrbee-chee*), scissors, *le nozze* (*nòtseh*), wedding, *gli occhiali* (*ockee-àhlee*), spectacles, and a very few more nouns, are used in the plural only.

4. Some nouns change their signification in the plural, as : *genitore* (father), *genitori* (parents) ; *gente* (*dgènteh*), people, *genti* (men, nations) ; *misura* (*meesoòrah*), measure, *misure* (dispositions, also measures) ; *gràzia* (*gràtseeah*), grace, *grazie* (thanks, also graces).

5. Some words in *o* have a double plural, often with different meanings.

The commonest are :

Bràccio (arm), *le braccia* (of the human body) ; *i bracci* (figuratively) as : *i bracci della sedia* (the arms of the chair).

Dito (finger), *le dita* (speaking of all the fingers), as : *le dita della mano ; i diti* (specifying the fingers), as : *i diti mignoli* (the little fingers).

Frutto (fruit), *le frutta* (dessert) ; *i frutti* (income, profit), as : *i frutti dello studio* (study) ; *i frutti del capitale*.

Labbro (lip), *le labbra* (speaking of the human body) ; *i labbri* (figuratively), as : *i labbri d'una ferita* (wound).

Legno (wood), *le legna* (firewood) ; *i legni* (wood, ships).

Membro (limb), *le membra* (of the body and figuratively) ; *i membri* (figuratively, members of a society), as : *i membri del Parlamento*.

Muro (wall), *le mura* (speaking of a fortress, or of the walls of a city, or of a house as a whole) ; *i muri* (walls in general).

Osso (bone), *le ossa* (of the body) ; *gli ossi* (bones in general).

Pronounced : *bràcchee-o, deèto, froòtto, làhbbro, lèhneeo, mèhmbro, moòro, osso.*

Vocabulary

destra (*dèh-strah*), right

sinistra (*see-neè-strah*), left

freddo (*frèhddo*), cold

caldo (*kàhldo*), hot

brivido (*breè-veedo*), chill

carro (*cahrro*), waggon, cart

morte (*mòrteh*), death

aver freddo, to be cold

aver fame, to be hungry

pane (*pàhneh*), bread

argento (*ahr-dgèhn-to*), silver

dieci (*dee-èh-chee*), ten

parècchie (*pahrèh-kee-eh*), several

comprato, bought

portato, brought

là, lì (*lah, lee*), there

aver caldo, to be warm

aver sete, to be thirsty

EXERCISE X.

1. La mano ha cinque dita. 2. Le risa dei ragazzi. 3. Un carro tirato (drawn) da due paia di buoi. 4. Le due ale di destra dell'esèrcito nemico erano ciascuna di dieci mila uòmini. 5. Questa sera aviemo freddo, perchè non abbiamo legna in casa. 6. Abbiamo comprato delle uova e del pane perchè abbiamo fame. 7 Ho molto freddo ; ho i brividi nelle ossa. 8. Dove sono le fòrbici ? Sono lì, sulla tàvola, insieme con gli occhiali. 9. I contadini hanno portato frutti e fiori per le nozze d'argento dei padroni. 10. Alla morte della zia, quella ragazza avrà parècchie migliàia l'anno.

KEY TO EXERCISE VII.

The King and the Queen are at Windsor. The Emperor and the Empress of Russia will go to France [in] the month of August. The wife of the guard is a hard working woman. The Alpinists and the guides have lost themselves in the Alps. The ox, the cow, the she-goat, the hen are animals useful to man. The lioness and the tigress are more ferocious than the lion and the tiger. Louis's sister has two children, a boy and a girl. The grape and the date are the fruit of the vine and the palm-tree. The brother and niece of the baroness have the intention of going to Paris. A multitude of boys and girls are in the country with the mistress and the landlady. The son-in-law of the doctor is an artist and the sister is a pianist. The daughter of the physician is a doctor of literature and also a poetess and a painter; she is authoress of a poem and [painter] of a picture, which is at the Berlin Exhibition.

Key to Exercise VIII.

He has. He has not. Has he? Has he not? They had. They had not. Had they not? Have they not had? No, but they will have. When will they have? When they shall have been. Have they not been? They were, but we had already been. Will you not have had? Will you not have been? Shall we not have? You will have when you shall be; they will have, when they shall have been. Have they had? Will they not have? Had you? Had you? Were they? Are they? They are not, but they will be, when they will have had.

Note that the past participle, preceded by the verb *èssere*, always agrees both in gender and number with the subject of the sentence. Ex.: Egli è stat*o*, essa (she) è stat*a*, essi sono stat*i*, esse sono stat*e*; egli è andat*o* (gone), essa è andat*a*, essi sono andat*i*, esse sono andat*e*.

By Louis A. Barbé, B.A.

INDEFINITE PRONOUNS

The indefinite pronouns (*pronoms indéfinis*) are: *On, quiconque, quelqu'un, quelque chose, personne, rien, chacun, autrui, l'un l'autre, l'un et l'autre.*

1. *On*, one, they, people. *On* is very widely used in French. It is always the subject of a verb in the third person singular. It may be translated literally by "one," and occasionally by "some one":

(*a*) *On doit obéir aux lois,*
One must obey the laws.
(*b*) *On nous a indiqué le chemin,*
Someone showed us the road.

When (as in *a*) *on* has a collective meaning, and includes the speaker, it may be rendered by "we": "We must obey the laws." When it is collective, but does not include the speaker, *on* may be translated by "people," or by "they":

On craint ce roi et on lui obéit, mais on ne l'aime pas, People fear that king and obey him, but they do not love him.

Very often an English passive construction supplies the best rendering of a French sentence that has *on* for its subject: "That king is feared and obeyed, but he is not loved."

When *on* is preceded by *si*, if; *ou*, or; *où*, where; *que*, whom, that; *qui*, who, and *et* in which the final *t* is silent, it usually takes *l'* before it, to avoid the hiatus caused by two vowel sounds:

On n'aime pas à voir ceux à qui l'on doit tant,
We do not like to see those to whom we owe so much.

This *l'* must not be used when the word coming after *on* begins with *l'*:

On l'admire et on l'aime, He is admired and loved.

On must be repeated before every verb of which it is the subject:

On le loue, on le menace, on le caresse,
They praise, threaten, caress him.

2. *Quiconque*, whoever, is always followed by a singular verb:

Quiconque est riche, est tout,
Whoever is rich, is everything.

Words in agreement with either *on* or *quiconque* may be feminine if the sense absolutely requires it:

Quand on est mère on ne doit pas être coquette,
When one is a mother, one should not be a coquette;
Quiconque est vraiment mère n'est plus coquette,
Whoever is a real mother is no longer a coquette.

3. *Quelqu'un* has two different meanings, according as it is used absolutely—that is, without reference to a noun, or relatively, that is, with reference to a noun.

When *quelqu'un* is used absolutely it means "someone," "anyone," and applies to persons only:

Quelqu'un a dit que le soleil est l'âme du monde,
Someone has said that the sun is the soul of the world.

Quelqu'un doute-t-il sérieusement de l'existence de Dieu? Does anyone seriously doubt the existence of God?

When *quelqu'un* is used relatively, it applies to both persons and things, and means "some," "any," "a few." It is then used chiefly in the plural, and has either *de* and a noun after it, or *en* before the verb if the noun is understood:

Connaissez-vous quelques-unes de ces dames? Do you know any of those ladies?

J'en connais quelques-unes, I know a few of them.

Avez-vous encore de ces livres? Have you any more of those books?

J'en ai encore quelques-uns, I still have a few.

Quelqu'un, quelqu'une, quelques-uns, quelques-unes, require *de* before an adjective qualifying them:

Je connais quelqu'un de plus riche que lui,
I know someone richer than he.

4. *Quelque chose,* as an indefinite pronominal expression, requires words in agreement with it to be masculine, and adjectives qualifying it to be accompanied by *de*. It has the meaning of "something," "anything":

Il y a dans ce livre quelque chose d'incomplet.
There is something incomplete in that book.

Autre chose, something else, anything else, and ***grand'chose***, much, are used in the same way, and follow the same rule as *quelque chose :*

Avez-vous autre chose de curieux à nous montrer?
Have you anything else curious to show us ?
Il n'a pas fait grand'chose de bon,
He has not done much that was any good.

5. *Personne*, when joined to *ne*, is negative, and means no one. It is used without *ne*, and with the meaning of " anyone " in interrogative sentences, or in sentences expressing doubt. Words in agreement with it are masculine, and adjectives qualifying it are preceded by *de :*

Il n'y a personne d'assez hardi,
There is nobody bold enough.
Y a-t-il personne d'assez hardi ?
Is there any one bold enough ?

6. *Rien* is negative, and means " nothing," when it is accompanied by *ne*. It may be used without *ne*, and with the meaning of " anything " in interrogative sentences, or in sentences expressing doubt. Adjectives qualifying it take *de :*

Il n'y a rien de nouveau, There is nothing new.
Y a-t-il rien de plus désagréable ?
Is there anything more disagreeable ?

7. *Chacun*, like *quelqu'un*, may be used either absolutely or relatively. In the former case, it applies to persons only, and has no feminine form. It means " each one " :

Chacun croit avoir assez de sens commun, Each one thinks he has enough common-sense. When used relatively, it applies to both persons and things, and has a feminine form, *chacune :*

Ces gravures me coûtent cinquante francs chacune,
Those engravings cost me fifty francs each.
Chacun de ses enfants a remporté un prix,
Each of his children has carried off a prize.

8. *Autrui*, though rendered by the English, " others," is always singular. It may not be used as a subject, and only occurs in connection with *à* or *de :*

Attendez d'autrui ce que vous faites à autrui,
Expect from others what you do unto others.

9. *L'un l'autre*, one another, each other, has the feminine form *l'une l'autre*, and the plural forms *les uns les autres, les unes les autres.* In a sentence, the first part of this expression is always the subject, and the second part the object of the verb. Consequently, only the second part can have a preposition before it :

Ils médisent l'un de l'autre,
They speak evil of one another.
Les vrais chrétiens se pardonnent les uns aux autres,
True Christians forgive each other.

10. *L'un et l'autre* and its feminine form *l'une et l'autre* mean " both." When used with a personal pronoun, they cannot come immediately after it :

Ils rapportent l'un et l'autre les mêmes circonstances,
They both relate the same circumstances.

The plural forms *les uns et les autres, les unes et les autres* have no nearer English equivalent than " all " :

Ils se réunissent les uns et les autres contre l'ennemi commun, They all unite against the common enemy.

Exercise XVIII.

1. Where can (*peut*) one be better than in the bosom (*au sein*) of one's (*sa*) family (*famille*) ?
2. We have been told to (*de*) give you this.
3. They obey (to) that king because (*parce que*) they fear him, but nobody loves him.
4. He is said to be very rich.
5. Whoever has done that is a bad man.
6. If anyone speaks to you answer (*répondez*) him (to him).
7. I know no one here, and no one knows me.
8. If you have any more (*encore*) of those pears, give me a few.
9. Someone asks to (*à*) speak to you.
10. We have learnt (*appris*) something very interesting.
11. I know someone more powerful (*puissant*) than he.
12. We have not done much good to-day.
13. There is nothing more pleasant than travelling on foot (*de voyager à pied*).
14. Is there anything more surprising than this story ?
15. Each of my friends has carried off two or three prizes.
16. Do (*faites*) unto others what you would like (*voudriez*) that others should do (*fît*) to you.
17. I have spoken to both.
18. True Christians do not speak ill of one another.

Key to Exercise XVII.

1. Cette plume (-ci) est bonne, mais celle-là est meilleure.
2. Elle m'a montré son chapeau et celui de sa sœur.
3. J'aime mieux les nôtres que les leurs.
4. Si ce n'est pas lui c'est son frère.
5. Qui sont ces demoiselles ? Ce sont nos cousines.
6. Ce monsieur est-il avocat ? Non ; il est médecin.
7. C'est un de nos médecins les plus distingués.
8. Je ne connais pas ce monsieur ; je l'ai vu une ou deux fois, c'est vrai, mais je ne lui ai jamais parlé.
9. Il est vrai que nous ne lui avons jamais parlé, mais nous le connaissons très bien de vue.
10. Avez-vous fait cela ? Non ; ce n'est pas moi, c'est lui.
11. Si vous avez de plus belles gravures montrez-les-moi, je n'aime pas celles-ci.
12. Ce que vous venez de lire est très intéressant, mais ce n'est pas vrai.
13. Cette chambre-ci est plus petite que la nôtre, c'est la plus petite de toute la maison.
14. Donnez-moi un autre mouchoir, s'il vous plaît, j'ai perdu le mien.
15. Nos fleurs sont belles, celles de votre sœur sont encore plus belles, mais les vôtres sont les plus belles.
16. Cette bague n'est pas à moi, je n'en ai pas, elle est à une de mes amies.
17. Ce n'est pas sa bague, à elle, qu'elle a perdue, c'est la mienne.
18. À qui est-ce de jouer ? C'est à vous.

GERMAN

Continued from page [illegible]

By P. G. Konody and Dr. Osten

XXXIV. SUBSTANTIVES ONLY USED IN THE SINGULAR. Many *abstract* nouns which, being in themselves collective and synthetic terms, have no plural, as: die Furcht, fear, terror; der Neid, envy; der Glanz, splendour; der Geiz, avarice; die Jugend, youth; die Unſchuld, innocence, etc.; such *concrete* nouns, as: der Sand, the sand; der Schnee, the snow, etc.; and all nouns that are not substantives, but are used substantively, as: das Tanzen, the dancing; das Außeror'dentliche, the extraordinary. The concrete *effects* of abstract ideas and actions form a plural either in the ordinary way, or by circumlocution: die Dumm'heit (*s.*), stupidity; die Dummheiten (*pl.*), acts of stupidity, foolishness; das Glück (*s.*), luck, fortune; die Glücksfälle (*pl.*), strokes of luck; das Un'glück (*s.*), misfortune; die Un'glücksfälle (*pl.*), strokes of misfortune; der Betrug' (*s.*), fraud; die Betrügerei'en (*pl.*), fraudulent acts; der Dank (*s.*), thanks; die Dank'bezei'gungen (*pl.*), expressions of thanks.

1. The names of materials have as a rule no plural, but where different *kinds* of one material are concerned a plural can be formed, for instance: das Holz, (*s.*), wood, die Hölzer (*pl.*), different sorts of woods; das Geld (*s.*), money, die Gelder (*pl.*), the sums; das Gras (*s.*), grass, die Gräſer (*pl.*), the grasses; das Getrei'de (*s.*), cereals, die Getrei'dearten (*pl.*), the different kinds of cereals; das Korn (*s.*), corn, die Körner (*pl.*), the grains.

2. Some collective nouns are only used in the plural: die El'tern, the parents; die Geſchwi'ſter, German collective for brothers and sisters; die Gebrüder, brothers (when defining a business firm: Gebrüder Hope, Hope Brothers); die Leute, folk, people; die Oſtern, Easter; die Pfingſten, Whitsuntide; die Faſten, fasting, Lent; die Fe'rien, the vacation, holidays; die Blattern, smallpox; die Ma'ſern, measles; die Zinſen, interest (on capital), etc. Collective nouns denoting mountain ranges: die Alpen, the Alps; die Anden, the Andes; die Cordilleren, the Cordilleras; die Voge'ſen, the Vosges; but der Jura (*s.*), der Harz (*s.*), der Balkan (*s.*).

XXXV. The DEMONSTRATIVE PRONOUNS are: der (*m.*), die (*f.*), das (*n.*), that (not to be confounded with the definite article der, die, das); dieſer, this; jener, that; ſolcher, such, *or* such a; derjenige, he, *or* that; derſelbe, the same; (the two last being compounds of der and jenige, and der and ſelbe), each with three genders and one plural form.

The declension of the demonstrative pronoun der, die, das, differs only in the variation of the genitive and dative from that of the definite article.

	Singular		*Plural*	
nom.	der, die, das,	that	die	those
gen.	des (deſſen), der (deren), des (deſſen),	of that	der (deren, also derer),	of those
dat.	dem, der, dem,	to that	den (denen),	to those
acc.	den, die, das,	that	die	those

1. The alternative genitive and dative form (deſſen, deren, denen) is employed when the pronoun is used substantively: Die Blätter der Eiche unterſcheiden ſich von denen der Pappel, The leaves of the oak differ from those of the poplar. Obgleich England nicht ſo viele Soldaten hat als Deutſchland oder Frankreich, hat es deren genug, um ſeine Kolonien zu verteidigen, Although England has not as many soldiers as Germany or France, it has enough [of them] to defend its colonies.

(*a*) Deſſen and deren are also used as substitutes for the possessive pronouns ſein, his, and ihr, her, to avoid ambiguity. Example: der Vater erzählte von ſeinem Freunde und ſeiner Reiſe, The father spoke of his friend and of his journey. It is not clear whether the journey is that of the father or that of the friend; if the latter, deſſen must be substituted for ſeiner: der Vater erzählte von ſeinem Freunde und von deſſen Reiſe.

(*b*) The alternative plural genitive derer is only used when followed by the relative pronoun welcher and der (who, which): Das Him'melreich iſt derer, welche (die) Gott vertrauen, The Kingdom of Heaven is of those [belongs to those] who trust in God.

2. Dieſer, dieſe, dies (or dieſes), this; and jener, jene, jenes, that, follow the strong declension of the adjective [see XXVI.].

3. Solcher, ſolche, ſolches, such a, also follows the strong declension; but if used with the indefinite article it takes the inflections of the weak declension: ſolch-em Freunde (strong), to such a friend; but einem ſolch-en Freunde. Sometimes it is used in the shortened form ſolch for all three genders, followed by the indefinite article and without inflections: ſolch ein Mann, such a man; ſolch einer Frau, of such a woman; ſolch einem Freunde, to such a friend; ſolch einen Vater, such a father, etc.

4. In the compounds derjenige, diejenige, dasjenige, and derſelbe, dieſelbe, daſſelbe, der-, die-, das- take the strong, and -jenige, -ſelbe take the weak inflections.

	Singular	*Plural*
nom.	derjenige, derſelbe, etc.	diejenigen, dieſelben,
gen.	desjenigen, deſſelben, etc.	derjenigen, derſelben.
dat.	demjenigen, demſelben, etc.	denjenigen, denſelben.
acc.	denjenigen, denſelben, etc.	diejenigen, dieſelben.

Both these forms are always followed by the relative pronoun welcher, etc., or der, etc.: Derjenige, welcher (or der) Wind ſäet, wird Sturm ernten, He who sows wind will reap storm. Derjenige (or der) Mann iſt der ſtärkſte, welcher (or der) allein iſt, The strongest man is he who is [stands] alone. Es war derſelbe Mann, den ich ſah, It was the same man whom I saw.

5. The neuters of the demonstrative pronouns are not used with prepositions, but are replaced by compounds of these prepositions with the adverb of place da (dar before vowels): damit, with this (instead of mit dem, dieſem, demſelben); davon, of this, from this (instead of von dem, etc.); dadurch, through this; daraus, out of

this, etc. These contractions also replace the dative and accusative of dieſer and jener, and of the personal pronouns if they refer to inanimate objects. Examples: Hier iſt ein Gewehr, ſpiele nicht damit, Here is a rifle, do not play with it (damit replaces mit ihm, or mit demſelben); ich warte darauf (instead of auf es, or auf daſſelbe), I am waiting for it; wir ſprechen noch darü'ber (instead of über das, über dieſes, über es), We shall return to this subject [we will still speak about this].

6. The neuter demonstratives dies (lengthened: dieſes) and das are applied, with the auxiliary verb of tense ſein, to substantives, without the usual agreement in gender and number. Dies (dieſes or das) iſt mein Vater, dies meine Mutter, dies mein Kind, und dies ſind meine Schweſtern und Brüder, This is my father, this my mother, this my child, and these are my sisters and brothers.

XXXVI. Most *strong verbs* with the stem-vowel -e- change it in the imperfect into -a-, and in the past participle into -o- and -e- (which in the latter case means the return to the original stem-vowel). The verbs made prominent in print are conjugated with ſein, all others with haben.

Infinitive		Present Tense	Imperfect		Imperative	Past Participle
		I., II., III. Singular	*Indicative*	*Subjunctive*		
befeh'len	to command	ich befeh'le, befiehlſt', befiehlt'	ich befahl'	ich befäh'le *	befiehl	befoh'len
ber'gen	to save, shelter	ich berge, birgſt, birgt	ich barg	ich bärge	birg	geborgen
ber'ſten	to burst	ich berſte, birſteſt, birſt	ich barſt	ich bärſte *	birſt	geborſten
bre'chen	to break	ich breche, brichſt, bricht	ich brach	ich bräche	brich	gebrochen
dre'ſchen	to thrash	ich dreſche, driſcheſt, driſcht	ich draſch, also droſch	ich dräſche *	driſch	gedroſchen
empfeh'len	to recommend	ich empfehle, empfiehlſt, empfiehlt	ich empfahl	ich empfähle *	empfiehl	empfohlen
erſchre'cken †	to terrify, to be frightened	ich erſchrecke, erſchrickſt, erſchrickt	ich erſchrak	ich erſchräke	erſchrick	erſchrocken
gel'ten	to tell, to be valid	ich gelte, giltſt, gilt	ich galt	ich gälte *	gilt	gegolten
hel'fen	to help	ich helfe, hilfſt, hilft	ich half	ich hülfe	hilf	geholfen
nehmen	to take	ich nehme, nimmſt, nimmt	ich nahm	ich nähme	nimm	genommen
ſchelten	to scold	ich ſchelte, ſchiltſt, ſchilt	ich ſchalt	ich ſchälte *	ſchilt	geſcholten
ſprechen	to speak	ich ſpreche, ſprichſt, ſpricht	ich ſprach	ich ſpräche	ſprich	geſprochen
ſte'chen	to sting	ich ſteche, ſtichſt, ſticht	ich ſtach	ich ſtäche	ſtich	geſtochen
ſtehlen	to steal	ich ſtehle, ſtiehlſt, ſtiehlt	ich ſtahl	ich ſtähle *	ſtiehl	geſtohlen
ſterben	to die	ich ſterbe, ſtirbſt, ſtirbt	ich ſtarb	ich ſtürbe	ſtirb	geſtorben
treffen	to hit, to meet with	ich treffe, triffſt, trifft	ich traf	ich träfe	triff	getroffen
verber'gen	to hide	ich verberge, verbirgſt, verbirgt	ich verbarg	ich verbärge	verbirg	verborgen
verder'ben	to spoil	ich verderbe, verdirbſt, verdirbt	ich verdarb	ich verdürbe	verdirb	verdorben
werben	to enlist, woo	ich werbe, wirbſt, wirbt	ich warb	ich würbe	wirb	geworben
werfen	to throw	ich werfe, wirfſt, wirft	ich warf	ich würfe	wirf	geworfen
‡						
eſſen	to eat	ich eſſe, iſſeſt, iſſt	ich aß	ich äße	iß	gegeſſen
freſſen	to eat (devour)	ich freſſe, friſſeſt, friſſt	ich fraß	ich fräße	friß	gefreſſen
geben	to give	ich gebe, gibſt, gibt	ich gab	ich gäbe	gib	gegeben
gene'ſen	to recover	ich geneſe, geneſeſt, geneſt	ich genas	ich genäſe	genes(e)	geneſen
geſche'hen	to happen, to take place	es geſchieht	es geſchah	es geſchähe	geſcheh(e)	geſchehen
leſen	to read	ich leſe, lieſeſt, lieſt	ich las	ich läſe	lies	geleſen
meſſen	to measure	ich meſſe, miſſeſt, miſſt	ich maß	ich mäße	miß	gemeſſen
ſehen	to see	ich ſehe, ſiehſt, ſieht	ich ſah	ich ſähe	ſieh	geſehen
treten §	to step	ich trete, trittſt, tritt	ich trat	ich träte	tritt	getreten
vergeſ'ſen	to forget	ich vergeſſe, vergiſſeſt, vergiſſt	ich vergaß	ich vergäße	vergiß	vergeſſen
gebären	to bear, to bring forth	ich gebäre, gebierſt, gebiert	ich gebar	ich gebäre	gebäre, or gebier	geboren

* Also with ö. † As intransitive (without complement) *strong:* ich erſchrak, I was frightened; as transitive (with object) *weak:* ich erſchreckte ihn, I frightened him.

‡ To this group belongs also gebären, to bear, which is to be found at the end of the list of this group. § Also with haben in the sense of "to tread on."

EXAMINATION PAPER X.

1. Which substantives are used only in the singular, and which only in the plural?
2. How can a plural be formed of some nouns which in themselves have no plural?
3. To which declension do the demonstrative pronouns dieſer and jener belong?
4. In which cases does the declension of the demonstrative pronoun der, die, das differ from that of the definite article?

5. Which declension is taken by the demonstrative pronoun ſolcher, ſolche, ſolches?
6. Which declension is used with the shortened form of the demonstrative pronoun mentioned in 5?
7. In which cases is the use of the alternative genitive of the demonstrative pronoun der, die, das (that) indispensable?
8. Which relative pronouns *must* follow the demonstrative plural genitive derer (of those)?
9. Which declension is followed by each of the two components of the demonstrative pronouns derjenige and derſelbe, and by which relative pronouns *must* they be followed?
10. Can the neuters of demonstrative pronouns be used with prepositions?
11. Which compounds replace the neuter of the personal pronoun in connection with a preposition governing the dative or accusative?
12. When is the neuter demonstrative dies exempt from the customary rules of agreement in gender and number?
13. Which are the vowels taken in the imperfect, in the past participle, and in the second person singular imperative, by strong verbs with the stem-vowel -e-?
14. Why is it, in some cases, preferable to use the first conditional instead of the imperfect subjunctive, with verbs whose stem-vowel is -e-?

Exercise 1. Change the present tense of the following sentences into the imperfect and into the perfect [see XXXIII.]:

Ich binde einen Kranz; der Vogel ſingt; das Reh
I bind a wreath; the bird sings; the deer
ſpringt und trinkt; das Werk gelingt; wir trinken
jumps and drinks; the work succeeds; we drink
Wein; das Waſſer rinnt ins Thal; er ſchwimmt
wine; the water flows into the valley; he swims
ausgezeichnet; ich ſitze im Garten; das Schiff ſinkt;
excellently; I sit in the garden; the ship sinks;
die Glocke klingt laut; der arme Mann bittet um
the bell sounds loudly; the poor man begs for
eine Unterſtützung; ich gewinne das Spiel;
assistance (aid); I win the game;
er beſitzt ein Haus.
he owns a house.

Exercise 2. Insert the missing demonstrative pronouns and other parts of the sentences:

Ein . . . . ſelten; . . . . ein . . . . ;
Such a friend is rare; such a friend is rare;
. . . . ;
he is the son of this man and of that woman;
wir ſprachen mit (3) . . . . Knaben . . . . ;
we spoke to this boy and to those men;
. . . . viel . . . .
she spoke much of her daughter and of her
. . . . ; der Himmel iſt
[the daughter's] experiences*; Heaven is
. . . . gnädig, die ihn anrufen; der Jäger
gracious to those who appeal to it; the gamekeeper
marſchierte hinter ſeinem Herrn und trug
marched behind his master and carried
. . . . Gewehr; ich vertraue . . . . . ., welcher
his [the master's] gun; I trust to him, who
mir vertraut; . . . . ? . . . .
trusts me; is this your wife? No, this is my
. . . . . . ; . . . . ;
cousin*; these are her sisters and their husbands*;
ſie antwortete, ſie würde . . . . Mann heiraten,
she answered she would marry that man
. . . . . . ihr am beſten gefiele.
who pleased her best.

Exercise 3 (*a*). Rearrange the following sentences by putting the indefinite article *before* the demonstrative pronoun:

Es iſt eine Freude, ſolch einen Sohn zu haben.
It is a joy to have such a son.
Solch' ein Un'glück! Solch' eines Mannes Sohn
Such a misfortune! The son of such a man
ſollte von anderer Art ſein. Wie konnten
ought to be of different stuff [kind]. How could
Sie ſolch einer Frau ſolch eine Unhöflichkeit ſagen?
you say so rude a thing to such a woman?
Solch ein Tag iſt ſchrecklich. Solch einem Künſtler
Such a day is terrible. To such an artist
muß man ſolch einen Irrtum verzeihen.
one must forgive such a mistake.
Solch einem Manne, ſolch einer Frau, ſolch einem Kinde
Such a man, such a woman, such a child
bin ich noch niemals vorher begegnet.
I have never met before.

(*b*). Rearrange the following sentences by putting the demonstrative pronoun *before* the indefinite article:

Ein ſolcher Skandal' wegen einer ſolchen Klei'nigkeit!
Such a scandal on account of such a trifle!
Eines ſolchen Mannes Pflicht iſt Großmut; einem ſolchen
Such a man's duty is generosity; in face of such
Un'glück gegenü'ber iſt der Menſch wehrlos; einen ſolchen
a misfortune man is helpless; such a
Fall habe ich in einer ſolchen Familie noch nicht erlebt!
case I have never experienced with such a family!

KEYS TO EXERCISES IN EXAMINATION PAPER IX.
(PAGES 2051-2)

Exercise 1. Ich beeile mich; er beeilt ſich; du liebſt dich; wir retten uns; ich ſagte mir; Sie ſagten ſich; ihr ſagtet euch; ſie fürchteten ſich; ich hatte mir geſagt; wir hatten uns ruinirt; er würde ſich getötet haben; ſie unterhält ſich; wir unterhielten uns; ſchämen Sie ſich! raſiere dich!

Exercise 2. Ich habe einundzwanzig Karten; er gab mir zweihunderteinundſechzig Pfund für das Jahr tauſend neunhundert und eins; der Lehrer unterrichtet zweiundvierzig Knaben und ſiebenundfünfzig Mädchen, zuſammen neunundneunzig Kinder. Im ruſſiſch-japaniſchen Kriege wurden zweihundertſiebenundvierzigtauſend fünfhundert und achtundneunzig Soldaten verwundet — hundertfünfundvierzigtauſend vierhundert und ſiebenunddreißig Ruſſen und hundertzweitauſend einhundert und zweiundfünfzig Japaner. Wie viel iſt neunzehn und dreizehn? zweiunddreißig; vierzehn und neun? dreiundzwanzig. Einer von euch hat es genommen. Ich glaube es war der eine von den fünf Soldaten; er war der Vater zweier Söhne; er war der Vater von zwei Söhnen.

---

* The experience, die Erfahrung; the cousin, die Couſine; the husband, der Gatte.

THE FIRST ENGLISH KINGS

Mahomet's Successors. Hengist and Horsa. Alfred and his Reign. Work of St. Dunstan. King Canute. William the Conqueror

Continued from page 2244

By JUSTIN McCARTHY

MAHOMET did not designate his successor to the caliphate or sovereignty which the dying man had created for himself. The title of caliph, which meant lieutenant or vicar of the almighty ruler, came originally from Persia, and was adopted by the Arabians over whom Mahomet came to rule. Mahomet was attended in his latest illness by one of his closest and most powerful friends, Abou-Bekr, whose daughter Ayeshah he had married, and whom he had charged with the duty of pronouncing a farewell message to those around him and to all his subjects. Abou-Bekr was chosen as the successor to Mahomet, and the office of caliph meant the absolute direction of religious, civil, and military affairs. The successor to Abou-Bekr was Omar, and Omar was followed by Othman, and then came Ali, stepson of Mahomet. Ali was said to have been the very first convert made by Mahomet to the Mussulman doctrine, and he was one of the bravest and most devoted followers of the Prophet, whether in peace or in war. His accession to the caliphate gave rise to a religious and political dispute among the Mussulmans, which made its mark upon their history. A large proportion of that party had strongly maintained that Ali himself ought to have been the immediate successor to Mahomet, and during the years which intervened between Mahomet's death and Ali's accession to the caliphate something like a sectarian division sprang up among the Arabian people.

The Arabian Caliphs. After the death of Ali, the caliphate became hereditary, and the Arabs soon began to undertake great expeditions and conquests, with the purpose mainly of compelling the neighbouring nations to accept the doctrines of Mahomet and the Koran. Within a few years Arabian caliphs had made themselves masters of Persia and Egypt, the invasion of Egypt being signalised by a siege of Alexandria which lasted for more than a year. From this time the caliphs became a trouble to all that part of the world within their reach, and in later days they became a trouble even to Europe itself. The Arabian caliphs, indeed, only followed the example which had been set them by the Roman Empire, and the world has seen that civilised and modern States have undertaken the conquest of foreign countries with the avowed object of spreading among them the teachings of true religion. The caliphate dynasties were, in the meanwhile, subject to frequent disturbances, interruptions, and divisions. One sect—that of the Abbassides—set up on its own account, and founded a dynasty of its own. This dynasty claimed to have had its origin from an uncle of Mahomet, and founded a dominion which was described as the Eastern dynasty, and made its capital at Bagdad, a new city built for that purpose on the Tigris. This caliphate gave to the world a succession of famous rulers, most of whom did their best to introduce into the life of the East all the literature, art, and science which had been, and still were, given forth from Greece and Italy.

The Arabian Nights. The most famous of this line of caliphs is Haroun-al-Raschid, or Haroun the Just, whose name has been made known by "The Arabian Nights" to all readers of books, whether adults or children, throughout the world. The adventures which befell Haroun and his favourite Minister Giafar in their nocturnal wanderings through the various quarters of Bagdad have exercised a fascination over most minds at one time or another such as fairyland itself could not surpass. It is to be feared that the impression of Haroun himself which is got from "The Arabian Nights" is scarcely more true to the original than is the picture given of the nocturnal adventures of the caliph and his comrade to the actual conditions of life in Bagdad. Haroun-al-Raschid was, indeed, a great lover and patron of art and letters, and a generous friend to all who deserved distinction in those spheres; he made his Court at Bagdad the centre of all that was brilliant, artistic, and intellectual among his own people or among travellers whose wanderings led them to that part of the world. But it is certain that Haroun the Just does not stand out through the whole of his career as a typical crowned representative of justice. He was luxurious and extravagant in his habits, even for an Oriental sovereign, and indulged in acts of despotic severity not common even among despots. He became possessed by hatred towards the race of the Barmecides, a tribe or race of Persian origin, whom he suspected of designs against himself or his dynasty, and caused the execution of many of the leading Barmecides and their sons. His own grand vizier Giafar, the favourite companion of his life and wanderings, was himself a Barmecide, and in his sudden outburst of fury Haroun ordered the execution not only of Giafar, but of his sons as well.

The Barmecides. The race of the Barmecides has, through the pages of "The Arabian Nights," been enabled to bequeath to English literature a phrase which is in use even at the present time. We still speak of a Barmecide feast when we mean to describe a banquet at which there was little or nothing to eat or drink, and the phrase is taken from the story told by the barber's sixth brother in this immortal story-book.

Haroun-al-Raschid, while marching against a rebellion in one of his provinces, was assailed by a fit of apoplexy, which brought his career to a sudden end. The dynasty of the Barmecides did not maintain its power long after his death, but the Mahommedans continued to be an important factor in the world's history for many succeeding centuries. They made themselves again and again a terror to Europe, and were able to establish settlements for a length of time on European soil.

Influence of Mahommedanism. The Mahommedans, in fact, accomplished the greatest movement of change known to the earth since the Roman Empire ceased to be a ruling power. They obtained, indirectly at least, a very marked influence over the world's literature, as well as over its history, for there was a certain fascination about their life, their manners, their stories, and their poetry, which impelled European writers to make them a constant study and to enrich European romance with ideas, descriptions, and pictures from the storehouse of the Orient. Mahomet the Prophet could never in his wildest imaginings have foreseen the peculiar influence which his people were destined to have on the literature of the world. That influence survives even in the literature of our own days.

The most important work of the Middle Ages consisted in the division of Europe into separate states, representing the several nationalities and characteristics of the European populations. During some centuries this development had been sought after under most difficult conditions, and was interrupted by opposing incidents and forces of various kinds. At one period the classification of the separate nationalities was confused and unsatisfactory. The Franks, and the Gauls, and the Northmen were understood to be made up of the German, the French, the Swedes, Danes and Norwegians. But in process of time it became impossible to consider the Franks as entirely Germanic, or the Gallic nationality as including only the inhabitants of France, or even the inhabitants of that part of Europe which was then regarded as purely Gallic.

The Danes. The Danes were the most venturesome and most powerful of the Northern peoples, and had made their way, by repeated invasion, into countries which they were able to occupy for a time, but which before long compelled them to see that they were looked upon as foreign intruders whose sway could not be endured. In the South of Europe the Spanish races had not yet been clearly marked out into the separate kingdoms which afterwards came to be recognised; and Spain itself had been occupied successively by Carthaginian, Roman, and Moorish invaders. Italy, after the fall of the Roman Empire, had become in great part the centre of Christianity and the home of the Papal power. For a long period one of the world's great struggles was that of Christianity against one or other form of Pagan belief. Rome, representing no longer the Empire of the Cæsars, had come to represent the influence and the power of the Popes and the Popes' claim to occupy the Chair of St. Peter. Russia was regarded as a barbaric region out of touch with the growth of European civilisation.

The Development of States. Gradually, as we have seen, the different nationalities began to shape themselves into separate states. The kingdoms of England and France secured for themselves distinct recognition. The Germanic race, although divided even to our own days under separate governments and systems, had come to be recognised as entirely distinct from the other peoples of Europe. Italy was divided into small states, but was recognised as representing a common nationality. Hungary, after being subjected to the Romans, and afterwards taken possession of by the Goths, was occupied by a Scythian tribe, the Ungrui—from the German version of which name, Ungarn, we get the present name of the country—and by the Magyars, a race of Finnish origin.

It must not be supposed that the principle of nationality was, or ever could be, distinctly preserved in these various settlements. The configuration of the soil, the limits made by Nature as convenient frontier lines, by the sea or by the position of great mountain ranges, or long and broad rivers, had necessarily much to do with the formation of the different states.

The British Islands. We may take the illustration given by the British Islands. These islands would seem clearly marked out by the sea as the natural home of one separate people. But the northern part of the larger island, the Scotland of history, was peopled by a race of men who had not a common origin with the people of England, who spoke for a long time a different language, and had for centuries kings of their own. The other island, Ireland, claimed an origin quite different from that of either Scotland or England, spoke in a tongue almost the same as that of Scotland, and for many centuries was held by England merely as a captive province. Even England herself enclosed people who did not admit a common nationality with that of the English race—the Welsh, who claimed an entirely different descent and spoke a language akin to that of Scotland and of Ireland. The Norsemen, the Danes, Swedes, and Norwegians, while generally regarded by the outer world as representing alike the nationality, the traditions, and the purposes of the people commonly called the Norsemen, never blended, during the course of their history, into one common race and state. The Northmen invaded and made settlements in France, England, and the Netherlands; they invaded Russia, and pressed on to the Polar regions. The Saracens—a name given to the Arab-Berber races of Northern Africa as well as to other Arab races of Asia and of Africa—were famous sea-rovers, who invaded both the western coasts of the Mediterranean. The Hungarians also made a deep mark on the history of the Middle Ages, for they, too, were filled with the spirit of adventure and conquest.

All these various invasions were in time repelled from the foreign countries which they had threatened and endeavoured to occupy, and

Europe began to shape herself into the states which are, for the most part, still existent. The one state which may be regarded as destined to some comprehensive change is that of European Turkey.

Beginnings of the English Race. We may begin the story of the European kingdoms with the history of England. Mr. J. R. Green, in the beginning of his "Short History of the English People," tells us that "for the fatherland of the English race we must look far away from England itself." Then he reminds us that "in the fifth century after the birth of Christ the one country which bore the name of England was what we now call Sleswick, a district in the heart of the peninsula which parts the Baltic from the Northern Seas." The inhabitants of that region were of Teutonic origin. They were known as Saxons by the Romans; and like other nations of that day were much given to the use of ships and to exploring expeditions, with the object of finding out promising and profitable places of settlement. England had been for a long time a province of Rome, and some of her population were already taking to Roman ways and the Roman language; while in other parts of the island the resistance to Roman power was unceasing, and called for successive conquest on the part of Rome. But when the Roman Empire began to fall into decay, and Rome had quite enough to do in the defence of her own Italian regions, there came at once the temptation and the opportunity for the Sleswick races to attempt an expedition with the object of establishing a settlement in the island of Britain. An expedition started in the year 449 A.D., under the leadership of Hengist and Horsa, and landed, as Roman expeditions had done before, on the shores of the Isle of Thanet.

English History Opens. With this landing the history of England begins. The expedition is said to have been invited by Vortigern, one of the many rulers among whom the island of Britain was divided, his object being to obtain the assistance of these renowned adventurers in a struggle against the Picts, the Northern race of the island, with whom war was continually going on. It is believed that Vortigern married Rowena, the daughter of Hengist, in order the better to secure the support of that leader. As we have already seen, the brothers subsequently turned against Vortigern, and made war on him, but were defeated in a battle in which Horsa was killed. Hengist persevered in his adventurous undertaking, and, according to tradition, made himself master of all the Kentish region. He died in Britain many years after. Some considerable time had yet to pass before Britain became united as one kingdom; it had many foreign rulers, and even foreign dynasties.

We need not retrace the history, such as it is, of all these various reigns. Much of the narrative rests on tradition, or on records of very imperfect order. We do not need to make any more than a passing mention of the half-mythical or wholly mythical King Arthur, who is said by some chroniclers to have lived and reigned at an undefined period of the sixth century. King Arthur and his Knights of the Round Table make their appearance again and again in legends or in pretended chronicles of England, Scotland, Wales, and even of France; and if we were to attach any real importance to these chronicles and legends we should have to assume that King Arthur appeared again and again in life during far divided periods of the world's history, even as one of the divinities of the Greek or Roman mythology might be supposed to do. One success may be ascribed to him whether he be mythological or no—he has created a remarkable figure in the literature of poetry and prose.

Alfred. There are, however, some distinguished names to be recorded during this long period—some English rulers who made an enduring mark, not only on the history of England, but on the history of the world.

Alfred the Great, as he was justly called, won for himself what promises to be an undying celebrity. He was King of the West Saxons; was born in Berkshire, in 849, and was taken to Rome to pass there some of his early years. He was the youngest of five sons born to his father, King Ethelwolf; but in 871, at the age of twenty-two, he succeeded to the throne on the death of his brother Ethelred. At that time the Danish occupation of England was growing more and more widespread, and, indeed, the greater part of England north of the Thames was under Danish rule. Alfred, before his accession, had served in a battle against the Danes, and the victory of Ashdown was won chiefly by his courage and military genius.

After Alfred's accession there were nine battles between the Danes and West Saxons, and some years later Guthrum, who ruled over the Danes of East Anglia, made a sudden invasion of Wessex, at first with complete success. Alfred's military resources were for the time exhausted, and he had to abandon resistance and find a temporary place of refuge for himself and the remainder of his forces in the marshy regions of Somersetshire. Here, raising a fort at Athelney, he maintained himself and his followers. It is certain that during that period he spent his time chiefly in making preparations for another attempt against the Danes. In the same year, 878, not long after his retreat, he suddenly came forth at the head of an army and inflicted a complete defeat on the Danes. The Danish sovereign, Guthrum, had to accept terms of peace, one of these being to receive baptism as a Christian; he had also to acknowledge the supremacy of Alfred in all the regions south of the Thames and in the greater part of Mercia.

Alfred as "Over-ruler." The Danes still retained their hold of East Anglia, but Alfred regarded them as merely foreign invaders, and continued his preparations for their complete expulsion. He sent out a fleet against them in 884, and two years later occupied London and fortified it. In 893 Northumbria accepted him as its sovereign, and he finally became the acknowledged "over-ruler" of Britain.

Alfred had, however, from time to time, more trouble with the Danes on account of his anxiety to relieve the country as far as possible from their disturbing presence. Despite his many wars, he had long intervals of peace, which he employed to the noblest account.

Administration of Alfred. Though he had come to be recognised as the ruler of all Britain, this position was not that of a sovereign as reigning over one undivided State. There still remained during Alfred's time several minor kingdoms with their hereditary kings; but Alfred was recognised as holding a position higher than all these, and representing the whole people of Britain. Throughout his long and methodical labour for the improvement of the realm he had as closely in his mind the interests of one part of the country as of another. He busied himself with works of improvement, which extended their influence from the southern shores to the extreme north of England. He took measures for the defence of his country along its coast, and for the bettering of the system of legislation which he found existing in the realm. His exertions mitigated the savagery of some of the penal laws which still prevailed, and he did his best to construct a codified and equalised system of legislation for the whole country. He had no dreams of foreign conquest: his ambition lay nearer home.

While organising these reforms, Alfred devoted himself to his daily tasks with an application which would have done credit to the most hard-working member of a business firm. While engaged in the establishing of schools throughout the country, he actually superintended the educational work of a school he had founded for the sons of the nobility around his Court. With all his practical work, he was an intense lover of music, and by his influence and example did much to promote the spread of a cultured taste for music among all who looked up to him as a spreader of light. He was a scholar and a literary man as well as a maker of laws; he translated the celebrated book of Boethius, the Roman author, on "Philosophy's Consolation," histories written by the Venerable Bede and by Orosius, and other great foreign books. No man ever devoted himself more thoroughly and more unceasingly to the promotion of education, morals, prosperity and happiness among his fellow men than Alfred did throughout the whole of his reign.

The Alfred of Story-books. There are numbers of legends retained in literature concerning Alfred and his days. One of the most familiar of these is the famous story of Alfred's entering a peasant's cottage, not being recognised by the wife of the house-owner, and offering to assist her in the baking of her cakes. Alfred cheerfully consented to do the work, and the woman left him in order to attend to some of her outdoor duties. In her absence the King, becoming absorbed in thoughts concerning the welfare of his realm, forgot all about his appointed task, and allowed the cakes to burn. The good woman returned to find her cakes spoilt, and the young man who had undertaken to look after them not paying the slightest attention to them. She relieved her feelings by violently scolding her unrecognised sovereign, who listened with bland good humour and without a word of remonstrance. The legend is even still a subject of allusions in English writings. It is in all probability a myth, but a myth which effectively illustrates the manner in which Alfred was regarded by his own people. No such story would ever have been told of a monarch who was not recognised as conspicuous for his sweetness of temper and keen appreciation of humour.

Alfred died on the 27th of October 901, at the age of 52.

Then came the reigns of successive rulers, one of whom was regarded as supreme over all the rest, according to the precedent which had been set up in the days of Alfred. The Danes continued their invasions and settlements, and the whole story of those years is but a repetition of the efforts to obtain England for the secure ownership of the English. There were struggles, too, with the Welsh, for some of the English kings endeavoured to invade Wales, and Wales in return sometimes invaded England.

St. Dunstan. One of the most important and picturesque figures of those times was that of Dunstan, the famous ecclesiastic known to the world as St. Dunstan, Archbishop of Canterbury. He was the son of a West Saxon nobleman, was born in 924 A.D., and was educated at Glastonbury Abbey, where he took the monastic vows, and for a time lived the monastic life. He was, however, by nature designed for the work of education and of reform, not merely in ecclesiastical but also in political affairs. On the accession of Athelstan's brother Edmund, he went to Court, and after a period of disfavour was appointed Abbot of Glastonbury in 945. Then he began with effect his great work as an educational reformer, and was at the same time the close adviser of King Edmund. Dunstan had among many artistic qualities a passionate love of music, and in his wanderings through the country he carried his harp in his hand, and struck its chords to delightful music, after the fashion of the harpers renowned in early song and story. He did not obtain the support of Edwy, the successor of Edmund, and there was a strong feeling against him amongst some of the courtiers whose advice was powerful with the new King. Dunstan left the country and took refuge in Flanders, but was afterwards recalled to England; during the reign of Edgar he was created Bishop of London.

After Edgar became supreme King of Britain, he appointed Dunstan Archbishop of Canterbury. Dunstan took part with the Archbishop of York in the Coronation of King Edgar on Whit Sunday 973, a ceremonial intended to demonstrate that the whole kingdom of Britain was thenceforward to be recognised as one realm. The great object of Dunstan's statesmanship was to establish and maintain a national policy while establishing also the principles of equality, fairness, and justice in the civil code of the realm. Even the Danes in England he would not regard as enemies, but endeavoured to make them good citizens of the country by allowing them to retain their own nationality and customs.

Britain as One Realm. For sixteen years Dunstan ruled under King Edgar not only the ecclesiastical but also the civil affairs of the State. During all this time there was peace in England, whose condition seemed to be in every way improving. On the death of Edgar, in 975, Dunstan gave his support to Edward, elder son of the late King, and performed the coronation ceremony at Winchester. In 978 Edward was murdered at a feast by a robber whom he had banished from his realm; and it was mainly owing to Dunstan's firmness and energy that the succeeding prince, thus called so suddenly to the throne, was able to maintain the order of the realm without interruption. During Dunstan's administration continuous efforts were made to abolish the system of slavery which had prevailed up to that time in almost every country, and his efforts were so far successful that they impressed the intelligent public with a sense of the horror attaching to the system. From that time forth there was a continuation of the policy, which may be said to have had its first political impulse from Dunstan, which attempted not merely the abolition of slavery horrors but the creation of a public opinion which should lead to its entire abolition.

Canute. Dunstan died at Canterbury in the year 988, and his death seemed to have given a new opportunity for that spirit of disunion and disorder which he had so long been able to repress. The several kingdoms reasserted their independence, and in each of them lawlessness began to prevail. The West Saxons rose in one region, the Danes occupied another. The latter captured Canterbury, and there Ælfheah, the Archbishop, was murdered.

For a time England seemed to be given up to strife between the North and South for supremacy, with frequent interruption of invasions by the Danes and the efforts towards their expulsion. Edmond Ironsides, one of the English overruling sovereigns, struggled for a while, and with some apparent success, against the conquering Danes, under the leadership of Canute; but he was overthrown in a decisive battle, and his death shortly afterwards left Canute master of the field. Canute was not a foreigner in anything like the same sense as the Norman rulers who governed England in later days. The language of his forefathers differed far less from that of the earlier English stock than did the language commonly spoken in many of the districts which had lately set up as separate states in England.

Canute was one of those men who only show their true nature when they become exalted to a position which enables them to follow the dictates of that nature without compromise and without consideration for opposing influences, whether of race or of tradition. He had sanctioned, ordered, and even committed many acts of capricious cruelty before he became recognised as the highest ruler in Britain; but on his arriving at that supreme eminence he became at once the genuine Canute. He had a great intellect, a keen power of observation, and a sincere desire to make his people happy and himself beloved by them. He devoted himself to a policy of humanity and justice, an effort to introduce the principle of civil equality into the government of the island, to maintain peace within his own dominions, and to enable every one of his subjects to enjoy in security the results of his own industry, skill, and good behaviour. Canute had in him much of the artist as well as of the statesman, and composed poems which are still recorded in the history of literature. His great aim was to carry out in the rule of England the principles of Dunstan; and he did all that he could by precept and example to uphold the belief that communities must be governed by religion and its teachings in the first instance, and by systems of civil law consistent with such doctrines. He had a great scheme, which he regarded as patriotic and practicable, but which proved in the end a fatal obstacle to the complete realisation of his best ambition.

Canute's Dream of Federation. He desired to unite some of the Northern Powers of Europe, such as Denmark and Norway, into a complete confederation with Britain, under his own rule, and to govern these countries by equal and enlightened laws. This project did not at the time seem so chimerical as it might have done some ages later. There was then no English people as we now understand the words. A great part of the island had been occupied and settled by peoples and rulers of different races, and Canute regarded the northern men as having the best and nearest claim to relationship with the England of the past. The project was, however, beyond his power of accomplishment; and if Canute could not have carried it to success, we may feel sure that no other man in his place could have done more than he.

England was beginning to concentrate herself within her own sea-washed shores, and to endeavour to found a distinct nationality there. Some of Canute's domestic measures, such as the forest laws, which he introduced with the object of reclaiming vast tracts of land that had been allowed to run to waste or had become the home of wild animals, were regarded with disfavour by many of his subjects, who did not approve of any disturbance offered to the old and traditional ways of the country. His reign was, on the whole, one of peace and general content, and forms a most important landmark in the history of England. He died on the 12th of November, 1035, and was laid to rest at Winchester.

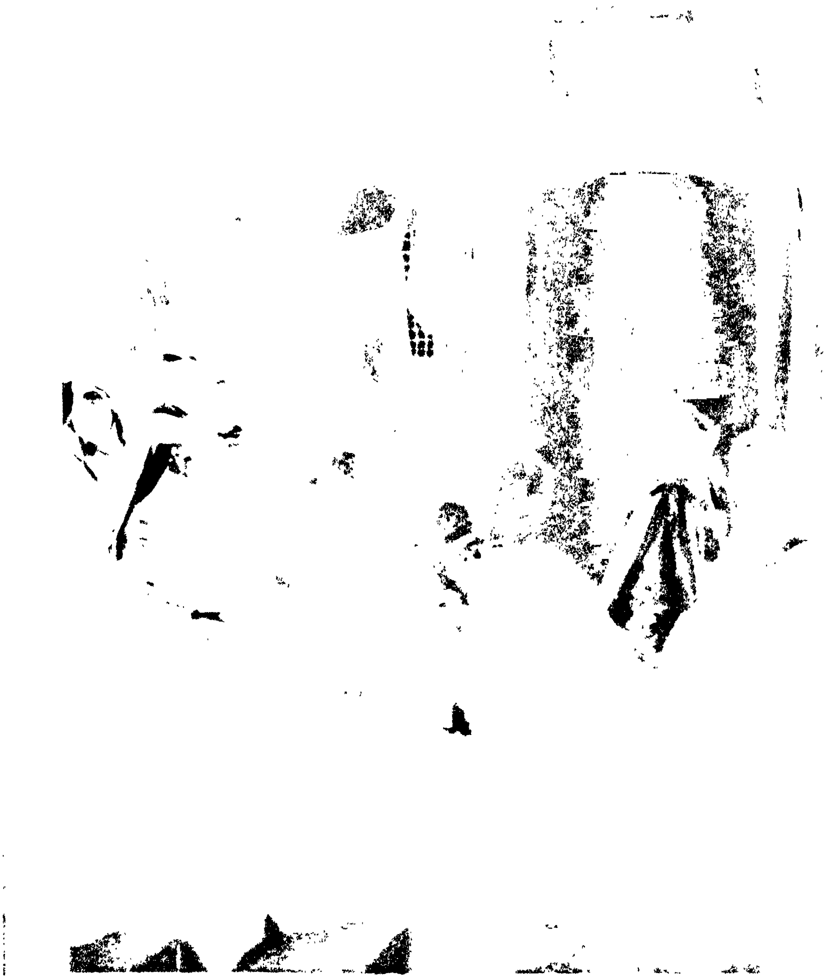
Character of Canute. Many instances are recorded of Canute's nobility of character, his generosity, and his appreciation of the duties which belong to a throne. One of the most famous stories tells of the stroke of practical humour with which he turned to ridicule the grotesque flattery of some of his courtiers who thought to please him by declaring that he was privileged to execute omnipotent rule over all the conditions of life within his realm. While sitting on the seashore as the tide was coming in the King offered to test his power over the elements by commanding the waves to recede or stand still. The waves, however, held on their way, and the monarch and his too flattering courtiers had to take flight to escape being swallowed up by the sea.

A Period of Unrest. After the death of Canute came an interval of renewed wars and troubles, and a succession of Danish and Saxon kings whose reigns did little for the progress of England's civilisation. Canute's dreams of a great and abiding union between England and the northern countries came to nothing. The Danish kings who succeeded Canute were for the most part barbaric tyrants; and the fact that Canute had been able to establish for so many years a rule of peace, order and justice, made the inhabitants of Britain more impatient of the wanton misdeeds committed by those who came after him. The rule of the Danish sovereigns soon came to an end. A remarkable figure among these later kings was that of Godwine, Earl of the West Saxons. Mr. Green tells us that "Godwine is memorable in our history as the first English statesman who was neither king nor priest." He was a man of humble birth, and according to some authorities, the son of a peasant, but he succeeded at an early age in making himself remarkable by his practical ability and versatility. He thus became useful to Canute's brother-in-law, and his success carried him so far that he became Earl of Wessex. He has an especial interest because of the important position he took in bringing about the change in English feeling which led to the extinction of Danish rule in Britain and the establishment of the line of Norman sovereigns after Edward the Confessor. Godwine had done his best after the death of Canute to maintain the policy of the late Sovereign, and to prevent the breaking up of the Danish rule; but the acts of Canute's Danish successors made it clear that this policy had no hope of success. Godwine died in 1052. His daughter was married to Edward the Confessor, the last of the old line of Anglo-Saxon kings. The history of Edward's reign illustrates the continuance of the struggles between the several factions and influences which were groping about for some policy destined to secure a continued nationality and system of government for Britain.

William, the Man of Destiny. The man was coming to the front whom destiny would seem to have created for the purpose of giving to Britain a line of continuous sovereignty with which no minor or local rulers were to interfere. He was born in Normandy and will ever be known as William the Conqueror. He was the illegitimate son of Robert, Duke of Normandy, and his mother is said to have been the daughter of a poor tanner whom the Duke of Normandy had seen washing linen in a stream near his palace, and with whom he fell in love. William was protected and brought up by his father, and when the father died, leaving no legitimat heir, the influential nobles of the Court accepte him as successor to the dukedom. Th dukedom was then a dominion, resembling i its nature some of the minor sovereignties c Britain, and the young duke had much troubl to contend with. Some of the nobles of th duchy rose in rebellion against him, an King Henry of France had to come to his help with a strong force to enable him to crush th rebels on the battlefield. William visite England in 1057, in order that he might spend some time with his cousin Edward the Confessor; and during their intercourse he was encouraged by Edward to think of obtainin the succession to the English throne.

Qualities of William. William impresse all around him with the sense of a commandin individuality. He seemed to concentrate int a single form that era of warlike enterprise, of invasion and of conquest, which was drawin to a close in the greater part of Europe, an that era of recognised laws and separate nationalities which was just beginning t dawn upon the world. William had the characteristics of the daring soldier, the military adventurer, even of the freebooter and the pirate, but he had also those of the statesman, the legislator, and the founder of dynasties. His face and figure commanded attention. He had the height and form of a giant, a stern although handsome face, and enormous strength, with an equal skill in every form of physical exercise. During all his early struggles in Normandy he displayed not only a courage which never could be shaken, but a temperament which seemed to become more composed and calculating as the dangers in his way increased. He had many of the faults common to his times. He was cruel to his enemies, unsparing in his revenge, and often ordered the infliction of tortures the mere description of which would shake the nerves of a modern reader. But as to his undaunted courage and his military capacity there could be no question. It is said that Julius Cæsar could always distinguish, even at the height of some hotly-contested battle, what it was possible for him to accomplish and what would be impossible. William seems to have had much of the same quality.

The Battle of Hastings. On the death of Edward the Confessor, in 1066, Harold, the second son of Earl Godwine, claimed the throne, was elected king as Harold II., and crowned in Westminster Abbey. But William of Normandy had by this time resolved to assert his own claims, and was all the more resolved to do so because he believed Harold had at one time urged him to seek the succession. England was invaded by Hardrada, King of Norway, but Harold inflicted a complete defeat on the Norwegian invaders in a battle at which Hardrada was killed. William, however, had yet to come. He landed in England four days after. On October 14th, he defeated Harold in the famous battle at Senlac, a few miles from



WILLIAM THE CONQUEROR GRANTING A CHARTER TO THE CITIZENS OF LONDON

From the Painting in the Royal Exchange by SEYMOUR LUCAS, R.A. [See HISTORY]

NOTE BY THE ARTIST. The scene represented is the moment when the Conqueror, attended by his Queen and surrounded by his bishops and nobles, is handing the charter to Godfrey. The architecture is taken from the Chapel of the Pyx at Westminster, which is generally accepted as having been built before the Norman Conquest; the costume is from the Bayeux Tapestry. SEYMOUR LUCAS.

Hastings. The battle went on from early morning until late evening. William of Normandy was completely victorious, and Harold was killed. William then became King of England, and his position was recognised by the Pope. He had still to put down many uprisings against his rule, and for some years a great part of the country was devastated by war; but in 1070 the conquest was complete. In 1087 William was engaged in a war with Philip I. of France, and during the course of the war he had Mantes, a small French town, burned. While he was riding through the burning town to see that his commands were carried out, his horse stumbled, and he was flung to the ground, receiving injuries from which he died at Rouen, on the 9th September, 1087. Thus perished by a commonplace, or even an inglorious, accident, one of the greatest soldiers and commanders of early history.

The Beginning of Feudalism. The reign of William imposed upon England a feudal constitution. The old national assembly of the realm was converted into a council of the sovereign's tenants-in-chief, all title to land being derived from the King's grant. Domesday Book, or Doomesday Book, was one of the products of King William's reign; it was, at least, begun under his authority, and was intended as a register to determine the right to the tenure of estates, to ascertain the quantity of every landowner's due to the State, and the amount of military assistance which each landlord was bound to render to his sovereign in case of need. The book is still preserved in the Public Record Office, and consists of two volumes, one large and one small. The survey which it proposed to make was enlarged at later periods, and the taxes were levied according to its system down to the reign of King Henry VIII., when a new survey was taken and many alterations in taxation were made.

William may be said to have introduced into England the feudal system which had been practised from earlier times in Germany and France, and must have been in operation in one form or another during the earlier formation of most states. According to the principle established by William, the kingdom was divided into Baronies, which were given by the sovereign on the express condition that each holder should supply the king with men and money for warlike enterprise. William became entangled in many troubles with the Barons, because, although they cordially approved of that part of the system which made the vassals who held land under them bound to pay for their land in personal military service as well as in money, they did not approve of the development which William was giving to it. The purpose of the sovereign was to convert the whole State system into feudalism, with the King as supreme head, and the nobles as his vassals, just as the lower orders of the landowners were to be the vassals of the nobles. The result was that William was met with serious resistance here and there by the Barons, and at one period there seemed to be a national crisis at hand. The King's strong will and great intellectual resources made him triumphant, however, and he became the supreme power in the State. He exercised control even over the Church, and decreed that no excommunication could be issued without licence from the sovereign, nor could any synod legislate without his assent.

The Jews in England. One important effect of William's reign and its policy was the settlement in England of a vast number of Jewish traders, whom he encouraged and enabled by his protection to find homes in England. The Jew was then, as Mr. Green puts it, "the only capitalist in Europe," and the spending of his money gave an impulse to the manufactures and the industry of his new home. The money of the Jews helped the King frequently in his struggles against his rebellious Barons. The Jews were not treated as citizens nor as having any of the civil rights, such as these were, which belonged to the Christians; but they were allowed to conduct their business in Britain, and the Christians had no hesitation in getting all the benefit they could from their money. The story of the treatment of the Jews in England is not one which can be read all through with much satisfaction by English students, but William, who first encouraged their settlement in England, dealt much more fairly with them than did many of his successors. William the Conqueror was, indeed, a man in advance of his age. He was, according to his lights, a reformer as well as a great soldier, and most of his errors and wrongdoing belonged to his period rather than to himself. His reign opened a new era in the history of England.

SHEEP AND PIGS

Short-woolled, Long-woolled, and Hill Country Breeds. Management and Breeding. Shearing. Breeds of Pigs. Building of Sties. Feeding

By Professor JAMES LONG

SHEEP

Great Britain is extremely rich in its breeds of sheep, which are usually classified as Short-wools and Long-wools; the latter, however, may consistently be divided, the mountain breeds being separately distinguished. British sheep are chiefly produced for the butcher, but some of our important breeds not only grow abundant, but fine and valuable wool, and although the market price of this commodity is now low, breeders continue to take pains in the selection of their stock with the object of maintaining the quality of the fleece as well as the form of the animal and the quality and the quantity of its meat. There has long been a tendency to produce mutton of excessive fatness, and this is largely owing to public competitions, but since the introduction of the carcase competition at the London Smithfield Show, and the revelations which have accompanied it, great pains have been taken by the judges to discount excessive fatness and to encourage breeders to produce mutton more suitable to the requirements of the market by the increase of the lean meat on the best parts of the carcase and the reduction of the amount of fat. From year to year have we noticed in examining this splendid display that many of the animals which were awarded prizes when alive were so imperfect in the carcase that the thickness of the fat over the loin reached as much as two inches.

A THREE-SHEAR TUP

Adaptation of Breed to Environment. The importance of breed in the maintenance and prosperity of a flock can scarcely be overestimated. Some varieties are suitable, like the Southdown, to the chalk hills of Sussex or Hampshire; others to the lowlands of the Midland and other counties; others, again, to the mountains of the North; or, like the Romney Marsh breed, to low-lying, wet land, which encourages foot-rot and other diseases in those classes of sheep which, owing to heredity and constitution, are unsuited to soils of this class. Our principal varieties are remarkable for their massive form or their symmetry; but we must not be entirely guided by what we see at livestock exhibitions, for the perfection of form which so many animals present is often owing to the skill of the shepherd in his manipulation of the wool with the shears. Depth, width, and the finer lines of form are constantly imparted by this somewhat improper and mistaken practice. Nor can we acquit some exhibitors of going still further, for where colour is a point with the judges, portions of white wool are constantly removed from among the black on the face or forehead—as we have personally witnessed—with no other object than that of gaining a prize. Many varieties of sheep, too, are coloured with ochre of different tints, so that the visitor to a show may fail to recognise in some exhibits the name of a breed which has thus been disfigured.

The Names at Various Ages. Sheep, according to their sex and age, are known by different names in different localities. Thus, the male lamb is first known as a ram or tup-lamb; subsequently as a yearling or shearling ram, or tup, after his first fleece has been removed. After a second shearing, he becomes a two-shear ram, or tup. A male sheep, too, which has been castrated, is known as a wether lamb, a wether hogg, a tegg, or a hogget, until his first shearing. After the clipping of the first fleece the male sheep is known as a wether or shearling wether; while after the second clip he is described as a two-shear wether. Two-shear wethers are, however, seldom, if ever, exhibited at our fat-stock shows, the tendency being to feed for the butcher before the second shearing season; and for this reason, except for the necessary ultimate feeding of tups and ewes for consumption, almost all British mutton is now young and tender. The female lamb is known as a ewe-lamb; next as a ewe, or hogget, or ewe-hogget, and after a first clipping as a theave, or gimmer, or shearling ewe. In some districts, however, the young ewe is described as a "tuttuth," or a two-tooth; after the appearance of the second pair of permanent incisors, she is known as a four-toothed, subsequently as a six-toothed, and lastly, when the eight incisors have all appeared, as a full-mouthed ewe. When these teeth commence to fall, the ewe is known as a broken-mouthed ewe, and her value for breeding stock or mutton has diminished. Indeed, the money value of a sheep declines, except in particular instances, when she has grown six permanent incisors.

SHORT-WOOLLED SHEEP

The Southdown. Not only is the Southdown, with which his Majesty the King has been so successful, the most perfect in quality, form, and character, of any of our native breeds, but it is the one variety which has been employed with marked success in the creation of several other short-woolled breeds. It is a small sheep, compact, small-headed, and short-legged, and covered with fine, close wool. It is rather dark faced, produces the finest of meat, and is employed for crossing purposes with the greatest success. Its home is the Sussex Downs, but it is bred by a large number of flockmasters, professional and amateur alike, on dry lowlands, for it is not suitable to land of a wet character.

SHROPSHIRE RAM

The Shropshire. Somewhat similar in type and form to the Southdown, but slightly larger, the Shropshire owes much of its existence to the Royal breed. It possesses a dark face, ears, and legs, the face being remarkably woolled; it produces splendid meat, and is now used very largely in crossing for the improvement of inferior breeds or mixed flocks. No variety is, perhaps, so largely exhibited, and none have been so quickly perfected. It is adapted to almost any climate, inasmuch as it is hardy and prolific, and is approached in character, form, or quality by very few of our native breeds.

The Oxford. Sometimes known as the *Oxford Down*, this is a massive, short-woolled sheep, larger and coarser than the Shropshire, with dark-brown face and legs, excellent form, and a thick, useful fleece. It produces fine early lambs, and is largely bred in parts of the Midlands and South-West of England. It owes its character to the blood of the Cotswold, the Hampshire, and the Southdown.

The Hampshire Down. Bearing some resemblance to the Oxford, the Hampshire Down is also a large, somewhat coarse and massive sheep, with very dark face and legs, and is chiefly bred in Hampshire and Wiltshire, although, like the Oxford, it is a favourite with many outside flockmasters. It produces a big early lamb, which quickly runs into money, makes a most excellent cross, and owes much of its quality and the splendid flavour of its meat to the Southdown.

The Suffolk. A newly-improved breed which also owes something to the Southdown, the Suffolk has been brought rapidly to the front by a few skilled breeders, who maintain the somewhat dense blackness of its face, ears, and legs. No sheep has shown better quality in the carcase competitions; owing to the comparative largeness of the quantity of lean it produces and the smallness of fat on the best parts of the carcase it is invaluable. It resembles the Oxford and the Hampshire in size, and is covered with fine, close wool. The Suffolk is a hardy and prolific variety.

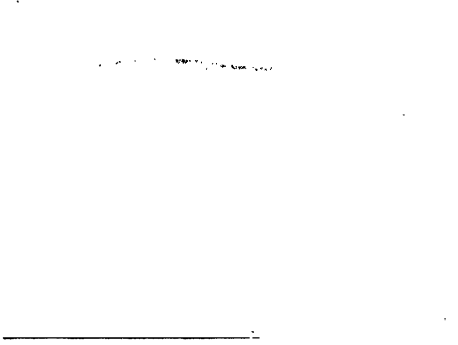
The Dorset Horn. The most remarkable of all English breeds for its early prolificacy and its Christmas lamb is the Dorset Horn [page 257]. Indeed, we may say more—it is associated with the production of two crops of lambs in the same year, although there are doubts as to the wisdom of the practice of breeding so rapidly. It is a sheep of average size, for it takes a medium position between the heavier long-wools, such as the Lincoln and the Leicester, and the mountain breeds of the North and West. Its fleece is close, and of medium length, the head carrying a forelock. Although the Dorset is chiefly bred in Dorset and Somerset, it is fancied by many flockmasters in other parts of England.

The Ryeland. A white-faced breed of long standing, resembling the Dorset in size, the Ryeland produces good meat, but shorter wool, of fine quality. It is not largely bred, and is, indeed, little known out of Herefordshire and neighbourhood, its place being more or less taken by the Shropshire, which produces a better cross. Like the Dorset, it is adorned with a forelock.

LONG-WOOLLED SHEEP

Lincolns. The Lincoln [page 257] is the largest and heaviest sheep grown in these islands, probably in the world. Although with us it is chiefly confined to Lincolnshire, numbers are exported for the improvement of foreign and Colonial flocks, the breed being hardy, the feet sound, the fleece very heavy—reaching up to 15 lb.—and the wool of high quality. The joints, however, are large, the sheep being easily fattened. A ram of this breed has reached 1,000 guineas under the hammer, so much is it valued for export. The Lincoln owes much to the blood of the Leicester, which is an older variety, both face and feet being white.

The Leicester. The old-established breed, the Leicester [page 258], which is the foundation of many British varieties, was produced by the famous Robert Bakewell, at a time when British sheep, like British cattle, were in the making. Though slightly smaller than the Lincoln, it is a large sheep, with white feet and legs, covered with wool of good quality, and producing meat which is neither so close nor so fat as that of some other breeds, although it is easily fattened. The Leicester is much used for crossing purposes, and may be regarded as the progenitor of the Border Leicester and the Wensleydale, which are, practically speaking, collateral branches of Bakewell's handiwork. The Leicester, which is known as the Dishley in France, is largely kept in the Midlands, either pure or in flocks of the Leicester type, and right up to the Scottish Border.



DEVON LONG-WOOL RAM

The Border Leicester. This variety, much admired, bred, and exhibited by Mr. Arthur Balfour, is a handsome, hardy sheep, with open, curly wool, and most prolific as a breeder. It stands rather high on its legs, but is smart in appearance, and carries a sharply-cut typical head. It is bred largely in the Border counties, and is in great demand for crossing purposes in Scotland.

Cotswolds. The most striking and handsome of all British varieties is, perhaps, the Cotswold. These sheep are chiefly bred on the Cotswold Hills, are very large in size, covered with a brilliant white curly fleece, and have white faces and legs. The joints reach almost as heavy a weight as those of the Lincoln, but they are somewhat coarse and fat, the carcases reaching great size. The Cotswold makes an excellent cross.

Kent, or Romney Marsh. The Kent, or Romney Marsh breed is a big, massive animal, with white legs and face, a black nose, and plenty of wool of most excellent quality. It is especially hardy and suitable for those districts where foot-rot is most easily acquired, for it maintains its feet in sound condition with but little attention. It is largely kept on the marshes of Kent, and owes a great deal to the Leicester blood which runs in its veins.

The Devon Long-wool. Chiefly bred in Devon, West Somerset, and Cornwall, like so many other local breeds the Devon Long-wool has been immensely improved by crossing with the Leicester. It has a white face and legs, an attractive forelock, fine wool, and a weighty carcase, although the meat is rather coarse. There is a local variety known as the South Devon, the legs and faces of which are dark, but the fleece is handsome, and the wool silky in texture.

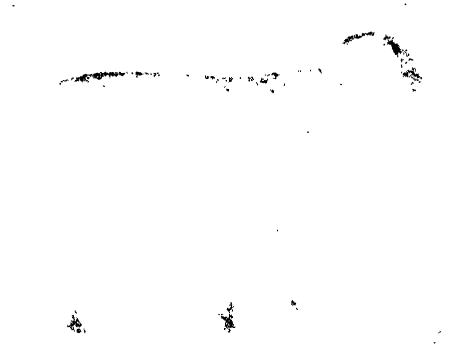
Wensleydale. This variety, which is in large part a descendant of the Leicester, to which it owes so much of its character, both direct and through the Teeswater branch, is kept in the famous Yorkshire dale after which it is named. It is dark-faced, with a forelock, and carries a fine, curly fleece. The blue skin is a characteristic of the breed, and enables the amateur to select it with unusual ease. The Wensleydale is extremely handsome, well built, and produces good meat.

Roscommon. This is practically the only pure breed of sheep peculiar to Ireland. It is large, covered with a heavy fleece of fine, silky wool, and is a producer of most excellent meat. It is handsomely formed, although in this respect it falls short of the best English varieties, to which in many cases it is first cousin, owing to the blood which has been imparted to it by the famous Leicester.

HILL COUNTRY BREEDS

The Black Faced. This is a characteristic and most picturesque Highland sheep, hardy, with black or mottled face and legs, and curly or spiral horns. The carcase is small, and the wool very long, open, coarse, and shaggy. The Black Faced is often brought into England for feeding into mutton, but is a persistent wanderer, breaking through hedges with ease, and hence it is unsuitable for small farms. It is believed to be a pure race, but crosses well, and makes excellent mutton, although the joints are small.

The Lonk. This variety closely resembles the Black Faced in appearance, especially in face, horn, and the length and character of its wool, but it is larger in size, and chiefly bred in the hills of East Lancashire and West Yorkshire. It is extremely handsome.



WENSLEYDALE RAM

The Cheviot. This is a medium-sized sheep, with white face and legs, and a very characteristic Roman-shaped nose. The fleece is of medium length, and the wool close, but the carcase is not sufficiently square and compact. It is chiefly bred in the Lowlands of the North.

The Limestone Variety. The Limestone is a white-faced, horned, fine-woolled sheep, somewhat over medium size, very hardy, and is kept in the district of the North-West of England.

The Herdwick. A breed of somewhat uncertain lineage, found in the hill countries of Cumberland and Westmorland, the Herdwick carries a white fleece, the wool being coarse, somewhat hairy, and sometimes spotted. There may or may not be horns.

The Welsh. This is a small variety, producing very finely-flavoured mutton. The joints are quite small and much esteemed. The face is white, and the wool fine and soft. Occasionally Welsh sheep are horned.

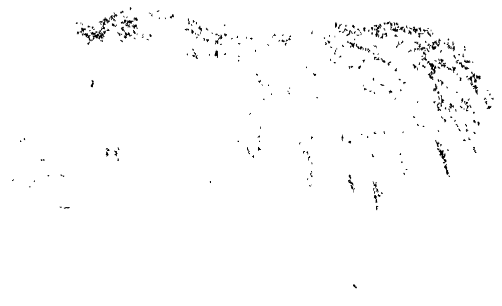
The Exmoor and Dartmoor. Bred in the Devonshire hills, the Exmoor is a horned, white-faced sheep, quite hardy, and carrying a short, close, soft-woolled fleece. Although it is not well-formed—wanting in squareness—it crosses well, and produces excellent mutton. The Dartmoor breed [page 258], which is quite distinct, is larger than the Exmoor, also quite hardy, with white face and legs, and long, soft wool. The carcase is of medium size, and the meat of high quality; the breed stands much exposure.

The Clun, or Radnor Forest. This is a local variety of sheep, found in Shropshire and adjacent Welsh districts. It is descended from an ancient breed with a tanned face, of which it still shows something in the tinge of the mottled face of to-day. It has been improved by crossing with the Shropshire. The wool is rather coarse, but the mutton is of excellent quality.

MANAGEMENT OF SHEEP

Rearing and Feeding. In the British Islands sheep are chiefly bred for mutton, and as the public taste is decidedly in favour of lean meat, the flockmaster should take special pains in the selection of his breeding stock and in the arrangement of his rations. The sheep usually exhibited at our "fat-stock" shows are excessively fat, from two to three inches being frequently found upon the back and loin, while the oyster part, or lean of the mutton chop, is relatively small. The loin indeed should be much leaner, and the remark applies to every joint of the carcase. The waste on the saddle, neck, and leg is frequently so considerable in ordinary butcher's meat that the cost of the edible portion is quite doubled. Although wool takes a second place, the skilful breeder, in selecting his breeding flock, will take care to reject ewes with coarse, hairy, or wiry wool, and to retain those which carry the heaviest fleece of wool of fine quality.

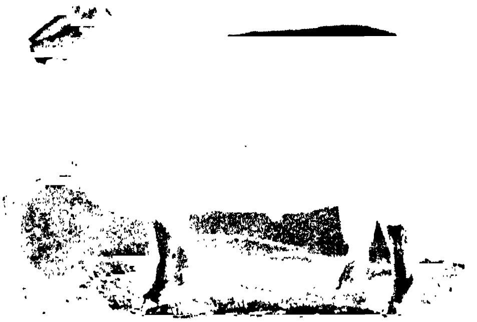
Selecting Breeding Rams. In the selection of the breeding rams, it is important to secure constitution, vigour, form, well-shaped legs, broad and deep loins, width behind the shoulders, neat heads, and heavy, but fine fleeces. In practice, the type or breed of sheep selected is that best suited to the district. This especially applies to low-lying, or damp soils, and high-lying, or uplands. From year to year fresh pedigreed rams and ram lambs should be selected, two to every hundred ewes. By adopting this practice, and by systematically rejecting inferior or weakly ewes, a flock may be gradually built up, as well in character as in quality, size, and constitution. It is important that the ewe should have a large, perfect udder, or she may not be able to rear her lambs, especially when she bears twins. The ewe should be young, possessing not more than four permanent incisor teeth; indeed, in a breeding flock, it is wise to sell the ewes before or by the time sixth teeth have appeared. They should never be kept, special circumstances excepted, until they have become broken-mouthed.



SHEARLING BLACK FACE

Care of the Breeding Flock. The breeding flock should always be kept in good, but not fat condition. Early maturity is the order of the day; and that lambs may grow well and be ready for an early market, the ewe should be kept in such a condition that she will supply abundant milk to provide for their sustenance and rapid growth. In the South of England rams are mated with the ewes about the first of September, while the further we go North, the later the date selected. At this time the ewes may receive a liberal ration, say, three-quarters of a pound of decorticated cotton-cake, or a mixture of this cake with bran or oats. The practice not only assists in improving the general condition, but is almost universally believed to influence the number of twins, which is a great point. In Dorset, as with many breeders of the Dorset horned sheep, it is customary to produce lambs for Christmas; while in the adjoining county of Hampshire, lambs of the Hampshire Down flock come next into the market.

Management of a Flock. A great deal of forethought is needed in the management of a breeding flock. It is imperative, for example, to arrange earlier in the year where sheepfolds for use in the lambing season should be built, and consequently where hay and straw stacks should be erected, for the one should be contiguous to the other. The stacks may be arranged two or three together, to form shelters, the folds being constructed close to them, and on the warmer side. In this way straw for covering the pens, for providing shelter around the hurdles, and for littering the inside of the fold is easily obtainable. Sheep at all times require some form of protection, but never so much as during the lambing season. The ewes lamb with ease, but where difficulties arise, and the shepherd's help becomes necessary, he should be required to anoint his hands—and this is really imperative—with carbolised oil, to prevent the conveyance of infectious germs, and the possible death of the ewe. After lambing, the ewe and her single, twins, or triplets, should be placed in one of the small lambing-pens erected with hurdles under cover, and within the fold. The form of the sheep-hurdle differs in accordance with the district and the material grown for its manufacture. In many cases, wattle hurdles, made of hazel, are constructed on the farm. In others, open gate-hurdles are made of split ash; in others, hurdles of similar form, with pointed feet, and made of sawn common deal, are purchased from a manufacturer. The average hurdle is fixed to a pair of pointed stakes driven into the ground with a beetle, the two being linked together with an oval iron ring. For protection in severe weather a fold may be enclosed by two sets of hurdles or wattles, placed close together, with straw between.



ROSCOMMON RAM

Weaning Lambs. Lambs are usually dropped at the end of five months, or from 140 to 150 days, but the actual period of gestation varies from 140 to 151 days. Professor Henry's observations of the flock of 500 ewes on the Wisconsin Experiment Farm point to 146 to 149 days on which the largest number and the strongest lambs were dropped. The actual range was from 145 to 149 days, although in odd cases the extremes of 140 and 151 days were reached. The sex of the lambs appeared to make no difference, but it is believed that early maturity has reduced the period of pregnancy. The majority should be twins, but many singles appear, and sometimes triplets. Twin lambs weigh nearly or quite as much as singles, from 8 lb. to 18 lb. at birth, in accordance with the breed and the condition in which the ewe has been maintained. The males weigh slightly more than the females. The lambs are weaned at from 12 to 24 weeks old, having been well fed from birth, both through the ewe and from the trough, after trough-feeding has commenced. On arable sheep-farms the breeding flock is placed upon turnips or swedes, the latter being still on the ground. On the forward side of the fold, lamb creeps, or gates, through which the lambs can pass but not the ewes, are fixed between the hurdles, and thus the lambs are able to go forward and nibble the younger portion of the tops of the roots, and to feed from troughs provided with special rations of linseed cake, crushed oats and bran, or some similarly useful food. On the following day the fold is moved forward, the ewes consuming what the lambs have left, while the lambs again go forward among the fresh roots. At the same time the ewes are provided with food, three-quarters to one pound a day, composed of cake, crushed oats or bran, crushed maize, malt coombs, a few crushed beans, and hay chaff, with long hay placed in specially made racks. Similar arrangements may be made on grass land, if necessary; but usually the flock, ewes and lambs alike, are liberty, and changed from field to field as the herbage becomes scarce and the ground soiled. The ram lambs are castrated at from 10 to 14 days old. Where the removal of the tail is customary, it is cut a little earlier, so that the two operations are not carried out at the same time. In either case it is well to avoid severe frosty weather.

Avoidance of Wet Land. As forage crops come in—vetches, rape, sainfoin, clover, and cabbage—the flock is folded upon them, as in the case of the turnip and the swede, but no sudden change should be made from one food to another, the introduction to the new food being gradual. It is important to remember that wet land is bad for both ewes and lambs, introducing both foot-rot and fluke, a disease of the liver. Ailing ewes or lambs should be examined immediately their condition is in the least abnormal. Foot-rot is contagious, and affected sheep should be at once removed, and the feet pared and dressed with a lotion or ointment obtainable of any druggist. A well-managed flock in which foot-rot ever exists should be occasionally driven through a trough slightly filled with a solution intended to maintain the feet free from any taint of the disease. Wet grassland should be avoided at any cost, sheep frequently consuming organisms which cause scour, sickness, and death. Nor should any sheep be introduced which has been in contact with sheep suffering

from scab, the most foul and destructive of the complaints of the flock.

Food for the Flock. Arrangements for the production of food for the flock should be made long before it is required. The area sown for its consumption will depend upon the number of animals retained and the number of lambs expected. On the arable farm these crops will be grown upon land which is fairly dry in a wet season—i.e., through which the rain easily passes. A good shepherd will, in making this arrangement, be a great help to his employer. He is usually a lover of his flock, and will think of points which may escape his master. The shepherd is always anxious for the sheep to thrive, hence he is almost certain to provide for the best, and to supply his charges with all the hay and grain he can obtain in reason. While the ewes are with the lambs, as already observed, they may obtain from ¾ lb. to 1 lb. of cake and grain daily, both being crushed, the finer portion of the cake going to the lambs together with 1 lb. of hay, part of which will be cut into chaff. As green foods come in the hay will be reduced, and when the ewes are receiving vetches, clover, or sainfoin, or, indeed, any leguminous foods, the cakes and beans supplied in the troughs may be reduced also, and the carbonaceous foods, such as crushed maize or barley, slightly increased. At the same time the ewes may receive slightly less corn and cake, and the lambs more. The wether lambs should be better fed than the ewe-lambs, and pushed on for market, the latter being kept for stock, with the exception of those which are rejected, which should be fed for the butcher with the wethers. Through the summer ewes and lambs may be kept on dry pastures, except when forage crops are provided, but always fed for the maintenance of good condition. As the harvest fields are cleared, they will be taken on to the stubbles, which they will clear of weeds and stray ears of corn. The growth of successive green crops, roots and cabbage, is all-important on the arable sheep-farm. For the older ewes, and especially those which are broken-mouthed, swedes, when supplied, may be sliced daily. Salt should always be provided, and where there are no ponds, water fetched and kept handy in troughs.

Dipping. Sheep are dipped for the purpose of destroying parasites, some of which are dangerous to health and life, while others prevent thriftiness. Dip mixtures may be made on the farm or purchased of manufacturers. The latter plan is strongly recommended as the simplest, safest, and best. Information as to the most successful preparation is easily obtainable from experienced flockmasters. Home-made dips are prepared by the admixture of arsenic, carbolic acid, soda, and soft-soap, but owing to the dangerous character of the two poisons, we strongly suggest that they should be left alone. The dip being mixed with water in accordance with the instructions of the maker, and placed in a tub of sufficient size, the sheep may be lifted in one by one, the whole body, the head excepted, being kept under at least a minute, and this should be timed by the farmer, watch in hand. Mechanical dipping-vessels are made which simplify and reduce the labour of handling, which is considerable, but there is no surer and safer plan than that of hand dipping as suggested. The beginner will do well to witness both methods, and choose for himself. Dipping is seldom practised more than once a year, but it should be performed twice to keep the flock perfectly safe. Efforts are being made to pass a law rendering sheep-dipping compulsory, in consequence of the many dangerous and costly outbreaks of sheepscab.

Clipping. Before the annual sheep-shearing, the whole flock should be well washed, a fine sunny day being selected a week to a fortnight before the removal of the fleeces. The process removes the "suint"—a material excreted from the skin which forms from one-sixth to more than one-third of the weight of the wool—and much of the fatty matter of the wool, which also adds largely to its weight, with the result that washed fleece weighs less than the unwashed fleece, the former realising a higher price per lb. Owing, however, to the trouble involved, many flockmasters have abandoned washing, regarding the increased weight of the wool "in the grease," as it is termed, as an equivalent to the loss of price per lb. Clipping is annually performed by hand, although mechanical clipping-machines are employed by many large flockmasters. On large sheep-farms the shepherd and his assistant, sometimes with help, carry out the work, but generally small gangs of men travel a district and shear the flocks for their owners at so much per score. The wool is usually sold to a dealer on the basis of market price. Sometimes, however, large farmers make a practice of buying the clippings of small flockmasters, and consigning them with their own to the great buyers of the North. The value of the wool not only depends upon its condition—whether washed or unwashed—but upon the breed and the smallness of the fibre, which varies very much in diameter. The best wool grows upon the back and neck, the inferior upon the belly. The clippings of the short-woolled breeds contain the most fatty matter. [See TEXTILES, page 1120.]

In judging sheep, form, size, and quality of wool are chiefly taken into consideration. Where the colour of the face and legs forms a point, this also is considered. It is, however, a common practice amongst shepherds to clip sheep before exhibition in order to give them compactness, massiveness, and symmetry. The time has arrived, however, when important prizes should be withheld from exhibits so manipulated, and it will be well when committees of great exhibitions provide for the removal of the fleece of the competitors for breed cups and champion prizes. This plan has been adopted in France with great advantage.

Age. Sheep have 32 teeth, eight being incisors, none of which are in the upper jaw. The temporary incisors are well up at the end of four weeks, and the permanent incisors at the end of three years. The first permanent incisors to appear are the centrals, at the end of a year; the second pair at a year and a half, right and left of the first pair; and the third pair at two and a quarter years. According to the Smithfield regulations, where the central permanent incisors are cut, the animals are considered as exceeding 10 months, and where they are fully up, as exceeding 12 months old. When the third pair of permanent incisors are cut, the sheep are regarded as exceeding 19 months, and when fully up as exceeding 24 months, if the temporary molars have been shed. Where the fourth, or corner, pair of permanent incisors are well up and show marks of wear, sheep are regarded as exceeding three years old.

Weights of Sheep. On the basis of the weights of sheep exhibited annually at Smithfield Show, lambs gain from 8 oz. to 11¾ oz. per day from birth, and wethers under two years from 3¾ to 8 oz., in each case depending upon the breed and the system of feeding adopted. Show sheep thus gain unusual weights. The heaviest sheep are the Lincolns, Cotswolds, Leicesters, Kents, Suffolks, Hampshires, and Oxfords, and these, as a rule, make the heaviest daily gains in weight. The butcher's carcase of a sheep weighs from 50 to 60 per cent. of the weight of the live animal, depending on its condition, whether lean, half-fat, or fat, and whether the fleece has been removed or not.

PIGS

The entire male pig is known as a boar, a brawn, or a hog. When cut, or castrated, he is described as a hog, a shott, or a store. The young female is known—and the term varies with the district—as a gilt, yelt, or elt. After having produced young, she becomes a sow, and if cut for the removal of the ovary, which enables her to feed for weight more rapidly, she is a spayed sow. The young family of a sow is known as a "litter," or "farrow," while parturition, or giving birth to her young, is recognised as farrowing, or littering.

The Large White Breed. This variety, which is the finest in existence, and one which has been largely exported for the improvement of swine in all parts of the world, is the result of skill and selection at the hands of English breeders. Although a white pig, it is occasionally found with black spots or patches. The head, although long, is really of medium length considering the size of the animal, the snout being slightly inclined upwards. There is great width between the eyes, the ears are large, carried forward, and slightly drooping. The neck is comparatively fine, and the collar, the meat of which is inferior, medium. The shoulders are strong and broad, the back straight, and of great length; the ribs are rather flat, and there is plenty of width of loin and thickness behind the shoulder, giving the heart plenty of room. The tail is set high, and is fine and curly. The hams are large, and the legs of medium length. In many animals the hair is very fine and scanty, but it should be fairly abundant, silky, and strong. The Large Whites reach great weights and enormous size. The young pigs are large at birth, and grow rapidly, but they do not fatten so easily as the Middle Whites or Berkshires at this stage. The meat is of first rate quality, and carries a larger proportion of lean to fat than the Middle or Small Whites. Good strains have fine constitutions and produce large litters. Many white pigs are described as of the large breed without any claim to this designation, although they are sometimes quite pure. Breeders and feeders too frequently sell animals for breeding stock which are mere mongrels, or which are the wasters or culls selected from their litters. The home of the Large White pig is Yorkshire and Lancashire, but it is now bred in all parts of the country.

The Middle Whites. This breed is the produce of a cross between the Large and the Small White, all three breeds having formerly been known as Yorkshires. Its size is about midway between the Small and the Large, and its purity is often determined by the form of its head, which is below medium in length, with a short turned-up snout, a broad face, ears of medium length carried slightly forward, a heavy, fatty collar, and a body which is deep, thick, and compact. The back is straight and broad, there is plenty of depth through the heart, a wide loin and heavy hams, placed on rather short, straight legs. The Middle White fattens rapidly, but it produces meat which carries too much fat in proportion to its lean. It is, however, excellent for crossing, especially if a well-bred boar is used on large, lengthy, lean sows which are not well bred. The hair is plentiful, strong, and silky, and the tail curly and carried rather high. The Middle White pig is bred in all parts of the country, but cannot be recommended with such confidence as the Large White.

The Small White. This variety, which has long been established, is, practically speaking, a fancy pig, more suitable for the amusement of the amateur than for utilitarian purposes. It is too small either for the production of profitable porkers or useful sides of bacon. Its growth is slow, although it puts on fat with rapidity, while its meat contains far too much fat in proportion to lean. The body is chubby and carried on short legs. The face is small, the snout short and turned-up—a great point in the breed as an exhibition animal—the ears are small and almost erect, the collar heavy, the tail set on high, and the hair abundant, strong, and usually wavy or even curly. The breed cannot be recommended for profitable purposes whether in its pure form or as a cross.

The Large Black. This breed is promoted by the Large Black Pig Society, which was established in 1898, and which has adopted a shield as a trade mark. The variety, which is largely bred in Devon and Cornwall, Essex and Suffolk, as well as in many other parts of England, is of gentle disposition, a good pasturer, a good feeder, and of undisputed merit as a utilitarian animal. The following description of the points of the breed are taken from the "Book of the Pig."*

"Head, medium length, and wide between the ears; ears, long, thin, and inclined well over the face; jowl, medium size; neck, fairly long and muscular; chest, wide and deep; shoulders, oblique, with narrow plate; back, long and level (rising a little to centre of back not objected to); sides, very deep; ribs, well-sprung; loin, broad; quarters, long, wide, and not drooping; hams, large and well-filled to hocks; tail, set high and not coarse; legs, short and straight; belly and flank, thick and well-filled; skin, fine and soft; coat, moderate quantity of straight, silky hair. Objections: head, narrow forehead or 'dished nose'; ears, thick, coarse, or pricked; coat, coarse or curly, bristly mane. Disqualification: any other colour than black."

Not only are great weights reached by the Large Black, but as the table which appears in this lesson will show, the variety puts on great weight per day during its earlier years. The proportion of lean to fat is large, possibly as large as in any other variety of pig, while the inferior parts of the carcase are relatively light.

The Small Black. The Small Black pig is now little bred, while it has been entirely removed from the list of exhibition pigs. It was formerly known as the Black Essex, Suffolk, and Dorset. Although once larger than the Small White, it is almost identical with it in form, character, and quality; the face, however, was never so short nor so characteristic as that of the Small White breed. In other respects, to describe the one is to describe the other. It is not a farmer's pig. The hair is abundant and strong, although silky. The meat is too fat, the growth slow, and the variety, although gradually dying out as a pure breed, has been to some extent employed in building up the Large Black, which is so much superior for economical purposes that the small variety is not again likely to take a prominent place.

The Berkshires. This is still the chief of the Black breeds, although the pure Berkshire pig has white points,—*i.e.*, there is a white blaze on the face, white feet, and a white tip to the tail. The variety is hardy, prolific, a producer of first-class meat, which is sufficiently lean for the public taste and very popular in all parts of the country. At the exhibitions the Berkshire classes are more extensively filled than those of any other variety. The head is of medium length, the face slightly dished, the neck of medium size, the back straight, the shoulders well developed, the loin broad, the body deep, providing good sides or flitches of bacon, the hams well developed, and the legs of medium length. The skin is less of a dead black than that of the other Black breeds, many strains presenting a plum-coloured tinge. The hair is medium in quantity, but occasionally too coarse. No variety of pig is more symmetrical, especially when fattened for the great winter exhibitions.

The Tamworth. This is one of the oldest breeds of British pig, and it has been much less crossed for improvement by Neapolitan and other imported swine, which were used in the manufacture of the Whites and Small Blacks. The Tamworth, which is chiefly kept in the counties of Stafford and Warwick, is of a bright sandy colour, although usually described as red. The brilliancy of the tint changes with age, and becomes rusty or sandy grey, the skin being sometimes patched or spotted. The Tamworth is hardy, of great length, and provided with excellent sides. The head is long and the face comparatively narrow; the ears are large, the neck fine, the back straight, the body deep, the shoulders and loins well developed, and the meat well furnished with lean. The poorest parts of the carcase, as the collar, are not so fully developed as in the breeds already named. Although the Tamworth is one of the very best varieties for economical purposes, it is much less generally kept, and yet it is a prolific, vigorous, and highly valuable pig. In form, it is not equal to the Whites or the Berkshire pigs, but it grows to large size, is easily fed for the butcher, and carries little waste.

Breeding. In the breeding of swine, it is essential to provide for size, rapid growth, without excess of fat, and good constitution. It is also important in the selection of parent stock to ensure stamina in the progeny and large, healthy litters. The sow should be of known healthy, fast-growing, and fast-feeding stock. She should be large, for upon her the size of the young depend in greater measure than on the sire. She should be provided with 12 teats, and produce plenty of milk for the nourishment of her little family. It is important that she should be gentle in disposition. After farrowing, ill-tempered or badly bred sows frequently resent the intrusion of the stockman, and are occasionally apt to wilfully destroy their young. Other sows become careless and indifferent to their litters, and frequently lie upon and crush them, for which reason it is important that in a littering sty a rail should be erected some eight or nine inches from the wall on either side. The selected sire should possess fine points rather than great size, for his influence in imparting quality, colour, symmetry, and type of head, is much greater than that of the dam. He should, moreover, by his possession of super-excellent qualifications on those points in which the female is deficient be expected to counteract the dam's deficiency. A heavy boar is undesirable, but while he should be of full quality, there should be no excessive aptitude to fatten rapidly.

---

* "Book of the Pig," by James Long. (Upcott Gill.)

LARGE BLACK SOW

Purchasing Stock. In the purchase of young stock for breeding purposes, there is no better plan than that of making a selection at one of the large exhibitions, where the best pigs are shown, and thus ensuring not only purity, but quality and size, where size is needed. It may be necessary to pay a high price, but this is as nothing compared with the losses which may follow the purchase of badly bred or inferior animals. This method is one of the few which really ensures the acquisition of reliable breeding stock. The sow, if born early in the year—as she should be—should be served in order to obtain her first litter of the year at an early date, and thus to ensure two litters annually. She is pregnant four months, or about 120 days at the outside, while she comes into season every three weeks. Thus, if she remains with her litter for eight weeks, slightly more or less, a period of a week only can intervene between weaning and the commencement of breeding for the second litter of the year if service has not obtained while she is with her young. It is important that the second litter should be born in such time that the young may be weaned and hardened off, as it were, before the arrival of Christmas or severe weather. Thus, if the first litter of the year arrives in the middle of March, and the sow is mated with the boar again about the middle of May, the second litter should be ready for weaning by the middle of November. Pigs born in the spring and weaned as suggested, have the advantage of the summer for exercise and grazing in case they are intended for stock or to run on as stores, both being of great advantage for invigorating the constitution and maintaining a healthy form of growth. On the other hand, pigs entirely restricted to the sty from birth onwards, are quite unfitted for stock purposes; in these days of rapid fattening and maturing, they are better adapted for conversion into meat. The castration of the young boars may follow soon after weaning, care being taken that they are strong and healthy. Once this operation is witnessed, care and pluck will enable any capable man to do it himself. If allowed to reach a more mature age before the pig's castration is performed, it becomes less simple and more severe, the hot iron being necessary, which is not the case when they are quite young. The gilts are sometimes spayed—*i.e.*, their ovaries are removed with the object of expediting the fattening process. This operation, which is severe, needs greater expertness, but in skilful hands few are lost. We do not, however, advise spaying, nor believe it to be necessary, the advantage not being equivalent to the risk involved.

Feeding and Rearing. The object in feeding the pig is the production of meat with sufficient lean to suit the demands of the trade with as much rapidity and on as small a quantity of food as possible. Hence the importance of selecting appropriate stock for the reproduction of young animals which will mature early, and which will not put on an undue proportion of fat; and next the necessity for exercising due care in the arrangement of the rations. Young pigs, while with their dams, should learn to feed upon the middlings which she receives, but before weaning they should be occasionally supplied—if possible, in an adjoining compartment into which they can pass without the sow—with an occasional handful of wheat or barley. While suckling her young, the best food for the sow is middlings, sometimes termed "shorts," "dan," or "randan." This may be supplemented with a few brewers' grains, some roots, and skimmed milk, all assisting in the production of milk for her young. After weaning, the young pigs may still be supplied with the middlings and milk. Good barley meal with the former should be gradually introduced, until barley meal and milk are supplied alone. The best and most economical ration for rapid fattening is barley meal, skimmed milk, and a few boiled potatoes, but it is most important that the meal should be of high quality. Far too often the meal consists of ground imported barley containing too large a proportion of husk and too small a proportion of flour. To this is sometimes added the grindings of the refuse or cleanings of other grains, which are removed in the mill. Many feeders, especially Americans, prefer maize meal to barley meal. Equally good weights are secured by the employment of maize, skimmed milk, and potatoes, but maize affects the quality of the fat, which becomes yellowish and less firm. Where young pigs are intended for rapid fattening for the market, whether as porkers or baconers, they should be supplied with such food as they will consume and clean up; but where they are intended for stock or store purposes—*i.e.*, fattening at a later period—the food supplied may be less in quantity, and consist of a mixture of middlings and barley meal, with just a few roots in winter, and with clover, lucerne, or vetches in summer, or, if they are turned out for exercise—as is advisable in breeding stock—grass, to which they can help themselves in the fields. As pigs are wide foragers and venture far from home, especially in the acorn season, they are liable to commit damage both on the property of their owners and that of his neighbours, hence the importance of fencing small paddocks adjoining the sty occupied by pigs kept for breeding or later feeding. Both breeding and store pigs may receive a few handfuls of beans, peas, wheat, or oats, daily.

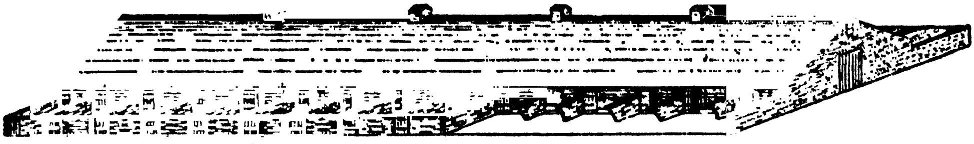
Bacon-curing. In Ireland the bacon cured in the large factories of Limerick, Waterford, and elsewhere is chiefly the production of pigs fed upon potatoes and milk, oftentimes with but little grain; while in Denmark—the greatest bacon-curing country in the world for its size—pigs are largely produced by the aid of skimmed milk from the numerous butter factories, which are in the hands of the farmers. Thus butter and bacon production in these two countries go hand in hand. Maize, when supplied, may be given cooked in the form of meal, but it is questionable whether the cost of cooking is covered by the decreased cost of feeding. Where young pigs, after weaning, are fed with great care and economy, they frequently put on 1 lb. of live weight for every 4 lb. of maize or barley meal consumed. As they grow older week by week, the weight of grain required to produce a pound of live weight is increased, but in feeding porkers and young baconers the quantity of grain consumed should not exceed 5 lb., or thereabouts, per 1 lb. of live weight increase.

The selection of food, like the selection of breeding stock, is of great importance. Pig feeders, who supply important bacon-curing firms, are sometimes paid on the basis of the depth or thickness of the fat upon the back. Where the fat is excessive, the feeder receives a lower price than where it is moderate in quantity; yet, knowing this fact, feeders send pigs to Smithfield and other shows with over 3 in.—sometimes approximating to 4 in.—of fat, a depth which we have actually measured, on their back. Curers, like retailers of fresh pork, prefer what are termed sizeable pigs. Porkers, for example, should not exceed from 100 to 120 lb. in their carcase. Feeding must therefore be arranged on the basis of the buyers' demands, or prices will suffer.

Care of Pigs. Pigs require warm sties in cold weather, otherwise their increase in weight is less rapid. Their sties should, if possible, face the south, the floors may be made either of sparred wood, the interstices just sufficiently wide for the manure and liquid to pass beneath, or they may be of glazed, non-porous brick laid in cement, or of asphalt or concrete. Each floor, where solid, should be made so that the liquid is carried into an outside drain, and the same equally applies to the floors of the outside court leading to the sty. The feeding trough, occasionally built in the wall of the outside court, is better fixed into the partition on the inside of the sty, where a passage leads through the building. It may be of iron, with partitions where several pigs are fed together, or of fireclay. A gate should hang above it so that the attendant by bolting the gate back inside of the trough may supply the food without interruption by the pigs, and then, after having done this, he may swing it towards the passage and bolt it on that side of the trough. In every case it is well to provide a wooden bench in one corner of the sty upon which the pigs may lie perfectly dry and warm, straw being supplied in winter, or whenever necessary, wheat straw being the best, while barley straw should be rigidly excluded. For warmth in winter, straw, loose or in bundles, may be packed over the inside of the sty upon poles laid under the roof. If this is not sufficient, a sliding door may be fitted next to the court to keep out the cold air.

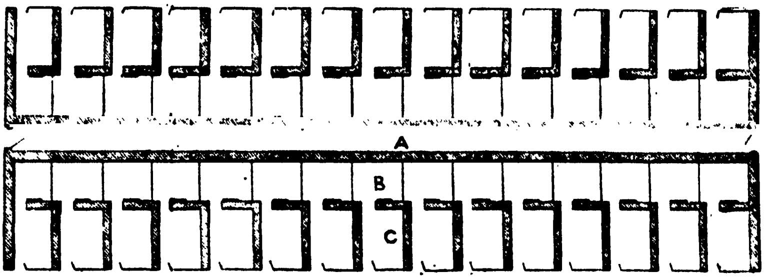
Food for Store Pigs. Pigsties should be solidly built, together with the walls, gates, and partitions, the roof being tiles for warmth in preference to slate or thatch. Pigs should always be supplied with a few coals or cinders, which they consume, and which assists digestion. Sucking pigs are usually sold under three weeks old. After weaning, the sow may still be fed upon middlings, a smaller quantity being given, supplemented by roots, cabbage, small unsalable potatoes, garden refuse, house waste, a few handfuls of grain or beans, some brewers' grains, or if she can be set at liberty, she may be allowed to graze, failing which, in spring and summer, green food may be supplied in the form of clover, vetches, lucerne, or sainfoin. In all cases sows and store pigs may receive in addition to the above foods buttermilk or whey, but meat should never be supplied, although it is a common practice to feed it with liberality in the form of slaughterhouse offal. It is, too, a common practice to turn the pigs of the farm on to the stubbles after harvesting, but its wisdom is questionable. What is saved in food is frequently lost in weight, for by excessive foraging and undue exercise pigs fail to increase in weight. The plan may be adopted in the case of store pigs or breeding sows if no danger of damage to neighbours' property is to be apprehended. Pigs are inveterate rooters, tearing up pastures and meadows unless they are rung, a practice which, unnecessary in the sty-kept pig, is imperative where animals are turned loose. The simplest rings are circular, split, and pointed at one end. They are fixed to the snout by the aid of pliers made for the purpose. Although the pig is reputed to be a dirty animal, cleanliness is most essential in the sty, the court, the trough, and the food.

Points and Judging. The chief points of the pig are size, form and quality. Following these are the colour, and in the Berkshire, the marking of the head, ears, feet and tail, and the form of the face and snout. In judging pigs, form should be allied to size, which taken alone is not altogether an economical feature. Form assumes a minimum quantity of meat on the worst parts of the carcase and abundance on the best parts, such as the hams, sides, and loins. Form also embraces sufficient width of body where the heart and lungs are situated, for their development and play. In judging black pigs it is important to notice whether they have been artificially blacked to cover white spots or weakness in the depth of the colour of the skin.



LORD MORETON'S PIGGERY AT TORTWORTH COURT

Height from floor to ridge, 14 ft. 6 in. Width (interior), 27 ft.; including yards, 49 ft. 10 in.



GROUND PLAN

A. Central passage, 149½ ft. long by 5 ft. wide. B. Sties. C. Outer yards

It is also essential to determine, in judging young pigs, whether their age is correctly described, or whether they are represented as younger than they really are. British pigs practically suit all climates—except in the case of the Tamworth, which are almost restricted to one part of England—and are found everywhere. This is, in a measure, owing to the fact that pigs are almost essentially sty-fed stock largely depending upon purchased food, and, therefore, but little influenced by soil, rainfall, or temperature. The choice of variety chiefly depends upon the breeder's individual preference and the custom of the district in which he lives, this custom being governed in its turn by the preferences of the butcher and the dealer.

Weights. Young pigs may gain as much as 2 lb. in a day, but as age increases, during the fattening period the increase diminishes. The weight gained, too, depends largely upon the breed or cross-breed. Thus, the cross-bred pigs under nine months old which showed the highest gain at Smithfield in 1905 had made a gain of 1 lb. 10·8 oz., while the greatest gain made by a pair of pigs between nine and twelve months old was 1 lb. 5¼ oz. Compared with these figures the gains made by the Small Whites shown at the same time were very small, 13·1 oz. for the younger and 12¼ oz. for the older pigs. At the same exhibition the highest gain made by a single pure-bred pig was 1 lb. 10¼ oz., for a Large White just under twelve months, while the highest gain for a pair of pure-bred pigs was 1 lb. 9¼ oz., made by Large Blacks under nine months old. The following table, however, supplies details of the weights gained by pairs and single pigs of the leading breeds and cross-breeds respectively at the Smithfield exhibitions of the past three years.

AVERAGE WEIGHTS AND DAILY GAINS OF FAT PIGS AT SMITHFIELD

BREED AND AGE	Average Weight of Class in 1905.	Daily Gain from Birth. Average of 1903-4-5.	
	lb.	lb.	oz.
Small White—Two pigs under 9 months	206	0	12·83
,, Two pigs over 9 and under 12 months	243	0	12·18
Middle White—Two pigs under 9 months	287	1	2·68

Continued from page 2280

OUR KNOWLEDGE OF OURSELVES

Assimilation of Knowledge. The Folly of "Cramming." True Education. Awakening of Self-consciousness. Optimism and Pessimism

By Dr. C. W. SALEEBY

The Stupidity of "Cramming." The thoughtful reader will immediately understand why it is that cramming is such a useless method of study. The whole essence of cramming is to spend one's time, not in associating the items of one's knowledge, but in making them as numerous as possible per unit of time. The consequence is that the knowledge so obtained is retained only in proportion to the native retentiveness of the memory, which, in any case, is incapable of improvement, even by assiduous cramming for years. This cannot be too strongly insisted on—that though facts unquestionably come to be remembered by sheer repetition, there is no improvement of the memory in consequence; so far as the discipline and development of the memory are concerned, no mechanical methods are of any value. This, of course, is not the same thing as saying that they are of no value in so far as they help us to retain the subject to which they are applied; but it remains true that the only means of disciplining, developing, and strengthening the memory is to be found in association.

If this be true—and it is true—we are immediately supplied with a most important touchstone of educational systems. For instance, in learning how to conjugate a Greek verb, and, indeed, in all the learning of languages, which is arbitrary, the facts having no reasons that are given to the student, and there, therefore, being no associations formed—the mental discipline is nil.

Cramming is bad Discipline. Now, to be quite candid, it does not matter a straw what is said by the survivals from the old notions of education. They may assert until they are exhausted that their methods alone develop the mind, despite the unfortunate argument against them which their own minds display. In so far as this controversy is concerned, the psychology of memory is definite, precise, and demonstrative. The issue must not be confused. Those who recommend an imperfect knowledge of the apparently arbitrary grammar of the classics are entitled to say, if they please, that their practice involves a fine moral discipline; that it is a good thing to the boy who wants to be at the practice nets or on the ice to have to sit down and memorise the pluperfect of a Greek verb—a tense, by the way, which is never, or hardly ever, used by Greek authors. As to the moral discipline we are not here concerned. It is not our business to appraise the value of the moral discipline which consists in making a person do what he dislikes to do, on the simple ground that he does dislike to do it.

But in this course we are entitled to consider the alleged mental discipline of the so-called classical system—which was not practised and would have been execrated as idiotic in classical times. The psychology of memory teaches us, first of all, that there is no mental discipline whatever in cramming, and anyone will recognise at a glance that learning a declension is cramming. Furthermore, the old methods of learning by rote — that is to say, learning without reason, or without the association of ideas—inflict a positive injury, besides failing to accomplish that development of the mental powers which—and not the accumulation of undigested knowledge—is the end of education. The power of associating becomes atrophied by disuse, and the student comes more and more to rely either upon vain repetitions or upon the artificial devices which are usually known as mnemonics. These have an unquestionable practical value, comparable to that of large pockets in one's coat; but they have no more value in enabling one to use one's mental possessions well than a large pocket has in enabling one to use one's material possessions. To possess a very large number of items of information by such means is not to have a good memory in any sensible sense of the word.

The Best Memory. To have a good memory, in the proper sense of the word, is to have a good mind, to have a capable and vigorous thinking apparatus. It follows unquestionably that, in choosing subjects for the earlier scholastic education—the so-called primary and secondary education—it is necessary either to choose those which have utility in themselves, or those a knowledge of which depends upon, and in its turn tends to produce—accurate, ready, complicated, and yet controlled associations of ideas. The difference, in a word, is the difference between learning the first proposition of Euclid so that you are completely nonplussed when the letters are changed, or learning it so that you do not care what letters are used, and can write the whole thing out in algebraic form if necessary.

If our arguments are sound, it follows that there is little to be said for the choice of subjects which are without utility of their own and without any value in developing the memory. It is perfectly obvious that one might be able to recite everything written by Homer—or the "other man of the same name"—backwards, while standing on one's head, without having the faintest comprehension of what was meant, and without even the intelligence of a parrot. That is memory of a sort. Ultimately it is identical, in every essential particular, with the dent of your boot on the leg of your table. An impression was made on your table and it retains it, but on the whole it is worth rather less than nothing.

Self-consciousness. If the psychologist were asked to name the distinguishing characteristic of man's mind, he would answer that it is self-consciousness—the recognition of himself. We may recall Tennyson's lines: "The baby new to earth and sky . . . . hath never thought that this is I." Now we may be all agreed that the lower animals have never "thought that this is I." Even in their highest psychical developments, whether in the ant or the beaver or the domesticated dog, animals can never be credited with self-consciousness. It is scarcely less than amazing to notice how confused are many people when first they come to consider this question. The muddle between consciousness and self-consciousness in popular psychology is like the muddle between will and free-will. In the latter case, those who declare that the will is not free in the old-fashioned sense, are constantly asserted to be declaring that the will does not exist at all. Similarly, when self-consciousness, or the recognition of the self, is denied to the lower animals, people often think that we are denying their possession of consciousness.

Difference between Man and the Animals. What, then, is the *differentia* between consciousness and self-consciousness? It is surely expressed in the words of the poet who says that man is "A being of a large discourse, looking before and after." The self-conscious being is one who has come to identify himself as an independent thinking being, who can recall the past, saying to himself, "I was there," and who may anticipate the future, saying: "That will happen to me." There is no evidence whatever that this faculty of looking before and after is to be found in any of the lower animals. While we cannot too strongly insist in these days upon the continuity of man with his inferiors in the animal scale, and while we know that comparative psychology is the key to many of the problems of human psychology, we must nevertheless frankly recognise and point out any distinguishing mark of man, wherever it is to be found. This is necessary, indeed, for our own credit. However highly animals may be trained—by means of the intervention of man's mind—there remains an almost immeasurable gap between the highest intelligence displayed by any animal, even if it be a genius among chimpanzees, and the average mind of man. Our psychology will be apt to be laughed at if, in our analysis of various types of mind, we are unable to point to any processes, in the case of man, which serve to explain the gigantic gap that separates him from his nearest relatives.

The Child's Beginnings. Of course, it is necessary for us to trace self-consciousness to its beginnings as far as possible. If we seek to find its germ in the lower animals, we meet with very little success. It is exceedingly difficult to find anything but the barest rudiments of this faculty in them. So we must turn to the developing human being; and it is an exceedingly interesting inquiry to begin with the baby, which has "never thought that this is I," and to trace the gradual development of the conception of self through its various stages. It is quite impossible here to go into such a difficult question at due length. Merely would we insist upon the peculiar importance of the study, since it concerns itself with, and therefore serves in some degree to explain, the development of that conception or faculty which is the *only unique mark of man*, and which is the necessary condition of all those other powers and achievements which distinguish him.

Two points we may note in order to appetise the reader to feed himself. The first is that the child begins by identifying its own body as an independent entity. Its recognition of the fact that its hand belongs to itself, in a sense that its toy does not, is comparatively early. It is much later that the child identifies its foot as its own property in this complete sense. Gradually, however, beginning with the hand, the whole body is identified as in a special sense a personal possession. And it is from this recognition that the recognition of the self springs later.

Personality. The second point we may note is that the recognition of the self is long preceded by a recognition of the personal identity of the child, though the child does not identify that person with himself. The consequence is that he speaks of himself in the third person. Long before he has learnt the use of I, and can say "I want this," he says, "Baby wants this." He has now gone so far as to recognise himself as an independent entity, but he has not yet come to identify the identity recognised with the self that recognises it. But after a time he ceases to act as his own spokesman, and in some dim, half-unconscious way he comes to accept for himself the doctrine of which Descartes made so much—*Cogito, ergo sum*. I think, therefore I am.

It would lead us too far afield to inquire into the various disorders and peculiarities which self-consciousness may display. It is obvious that we have begun to raise the whole conception of personality, and this would lead us, if we followed it, to the amazing changes of personality which result from the action of drugs and disease, and also to the whole question of multiple personality where, to the old-fashioned thinker, it would appear that several souls had united in one body—now one, now another—proclaiming itself as the sole occupant.

If Memory were Abolished. Our business here, however, is more properly with the normal mind, and the point on which we must insist is this, that the question of memory can never be divorced from that of self-consciousness. It is not by accident that we have passed from the consideration of one to that of the other. One can know oneself as oneself only, in virtue of past experience. We are self-conscious creatures simply and exactly because we are able to live in the past and the future as well as the present. But abolish all memory—abolish not merely your recognised and available knowledge, but abolish all memory whatsoever—the firmly organised memory of your nervous tissues in virtue of which you tend to have certain habits, and all those memories which consist in modifications of your nervous tissue in consequence of past experience. What, then, will remain of your personality and your consciousness of self? These considerations are the key to the understanding of the mind diseased in many of its instances. We come to see how, in many curious changes of character, temperament, and personality, there has been tampering with the physical basis of memory, and that this is the key to the facts.

Self-consciousness and Internal Sensations. In considering the question of self-consciousness there is one practical matter which is of equal interest both to psychology and to medicine; and this is the part which the internal sensations play in self-consciousness. But we have insisted already in this course upon the importance of what may conveniently be called organic sensation. It is scarcely possible for us to conceive of ourselves at any moment except with some sort of conscious or unconscious appreciation of our state in terms of pleasure and pain. I say, for instance, "I am feeling very fit this morning," or "I am out of sorts," or "I am depressed," and so on and so on. The self is not only recognised as the self, but is recognised as having a particular state of well-being or ill-being, and ultimately all our acts are devoted—and this includes even our most unselfish acts—to the promotion of the well-being of the self. Now it is necessary here to insist that organic sensation plays a most extraordinary part in determining how far the self finds itself in a state of well-being or ill-being

We must further insist, in the strongest possible language, that the part played by organic sensation in this respect is out of all proportion to its intrinsic importance. Now this is not generally recognised except by the student who has seen mind on its abnormal side.

Optimism and Pessimism. Commonly, we assume that optimism and pessimism, the looking on the bright side of things or on their dark side, and, in general, the judgments of the optimistic philosophers like Leibnitz, or the later philosophers, Schopenhauer and Nietzsche, those appalling pessimists, are intellectual and rational conclusions of the unbiassed reasoning faculty. Now it may be a very materialistic comment, but it is nevertheless a mere platitude to those who are acquainted with the facts, that optimism and pessimism are very largely matters of digestion. That is the crudest way of putting it. In more general terms we may say that the whole vague and apparently negligible mass of sensations which reach us from the interior of our bodies influence the consciousness of self so as to make the self appear happy when one is in good health. But in the course of a very large number of disorders, ranging from the most trivial indigestion to the gravest and most permanent disease of the brain, these organic sensations may be modified with the most astonishing consequences. In one series of cases the self is raised to a state of preposterous exaltation. A dying pauper, his whole body riddled with disease, may be perfectly happy, and more than perfectly happy, imagining himself to be the Duke of Wellington or the Maker of all things, and writing cheques for millions where he has not a halfpenny. Such may be the influence of disordered organic sensation upon the self, or, if you please, upon the self's conception of itself.

In another series of cases, where every possible circumstance makes for happiness, where the patient may have a joyful and reassuring creed, friends, ease, and honour, his self is in a state of permanent misery. Familiar to all is the instance of poor Cowper. Organic sensation in such cases is disordered—whether in the terminals of the nerves in the organs or in the nerve-cells themselves in the brain, does not matter. The point is that in both classes of case the state of the self, biassed in one direction by what would appear to be an overwhelming number of external causes of the most potent kind, and biassed in the other direction by a mere vague group of organic sensations which cannot even be identified in consciousness, is irresistibly determined *by these last*, so that with every external cause for despondency and despair and even self-disgust, the self may be radiantly happy, while with every external cause for happiness, the self may yet be plunged in the very Inferno of despair.

The Mind is a "Whole." It is not possible to arrange psychology in such a simple fashion as one arranges chemistry, for instance, when considering one group of elements after another. For the mind, which is our object of study, is a *whole*. Nevertheless, we are proceeding on a definite plan. Proceeding from sensations and the immediate consequences of sensations in compelling the attention and in leading to action, we discussed the process by which the sensations of the past can be recalled in the present or, if not definitely recalled, can, at any rate, play their part. We went on to show that their principal part—and this applies to all memories, not merely those of simple sensations—is found in their providing the possibility of self-consciousness, and the making of a being who looks before and after. We then proceeded to show how the attitude of this being to existence is determined partly by his past experience, partly by his memories, but also, and in a most remarkable degree, by present sensations which do not form part of his experience in the ordinary sense, since they have nothing to do with the world around him—animate or inanimate—but depend upon his own internal constitution. Then we saw how the influence of these internal sensations may be directed so as to cause a man to be at the one extreme an optimist, and at the other a pessimist. This leads us to the extremely important matter of the psychological analysis of optimism and pessimism—a matter of great practical importance, and greatly neglected. When we have considered it as fully as space allows, we shall be prepared for a better understanding of one of the great subjects of psychology—namely, pleasure and pain.

MINING AND QUARRYING

The Importance and Development of Mining and Quarrying. Mineral Deposits: Their Location and Characteristics. Tools for Prospectors

By D. A. LOUIS

MINING and quarrying are those industries which have for their object the extraction of useful minerals from the crust of the earth. It is particularly significant that by means of capital and labour they create wealth by rendering useful and marketable materials which are unproductive and unremunerative as long as they remain undisturbed in the earth. They are of extreme antiquity, and are alluded to directly or indirectly in the Bible and other ancient records. In fact, their influence on civilisation has been remarkable, and there is very little doubt that the progress of the human race has always advanced hand in hand with the better utilisation of the products of the mineral kingdom, or, in other words, with the fruits of mining and quarrying. This is true from the most ancient times to the present day. Archeologists even classify the past periods of human existence as the Stone Age, the Newer Stone Age, the Bronze Age, and so on, gauging the advancement of humanity by the better use it made of mineral products.

Why are Mining and Quarrying Important? The reason for their importance is not far to seek, for do not mining and quarrying provide the sinews of warfare in the form of coin, and the bone and muscle as well in the form of fortifications and warships, guns and ammunition, all mainly of mineral origin, leaving, so to speak, the nerves, brain, and flesh of warfare to the animal and vegetable kingdom? Fighting is here placed first because we are always fighting something or somebody. Moreover, a good fighter can mine and quarry or do anything else in peace.

1. VEIN FORMATION

The position of these industries in peaceful occupations is, however, equally well attested, for they provide material for our buildings, for our means of communication—roads, railroads, or ships—for our fuel, for our machinery, and what not. In fact, one of the few things we do not do with minerals is to devour them in bulk, although we consume them plentifully in the form of mineral waters, medicines, and with and in our food.

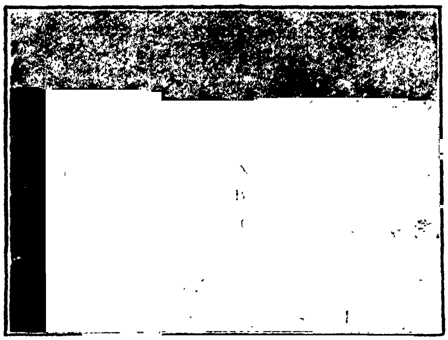
The object of mining and quarrying is, and always has been, to supply the world with its mineral requirements. In achieving that, they give, and have given, employment to vast numbers of people and to immense amounts of money, both, when expressed numerically, going into many many millions, and both always on the increase. In our own country, in 1904, there were 877,057 people employed in mines and 97,577 in quarries, and minerals of the value of £97,477,639 were produced. The mere existence of mineral wealth in a district is not sufficient; it must be mined or quarried to be turned to account. Moreover, the demands for mineral products is so great that deposits are constantly being sought in all parts of the world, and wherever and whenever possible, are worked as a result.

What Mining and Quarrying Produce. The significance of mining and quarrying will perhaps even be better appreciated when some of the varied products are mentioned. They include the ores from which are obtained the well-known metals: gold, silver, copper, iron, lead, zinc, tin, quicksilver, and the lesser-known metals, manganese, nickel, cobalt, aluminium, arsenic, antimony, bismuth, chromium, platinum, tungsten, vanadium, uranium (radium), etc. They include also precious stones, ornamental stones, building stones, millstones, grindstones, oilstones, whetstones, slates, and such like; the fuels and allied minerals: coal, peat, ozokerite, petroleum, natural gas, oil-shale, jet, graphite, bitumen, asphalt, amber, etc.; clays of different kinds for pottery, for earthenware, for brick-making, etc.; gravel, chalk, cement, gypsum, bauxite, felspar, flint, fluorspar, fullers' earth, lime, marl, pumice, ganister, sand, etc; attritive material, such as emery, quartz, garnet; chemical substances, such as alum, bromine, iodine, barytes, borax, potash, soda, potassium salts, pyrites, saltpetres, strontium, sulphur, monazite, common salt, etc.; pigments, mineral waters, carbonic acid, phosphates, and such sundries as asbestos, infusorial earth, mica, talc, and rare earths.

The useful minerals we produce in our own country include the following: alum shale, arsenical pyrites, barytes, bauxite, chert and flint, clay and shale, coal, copper ore, copper precipitate, fluorspar, gold ore, gravel and sand, gypsum, igneous rocks, iron ore, iron pyrites, lead ore, limestone, manganese ore, mica, natural gas, ochre, umber, oil-shale, phosphate of lime, salt, sandstone, silver ore, sulphate of strontia, tin ore, uranium ore, wolfram and zinc ore. It will be seen that civilisation would indeed be quite impossible without many of the products of mining and quarrying.

Information about these products has already been furnished and is accessible to the reader in the courses on Building. Materials and Structures, Geology, Chemistry, etc., so do not call for repetition here.

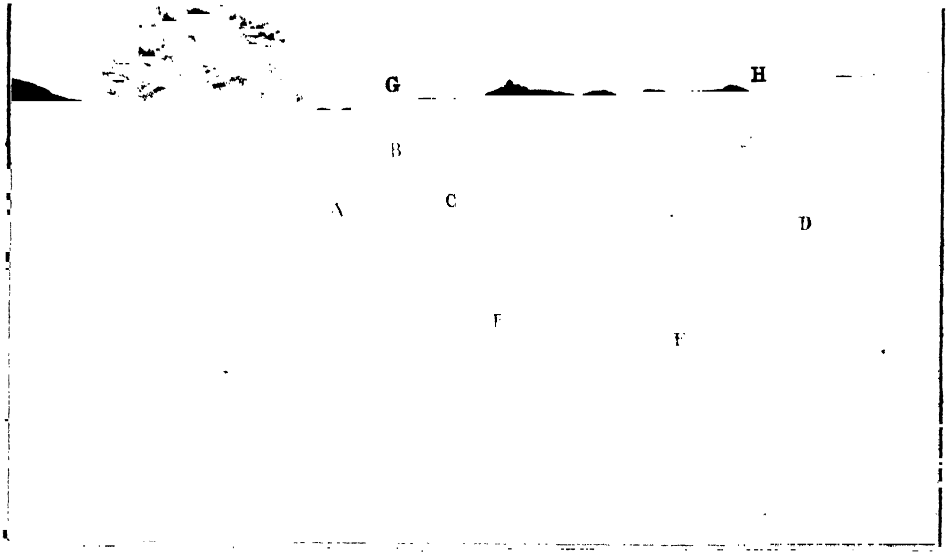
Extent of the Mining Field. The entire world is the field of mining operations; in fact, to the workers in these industries we owe the discovery of many new places, the development of many countries, the foundation of townships, and the establishment of whole communities. This was true in the days gone by, and is true now. Many towns in Western America owe their existence and wealth entirely to mining enterprises; the same is true of Australia, of New Zealand, and South and West Africa. In fact, had the few square miles of territory in the Transvaal been merely agricultural country, and not gold bearing, there would have been no vast accumulation of peoples of different nations, no South African War, and no Chinese labour question for the 1906 electorate. Mining, too, is not restricted to any particular zone; the torrid zone, the two temperate zones, and even the Arctic zone are invaded by the intrepid workers in these industries. In fact, many populous regions in the world would be supporting a very scanty population, or even none at all, were it not for mining and quarrying operations.



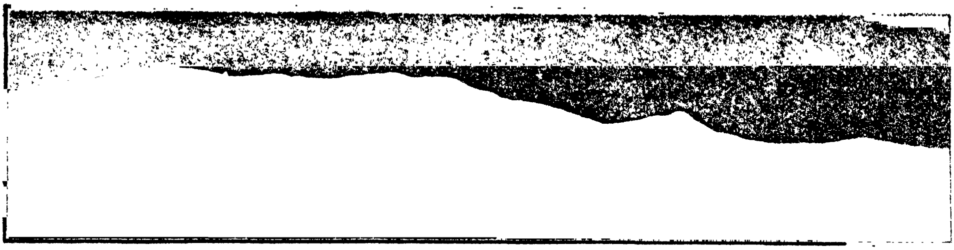
2. WORKINGS IN MIOCENE LIGNITE AT BOVEY TRACY, DEVONSHIRE
(Geologist Association, London)

The man who adopts mining for a livelihood should have no aversion from adventure and travel, for it would be difficult indeed to find a country where mining or quarrying operations of some sort are not in progress. In connection with these industries it may well be said that the world is their field.

The Scene of Activity. The crust of the earth is the region of the miners' and quarrymen's activity where they do their delving and digging; but, again, the courses on Geography and Geology have dealt so fully with this subject that here it is necessary

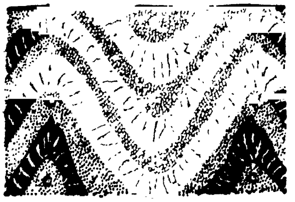


3. PIT IN LIAS BEDS, RUGBY CEMENT WORKS, SHOWING FOLDED STRATA
(The Geological Survey)



4. OUTCROP OF IRON ORE, KIIRUNAVAARA, LAPLAND

only to make a passing reference to this part of our subject. In the course on Geography it has been demonstrated that the solid outside or crust of the earth, although only a very insignificant proportion of the whole mass of the earth, is very diversified in configuration, here rising into mountains, there sinking into immense basins and valleys, some filled by the ocean, some by inland seas and lakes. The study of geology has shown that this crust is made up of different kinds of rocks, some of which consist of material that has cooled down from a molten state and are called *igneous* rocks, others consisting of material that has been deposited from water in layers, and are called *sedimentary*, *stratified*, or *aqueous* rocks, while others again, consisting of igneous or sedimentary rocks altered in the mass, are called *metamorphic* rocks. These rocks, it has been shown, have been subjected to various powerful agencies throughout immense periods of time, and have not only been worn away, dislocated, shifted, and tumbled about, but have become jointed, cracked, fissured, crushed, crumpled, folded, and what not. These disturbing influences have, in fact, given rise to the various irregularities of the crust of the earth, including the mountains, valleys, ravines, plains, and faults. Many examples of this will be encountered in subsequent figures, but 3 furnishes a very good example of folding, with the anticline at A B C, and the synclinal basin at D. The men at E and F furnish a scale for the size of the banks, while the surface at G H shows how denuding agencies have worn down these beds to an almost dead level at the surface.

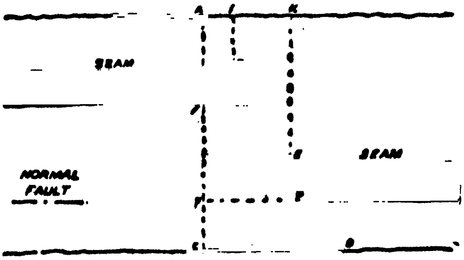


5. BENDIGO SADDLE REEF
(B. H. Brough)

Location of Mineral Deposits. Where are useful minerals found in the crust of the earth may well be the next question. They are in some cases found constituting the entire mass of stratified, igneous, and metamorphic rocks, but they form in other instances mere deposits in such rocks. They are found throughout the whole series of geological ages from the Archæan to the most recent, although certain valuable mineral deposits do affect certain areas and certain associations. Finally, they may be found in the mountain, in the valley, in the plain, and even below water. And the deposits are called according to their character and position—*alluvial* deposits, *beds* or *seams*, *veins* or *masses*.

Alluvial Deposits. Alluvial deposits are those found filling up the bottoms of ancient or modern river valleys, and consist of the waste material which has been carried down by rivers and deposited wherever or whenever the current became sluggish. They consist of irregular layers of gravel, sand, clay, interspersed with organic detritus, pebbles, and even boulders. Sometimes only one of these materials prevails, sometimes two or more of them. The gravel pits in the Thames Valley, the tin deposits of the Red River in Cornwall, the gold placers of California, New Zealand, and Western Siberia are examples of such deposits, of which a vast number occur in different parts of the world.

Beds or Seams. A bed or seam is simply a special member of a group of stratified rocks; it therefore partakes of the characters of stratified rocks [see GEOLOGY], may be horizontal, inclined, folded, or faulted. It may extend in length and breadth for thousands of yards, or may be confined to a restricted area. It may be uniformly a few inches or many feet thick, or it may vary considerably in thickness, dwindling away gradually in one part, while increasing in size in another. A bed may even be split into two or more seams by the interstratification of some *parting* or worthless rock. Seams are also occasionally interrupted and altered by the intrusion of igneous rocks; the whin-sill in Northumberland is an example of this kind of disturbance. At other times gaps occur in seams, representing the bed of an ancient river; these are known as *wash-outs* or *dumb-faults*. But, in spite of these irregularities, a bed is much more uniform in thickness and composition than a vein. As in the case of other stratified rocks, the direction of its length is called the *strike*, and the direction of its breadth or inclination the *dip*. The bed immediately above is known as the *roof*, and the one below it as the *floor*. In the photograph of a stratified deposit [2] the strike of the beds is across the figure, and the dip is away from the spectator, and in reference to the seam of light material B, A is the roof, and C is the floor. In 3 it will be seen that the same beds may dip in opposite directions as at the positions A and C. One of the most useful characters of seams and beds from a mining and quarrying point of view is the system of *joints* in three different planes so common in stratified rocks. The great coalfields of America that stretch for thousands of square feet nearly horizontally, the restricted coalfield of the Forest of Dean, the faulted coalfields of Belgium, and the nearly vertical coal seams of the St. Etienne district in France, are all, as well as all other coalfields, examples of bed or seam deposits. So, too, are all limestone, sandstone, chalk, slate, and such deposits; as well as the smaller bands of iron ore, of brick earth, and of some other materials included in the list of useful mineral deposits.

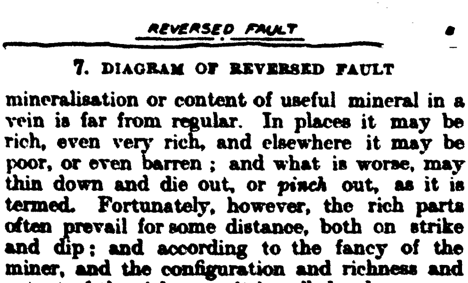


6. DIAGRAM OF NORMAL FAULT

Veins, or Lodes. Veins, or lodes, are deposits that take a tabular or sheetlike form, and extend with more or less verticality into the ground, the material in them being different to that of the surrounding rock [1B]. They may extend into the ground to a great depth or be quite shallow; they may stretch across country for miles, either availing themselves, or not, of any natural divisions of the rocks in which they occur. They may occur in any kind of ground, but are more frequently encountered in the older stratified rocks, in metamorphic and in igneous districts, than in the newer stratified formations. They may vary in width or thickness from a few inches to many feet even in the same deposit. The contents mostly form a more or less confused mass, although there is always a certain amount of regularity of distribution; but frequently they form two or three or even several more or less continuous sheets of distinct minerals, such, for instance, as quartz, fluorspar, calcite, blende, galena, pyrites, and suchlike, which run parallel with the length and breadth of the vein, and consequently give such veins in cross-section a banded structure or appearance. In a district where veins occur there are generally several veins running more or less parallel, and others, again, running in a different direction; the latter are known simply as *faults* or *cross courses* if they are not mineralised—that is, if they contain only worthless minerals. If, however, they are mineralised, they are called *counter veins*.

Different Forms of Veins. However, it must always be remembered that all veins are fissures or cracks that have become filled up. Veins that penetrate deeply into the ground and take a strong course across country are called *fissure veins*. When, on the contrary, the vein goes only a little way into the ground and does not extend far or strongly across country, it is known as a *gash vein*; when the rocks on each side of the veins are different, the vein is known as a *contact vein*, and when the vein is not mineralised it is known as a *barren vein*. The rock through which the vein runs is known as the *country*, or frequently as the *country rock*. The direction that the vein takes across country is known as the *strike*, and the direction that it takes into the ground the *dip* when compared with the horizontal, but the *hade* or *underlie* when the inclination is compared with the vertical. Both the strike and dip may vary in direction within a few feet, so that although in the long run they have a general direction, the course is often irregularly serpentine in case of the strike, and somewhat choppily wavy in the case of the dip. The containing sides are known as the *walls*, the upper one as the *hanging wall* [1A], the under one as the *foot wall* [1C], and owing to vagaries of dip occasionally the foot wall may for some distance be really a hanging wall, or the reverse may be the case, but to avoid confusion the original names should be adhered to. The thickness of a vein is measured on a line ttaken at right angles to the walls across the vein.

Vein Formation. Veins are not filled solely with useful minerals or ore, for more frequently than otherwise the accompanying minerals known as *vein-rock*, *vein-stuff*, *matrix* and *gangue* are worthless, and constitute the preponderating part of the filling. Frequently, too, a layer of clay, known as *selvage* or *gouge*, lines the inside of the walls of veins, while another intruder in veins occasionally encountered, and known as a *horse*, consists of a piece of the country that has fallen in during the period of filling, and has become included in the contents; this may be quite small and inconsiderable, or very large, and measure many feet high, many feet thick, and many feet long. It is noteworthy that the mineralisation or content of useful mineral in a vein is far from regular. In places it may be rich, even very rich, and elsewhere it may be poor, or even barren; and what is worse, may thin down and die out, or *pinch* out, as it is termed. Fortunately, however, the rich parts often prevail for some distance, both on strike and dip; and according to the fancy of the miner, and the configuration and richness and extent of the rich area, it is called a *bonanza*, a *shoot*, a *pocket*, a *bunch*, a *pipe*, a *chimney*, a *course of ore*, and even other fanciful names.

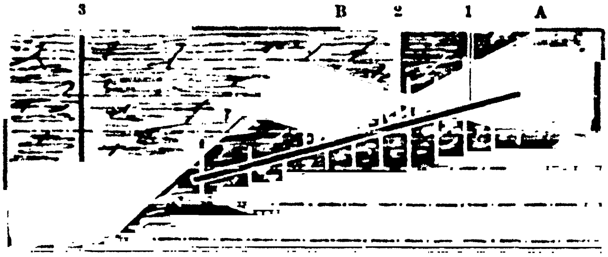


7. DIAGRAM OF REVERSED FAULT

Another feature associated with veins is the occurrence of smaller veins, which appear sometimes to run into, and sometimes to branch from, the main veins and are known as *leaders, branches, feeders, droppers, strings*. In some cases, again, useful mineral is contained in a network of small veins which intersect the country or the vein-rock at all angles, forming what are known as *stockworks*, which about form the border line between masses and veins.

To obtain a good idea of a vein, two sheets of slightly crumpled paper should be held steeply inclined and parallel to one another, so as to leave a space between them ; then imagine this space filled with vein-rock, etc., and the space beyond the pieces of paper to be the country. The upper sheet of paper would represent the hanging wall, the lower one the foot wall, the inclination the dip or hade, and so on. The crumplings would serve to demonstrate the local variations in thickness, dip, and strike.

Masses. Masses of useful minerals may consist of great bosses of metamorphosed or igneous rock, such as many of the deposits of basalt, granite, syenite, etc., so extensively quarried for building purposes and road making, and masses of marble ; or they may consist of small or large accumulations of useful mineral filling joints and cavities in rock, such as the iron ore deposits of Cumberland. Or, again, they may consist of stratified or unstratified rocks, simply mixed with or impregnated with useful mineral. The copper bearing slates of Mansfeld, in Germany, and the lead ore deposits of Mechernich, in Prussian Rheinland, are examples of such masses in stratified rocks ; while the tin capels in Cornwall are examples of them in unstratified rock. The famous saddle reefs of Bendigo, Victoria, may be regarded as forming the border line between masses and bedded deposits. These are illustrated in 5. They occupy fissures that, owing to the bedding of the strata, have assumed a shape that in cross-section has the appearance of a saddle. The enclosed rocks B and C are contorted slates and sandstones of Lower Silurian age. The reefs are shown at A and D. In fact, in the distribution of the useful material, and in general character, masses are, like beds and seams, more regular than veins, but their magnitude is uncertain.



8. FAULTED SEAM IN A BOHEMIAN COALMINE

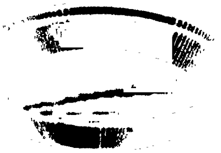
Outcrop. The *outcrop* is that part of any deposit which reaches the surface, whether it be on a hill, in a valley, or cliff face. The outcrop shown [4] is a striking feature in the otherwise flat country, and forms the crowning ridge of a range of hills about three miles long.

Deposits Vary with Character of the Country. The character of the country occasionally exerts a marked influence on the character of the contents of a vein or mass, and in some cases a change in country is accompanied by a change in the structure of a vein. In the Alston Moor district in Cumberland, for instance, the veins of lead ore pass through beds of limestone, sandstone, and shale, and are usually more productive in the limestone than in the sandstone or shale. In Derbyshire, the lead deposits are productive in the limestone, but rarely yield ore in the inter-bedded igneous rock, locally known as *toadstone*. In Cornwall, the veins in the clay-slate, or killas, bear chiefly copper, while the same veins in granite below carry tin. At Wortherton mine, in Shropshire, the deposits of barytes can be worked where the adjacent rock is volcanic ash, but are valueless in the shale country of the district. The *kindness* or otherwise of the country, moreover, is a very important factor in the working.

Faults in Seams. Of all the troubles that useful mineral deposits suffer, faults are the most common and most aggravating. Faults affect the useful deposits in exactly the same way as they affect other deposits dealt with in the Geological course, and therefore we need consider them solely from a mining point of view. Only the simplest cases, which also are those most frequently encountered, can be considered here; *step faults* and *trough faults*, etc., are of rarer occurrence. A bed or seam is said to be *thrown* when displaced by a fault, while a vein is *heaved*, the displacement being more or less vertical in the former, and lateral in the latter case. When a fault is encountered in working a seam, it is recognised by the sudden termination at a wall of other rock ; the point of contact first observed should be carefully noted, and if the interruption be first detected in the roof, and slant away towards the floor, the throw is most likely a *down-throw*, and the continuation of the seam on the other side of the fault would be found by cutting through the fault and conducting exploratory operations downwards. The contrary condition of things would indicate an *up-throw;* then the exploratory operations would be directed upwards. Boring comes in useful for this purpose. If the seam is not found within a reasonable distance, a reversed fault may be the cause of the trouble, and the exploratory operations would be conducted to test this point.

In the diagrams 6 and 7 the properties of faults are set forth ; AB is the fault in each case. In 6 the angle CAB is the hade of the fault, FH is the throw or vertical displacement, IK is the width of the fault or horizontal displacement or shift ; in this area a shaft sunk would meet with no coal; it is known as the *want*. Approached from the left this fault would be a down-throw; approached from the right it would be an up-throw. DE is the slip or the displacement on the incline. In the reversed, overthrust or overlap fault [7] the angle CDE or IED is the hade of the fault AB, FG or DC the vertical displacement, DE the overthrust; HI is the horizontal displacement, and a shaft sunk within this area would encounter the seam twice; it is hence known as the *repeat*.

In 8 is shown an actual occurrence encountered in a coalmine in Bohemia. The fault was first observed in working the seam on the right, where the end of a level is shown. Boreholes Nos. 1, 2, and 3 were successively put down, and the hade of one of the faults, A (for there are two of them—step faults, in fact) as well as *the position of the continuation of the seam, determined. Then the inclined drivage indicated was made, starting from the level on the right,* boreholes being put out at intervals, as shown, to investigate matters further. These boreholes disclosed the position of the intermediate portion of the seam, and, by means of the last upward borehole from the inclined drivage, the existence of the second fault, B. From left to right the faults are up-throws; from right to left down-throws. The throw of the first is 15 ft., of the second over 100 ft.; the slip 60 ft. and 140 ft. respectively, and the shift a few feet and 50 ft. The incline as shown is 285 ft. long.



9. PAN FOR GOLD WASHING

Faults in Veins. In the case of a vein the angle that the vein makes with the fault or cross-course should always be carefully observed and in most cases the continuation of the vein will be found on the side of the greater angle. In 6 the angles the seam makes with the fault at L and E are greater than those at D and G. Various investigators have studied the question of faults, and one of these, Zimmerman, has laid down the following rule for finding the vein on the other side of a fault. The line of strike of the fault is set down upon paper, and the horizontal projection of the line of intersection is ascertained by construction, and from the point where the fault is met by the lode a line at right angles to the fault is drawn towards its opposite wall. Then, after cutting through the fault, the continuation of the lode is to be sought on that side of the line of intersection that this perpendicular falls.

Points about Faults. The heave of a vein is called right-hand or left-hand, according to the position of the heaved portion of the vein. It will be observed that the term up-throw, down-throw, right-hand heave, left-hand heave, are simply relative terms, for a right-hand heave approached from the other side becomes a left-hand heave, and a down-throw in the same way becomes an up-throw. Pieces of cardboard fitted together at different angles and inclinations may advantageously be used to study the effects of faults on veins. Having now learnt something about the character and peculiarities of valuable mineral deposits, the methods used to discover them may next be considered.

Prospector's Equipment. The equipment for purposes of discovery is a matter for serious consideration, as it is extremely important not to be over-burdened with impedimenta. The outfit, however, should include a pick, a small chisel or gad, a hammer [10]—the pick and hammer can be combined in one implement—a spade, a shallow circular iron dish with sloping sides called a pan [9], a pocket lens, a pocket-knife, a magnet, a clinometer, a compass—or better still, a clinometer and vertical angle scale combined with a prismatic compass—a tape or steel band measure, and a foot-rule; *while small bags for holding specimens, and pockets, or a larger bag in which to carry them, are indispensable. It is well to have a blowpipe set with reagents, and a set of minerals for testing hardness,* accessible in the camp if not in the field; and in many instances a balance and weights are useful. Of course pencils, pens, and notebooks are essential; if the latter are of squared paper they are particularly useful for sketching to scale.

10. PROSPECTOR'S HAMMER (Hardy Pick Co.)

Use of the Appliances. The pick serves for breaking ground, the hammer for smashing and crushing lumps, the chisel or gad for working out fossils or minerals, the spade for handling the broken material, the pan for washing crushed material, sand, or loose dirt, etc. For the last-mentioned purpose the dirt is put into the pan and mingled with water, a swinging and circular motion is given to the pan so as to cause the whole sloppy magma to swirl round, and by repeatedly washing away the lighter matter off the edge, only the heavier matter containing the valuable material remains, and can be estimated and examined with the pocket lens and magnet, and if reagents and blowpipes are available may be further tested. The pocket lens and hardness set serve for examining lumps of rock for useful minerals, and isolated minerals themselves. The compass and other instruments serve for finding the way and observing the direction of strikes, dips, etc., while hade or dip can be measured by the clinometer. A very considerable amount of information can be obtained by the adroit use of these few simple appliances.

ALGEBRAIC EQUATIONS

Simple Equations. Definitions. Simultaneous Simple Equations of the First Degree containing Two and Three Unknown Quantities

continued from page [illegible]

By HERBERT J. ALLPORT, M.A.

SIMPLE EQUATIONS

43. An *equation* states that two algebraical expressions are equal. The two expressions are called *sides* of the equation.

If, however, the two expressions are equal for *all values* of the letters involved, the equation is generally called an *identity*. The name *equation* is applied to the cases in which the expressions are only equal for some particular values of the letters involved.

For example,

$$(x + a)(x + b) = x^2 + (a + b)x + ab$$

is an identity, since these two expressions are always equal whatever the values of x, a, and b may be.

$$3x + 7 = 2x + 9$$

is an equation, since the two expressions $3x + 7$ and $2x + 9$ are only equal in the particular case where $x = 2$.

44. In the latter example, x is called the *unknown quantity*. The process of finding the value, or values, of the unknown quantity for which the equation is true is called *solving* the equation. These values are called the *roots* of the equation, and are said to *satisfy* the equation.

It is usual to express unknown quantities, whose values have to be found, by letters from the *end* of the alphabet, x, y, z. Quantities whose values are supposed to be known are represented by letters from the *beginning* of the alphabet, a, b, c.

45. If equations contain only the *first* power of the unknown quantities they are called *simple* equations, or equations *of the first degree*.

We shall first consider equations which contain only one unknown quantity.

Suppose we have to solve the equation

$$4x - 3 = 2x + 7. \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Since these two expressions, $4x - 3$ and $2x + 7$, are equal, the results obtained by subtracting $2x$ from each of them will be equal.

Therefore

$$4x - 3 - 2x = 2x + 7 - 2x;$$

or,

$$4x - 3 - 2x = 7.$$

Again, if we now add 3 to each side of the equation, the two sides will still be equal.

Hence,

$$4x - 3 - 2x + 3 = 7 + 3;$$

or,

$$4x - 2x = 7 + 3. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Compare the result (2) with the original equation (1). Each contains the same terms, but in (2) the terms which contain x are on one side of the equation, and the numerical terms are on the other. Also, we see that the term $2x$ in (1) is on the right, and is +, while in (2) it is on the left and is −. Similarly, −3 on the left of (1) becomes +3 on the right of (2). That is, *we may move a term from one side of an equation to the other, provided we change its sign.* A term which is moved from one side to the other is said to be *transposed.*

If we now collect the terms on each side of (2) we get

$$2x = 10;$$

and it is clear that if we divide equal quantities by the same quantity, the quotients will be equal. Hence, we now divide both sides of the equation by 2, and obtain the result $x = 5$.

46. *The essential part of the process, then, is to put all terms which contain the unknown quantity on to one side of the equation, and all other terms on to the other side, remembering that when we transpose a term we must change its sign.* We then collect the terms on each side of the equation, and, finally, divide both sides by the coefficient of the unknown quantity.

Very often, however, the equation requires some simplification before we are able to transpose the terms, as will be seen from the following examples:

Example 1. Solve $4(x - 3) - x = 2(x - 1)$.

Here we must first remove the brackets.

Thus,

$$4x - 12 - x = 2x - 2.$$

Transposing,

$$4x - x - 2x = -2 + 12.$$

Collecting terms,

$$x = \underline{10} \ \textit{Ans.}$$

The student can always *verify* his results—*i.e.*, test whether the value found does satisfy the equation—by substituting the value in both sides of the equation.

Thus, in Example 1, if we put $x = 10$ in the left side of the equation, we obtain

$$4(10 - 3) - 10, \text{ which equals } 18.$$

Again, putting $x = 10$ in the right side of the equation we get $20 - 2$, or 18. Since the two results agree, we know that the solution is correct.

Example 2. Solve

$$\frac{x + 1}{2} + \frac{2x - 3}{3} = 5 - \frac{3x - 1}{4}.$$

It is evident that if the sides of the equation are equal, the products obtained by multiplying both sides by the same quantity will be equal. We multiply all through by 12, the L.C.M. of the denominators 2, 3, 4, and thus get rid of the fractions.

For $\frac{12(x+1)}{2}$ equals $6(x+1)$,

$\frac{12(2x-3)}{3}$ equals $4(2x-3)$,

and so on.

Hence, the working of our equation is written out as follows,

Clearing fractions,

$$6(x+1)+4(2x-3)=60-3(3x-1),$$

or,

$$6x+6+8x-12=60-9x+3.$$

Transposing,

$$6x+8x+9x=60+3+12-6.$$

Collecting terms,

$$23x=69.$$

Dividing by 23,

$$x=\underline{3\ \textit{Ans.}}$$

With a little practice, the fractions are cleared and the brackets removed in the same process. The chief point to remember is that *if a fraction has the sign − before it, the signs of the numerator must be changed when we clear the fractions.* For instance, in the above $5-\frac{3x-1}{4}$ became $60-9x+3$, *not* $60-9x-3$.

Example 3. Solve

$$a(x+b)+b(x-a)=a^2-b^2.$$

Removing brackets,

$$ax+ab+bx-ab=a^2-b^2.$$

Collecting terms,

$$(a+b)x=a^2-b^2.$$

Divide by $(a+b)$, the coefficient of x; then

$$x=\underline{a-b\ \textit{Ans.}}$$

Example 4. Solve

$$(x+1)(x+3)+(x+2)(x+4)=2(x+3)^2.$$

Removing brackets, Art. 31,

$$x^2+4x+3+x^2+6x+8=2x^2+12x+18.$$

Transposing,

$$x^2+4x+x^2+6x-2x^2-12x=18-3-8.$$

Collecting terms,

$$-2x=7.$$

Dividing by −2,

$$x=\underline{-3\tfrac{1}{2}\ \textit{Ans.}}$$

EXAMPLES 7

Solve the following equations:

1. $5(2x-1)-3(x+4)=3(x-3)$.
2. $3(1-x)-2(3+5x)+x=0$.
3. $\frac{x}{2}-\frac{x}{3}=2$.
4. $\frac{1}{2}(x-2)-\frac{1}{3}(x+4)=\frac{1}{4}(5x-2)$.
5. $3(x+1)^2+4(x-3)^2=7(x-1)^2$.
6. $\frac{x+\frac{1}{2}}{2}-\frac{3x-\frac{1}{2}}{4}=\frac{x-\frac{1}{3}}{3}$.
7. $5x-\{6-2(2x-3)-x\}=2(1-2x)$.
8. $(x+a)^2-(x+b)^2=(a-b)^2$.
9. $\frac{a}{x}+\frac{b}{x}=c(a+b)$.
10. $(x+a)^3+(x+b)^3+(x+c)^3=3(x+a)(x+b)(x+c)$.

SIMULTANEOUS SIMPLE EQUATIONS

47. So far, our equations have only contained *one* unknown quantity. If an equation contains *two* unknown quantities, we can find as many pairs of values of the unknown quantities as we please which will satisfy the equation.

For, consider the equation

$$2x-3y=2.$$

From this we see that $2x=3y+2$, and therefore $x=\frac{1}{2}(3y+2)$. Hence, if we give y any value we please, we obtain a corresponding value for x.

Similarly, if we have a second equation, containing the same unknown quantities x and y, such as

$$x+3y=10,$$

we know that $x=10-3y$, and we are again able to find as many pairs of values of x and y as we please which will satisfy the equation.

But, if both equations are to be satisfied by the *same values of x and y*, then the two expressions $\frac{1}{2}(3y+2)$ and $10-3y$ must evidently be equal.

Thus

$$\tfrac{1}{2}(3y+2)=10-3y,$$

and, if we solve this equation by the methods of Art. 46, we find that $y=2$. Therefore, since we know that $x=10-3y$, we have $x=10-6=4$.

Hence we see that if the equations

$$\begin{aligned}2x-3y&=2\\x+3y&=10\end{aligned}$$

are to be satisfied by the *same* values of x and y, the only solution possible is $x=4$, $y=2$.

48. Two or more equations which are to be satisfied by the same values of the unknown quantities are called *simultaneous equations.*

The *degree of an equation* containing two unknowns, x and y, is the degree of that term which is of the highest dimensions in x and y. [Art. 29.]

Thus,

$2x-3y=2$, is of the *first* degree.

$3xy+4=10x$, is of the *second* degree.

Similarly, if there are three unknowns, x, y, and z, the term of highest dimensions in x, y, and z determines the degree of the equation; so that $x+2y+3z=0$ is of the first degree, and $ax^2+byz=cx$ is of the second degree.

49. *For the present we shall only consider equations which are of the first degree.* We shall see that to find the values of *two* unknowns we require *two* equations, to find *three* unknowns we require *three* equations, and so on.

Example 1. Solve the equations,

$$4x-3y=18 \quad . \quad . \quad . \quad . \quad (1)$$

$$3x+2y=5 \quad . \quad . \quad . \quad . \quad (2)$$

For the sake of reference it is convenient to number our equations.

Our object must be to form an equation, by the aid of (1) and (2), in which either the x or the y is wanting. The process by which we do this is called *elimination*, and the unknown quantity thus got rid of is said to be *eliminated.*

Suppose we eliminate y. In (1) the coefficient of y is 3, in (2) it is 2. The L.C.M. of these coefficients is 6. We can, therefore, by multiplication, make 6 the coefficient of y in each equation. Hence, multiply (1) by 2, and (2) by 3, and we get

$$8x - 6y = 36. \quad . \quad . \quad . \quad . \quad (3)$$
$$9x + 6y = 15. \quad . \quad . \quad . \quad . \quad (4)$$

It is clear that if we now add the corresponding sides of the equations (3) and (4) we shall eliminate y.

Thus,

$$17x = 51.$$

Therefore, dividing by 17, we have

$$x = 3.$$

We can eliminate x in a similar way from the equations (1) and (2) and so obtain the value of y. Or, knowing the value of x, we can substitute this value for x in either (1) or (2), which is often a simpler elimination than the other.

Substituting the value of x in (1), we have

$$12 - 3y = 18.$$

Therefore,

$$3y = 12 - 18$$
$$= -6$$

so that,

$$y = -2.$$

Thus, the required solution is $x = 3$, $y = -2$.

Example 2. Solve the equations

$$\tfrac{1}{3}(x - 1) = \tfrac{1}{4}(y + 1). \quad . \quad . \quad . \quad (1)$$
$$\frac{2x - 3}{5} + \frac{2y - 13}{7} = 0. \quad . \quad . \quad . \quad (2)$$

We must first clear the fractions, as in Ex. 2, Art. 46, and transpose the terms. Thus,

Multiply (1) by 12,

$$4x - 4 = 3y + 3.$$

Therefore,

$$4x - 3y = 7. \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Multiply (2) by 35,

$$14x - 21 + 10y - 65 = 0.$$

Therefore,

$$14x + 10y = 86. \quad . \quad . \quad . \quad . \quad (4)$$

We now solve the equations (3) and (4) just as we did Ex. 1 above. Multiply (3) by 10 and (4) by 3, and add.

Then,

$$40x + 42x = 70 + 258;$$

or,

$$82x = 328.$$

Therefore,

$$x = 4.$$

Substitute this value in (3).

Then,

$$16 - 3y = 7,$$
$$-3y = -9.$$

Therefore,

$$y = 3.$$

We thus have

$$\left.\begin{aligned} x &= 4 \\ y &= 3 \end{aligned}\right\} \underline{Ans.}$$

Example 3. Solve

$$(b + c)x + (b - c)y = 2ab. \quad . \quad . \quad . \quad (1)$$
$$(c + a)x + (c - a)y = 2ac. \quad . \quad . \quad . \quad (2)$$

We eliminate y in exactly the same manner as before.

If we multiply (1) by $(c - a)$ and (2) by $(b - c)$ the coefficient of y will become $(b - c)(c - a)$ in each case.

Hence, multiply (1) by $(c - a)$ and (2) by $(b - c)$ and subtract.

Then,

$$\{(b + c)(c - a) - (c + a)(b - c)\}x = 2ab(c - a) - 2ac(b - c).$$

Therefore,

$$\{bc - ab + c^2 - ac - bc - ab + c^2 + ac\}x = 2abc - 2a^2b - 2abc + 2ac^2.$$

Collecting terms,

$$2(c^2 - ab)x = 2a(c^2 - ab).$$

Dividing by $2(c^2 - ab)$,

$$x = a.$$

Substitute the value of x in (1).

Then,

$$(b + c)a + (b - c)y = 2ab.$$

Therefore,

$$(b - c)y = 2ab - ab - ac,$$
$$= a(b - c)$$

Dividing by $b - c$,

$$y = a.$$

Therefore,

$$x = y = a \quad \underline{Ans.}$$

Sometimes it is more convenient to solve for $\frac{1}{x}$ and $\frac{1}{y}$, as in the following example:

Example 4.

$$\frac{4}{x} - \frac{3}{y} = -3. \quad . \quad . \quad . \quad . \quad (1)$$
$$\frac{2}{x} + \frac{6}{y} = 1. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Multiply (1) by 2, and add (2), then

$$\frac{8}{x} + \frac{2}{x} = -6 + 1,$$
$$\frac{10}{x} = -5.$$

Divide by 5,

$$\frac{2}{x} = -1.$$

Therefore,

$$x = -2.$$

Again, multiply (2) by 2, and subtract (1), then

$$\frac{12}{y} + \frac{3}{y} = 2 + 3,$$
$$\frac{15}{y} = 5.$$

Divide by 5,

$$\frac{3}{y} = 1.$$

Therefore,

$$y = 3.$$

Solution is

$$\left.\begin{aligned} x &= -2 \\ y &= 3 \end{aligned}\right\} \underline{Ans.}$$

Beginners are often confused by the equations being given in the following form:

Example 5. Solve $3x + 4y - 6 = x - 2y - 8 = 5y - x + 16$.

Since

$$3x + 4y - 6 = x - 2y - 8,$$

we have

$$2x + 6y = -2. \quad . \quad . \quad . \quad . \quad (1)$$

and since

$$x - 2y - 8 = 5y - x + 16,$$
$$2x - 7y = 24. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

By solving (1) and (2) we obtain $x = 5$, $y = -2$.

50. **Let us now consider three simultaneous equations of the first degree containing three unknown quantities, x, y, and z. In the same way as already explained, we can eliminate one of the unknowns, say z, from two of the equations. Then, from one of these equations and the third equation, we can also eliminate z. We thus obtain two equations containing only two unknowns, x and y, and these can be solved as in the last Article.**

Example 1. Solve the equations,

$$2x + 3y + z = 7. \quad . \quad . \quad . \quad . \quad (1)$$
$$3x - y - 2z = 3. \quad . \quad . \quad . \quad . \quad (2)$$
$$x + y - 3z = 6. \quad . \quad . \quad . \quad . \quad (3)$$

Multiply (1) by 2, and add (2), then

$$7x + 5y = 17. \quad . \quad . \quad . \quad . \quad (4)$$

Multiply (1) by 3, and add (3), then

$$7x + 10y = 27. \quad . \quad . \quad . \quad . \quad (5)$$

By solving (4) and (5) we obtain

$$x = 1,\ y = 2.$$

Substitute these values in (1), then

$$2 + 6 + z = 7.$$

Therefore,

$$z = 7 - 6 - 2 = -1.$$

Thus, the solution is

$$x = 1,\ y = 2,\ z = -1 \quad \underline{Ans.}$$

Example 2. Solve the equations

$$\frac{1}{y} + \frac{1}{z} = 7. \quad . \quad . \quad . \quad . \quad (1)$$
$$\frac{1}{z} + \frac{1}{x} = 6. \quad . \quad . \quad . \quad . \quad (2)$$
$$\frac{1}{x} + \frac{1}{y} = 5. \quad . \quad . \quad . \quad . \quad (3)$$

Here, it is shorter to work as follows:

Add the three equations, then

$$2\left(\frac{1}{x} + \frac{1}{y} + \frac{1}{z}\right) = 18;$$

or,

$$\frac{1}{x} + \frac{1}{y} + \frac{1}{z} = 9. \quad . \quad . \quad . \quad . \quad (4)$$

Subtract (1) from (4), and we get

$$\frac{1}{x} = 2.$$

Therefore,

$$x = \tfrac{1}{2}.$$

Similarly, subtracting (2) and (3) in turn from (4), we get $\frac{1}{y} = 3$, and $\frac{1}{z} = 4$, so that $y = \frac{1}{3}$, $z = \frac{1}{4}$.

EXAMPLES 8

Solve the following equations.

1. $x + y = 8$, $x - y = 2$.

2. $2x + y = 2$, $x - 2y = 11$.

3. $3x - 4y = 1$, $5x + 3y = 21$

4. $2x = 9 - 3y$, $5y = 24 - 6x$.

5. $2x + 3y = 3x + 2y = 25$.

6. $\dfrac{5 + x}{3} = \dfrac{7 + y}{5} = \dfrac{9 + x + y}{7}$.

7. $\dfrac{x}{15} + \dfrac{y}{12} = \dfrac{x}{3} - \dfrac{y}{4} = 1$.

8. $\dfrac{x - y}{2} - \dfrac{3x - 4y}{5} = \dfrac{1}{2}$, $\dfrac{x}{3} - \dfrac{y}{2} = 2$.

9. $\dfrac{6}{x} - \dfrac{5}{y} = 8$, $\dfrac{4}{x} + \dfrac{3}{y} = -1$.

10. $2x - \dfrac{5}{y} = 3$, $x - \dfrac{6}{y} + 2 = 0$.

11. $ax + by = bx + ay = a^2 - b^2$.

12. $bx = ay$, $ax + by = a^2 + b^2$.

13. $y + z = 7$, $z + x = 5$, $x + y = 8$.

14. $2x - y + z = -4$, $3x + y + 2z = -2$, $x + y + z = 1$.

15. $\dfrac{1}{x} + \dfrac{1}{y} - \dfrac{1}{z} = 0$, $\dfrac{1}{x} - \dfrac{1}{y} + \dfrac{1}{z} = 4$, $\dfrac{5}{x} + \dfrac{1}{y} + \dfrac{1}{z} = 20$.

Answers to Algebra

EXAMPLES 6

1. $-11a^2b$.
2. $-6xy^2z$.
3. 21.
4. x^2yz^7.
5. $-3x^4 + 4x^2 - 2x$.
6. $2x + 3y - 4z$.
7. $-3a + 2b - 12c$.
8. $x + 1$.
9. $3x - 2$.
10. $1 - 2a + 3a^2 - 4a^3$.
11. $1 + x^2 + x^4 + x^6$.
12. $x^3 - ax^2 + a^2x - a^3$.
13. $a^2 + b^2 + c^2 - bc + ca + ab$.
14. $x - y$.
15. $(a - 1)^2 - b(a - 1) + b^2$.

BRICKWORK CONSTRUCTION

Arches. Centering for Arches and Vaults. Fireplaces. Chimney Flues and Stacks. Smoky Chimneys and Remedies

By Professor R. ELSEY SMITH

Racking Back. It is desirable that as far as possible all the walls of a building should proceed uniformly, so that at no time may there be any great difference in level between the top of any one wall and another. This cannot always be strictly followed, and where a change of level must occur between one part and another it is best to form this by *racking back* rather than by toothing. Racking back consists in setting back each course at the end of the higher wall a quarter brick beyond the course below [84, page 2265]. There is less liability of a settlement occurring in this case than when toothing is employed.

Temporary openings may be formed in brick walls for the passage to and fro of materials and workmen, or for similar purposes, by toothing the sides and forming the top with oversailing courses; such openings are often protected from damage by short boards fixed against the head.

Brick Arches. Where permanent openings occur in brick walls, they are usually covered by arches also formed of brick. In external walls, for the sake of appearance, no bearer or lintol of wood or iron is, as a rule, admissible; but on the inner part of the wall where the opening is often covered by joinery or plaster, the opening is covered by a horizontal beam termed a *lintol*, either of wood or concrete, and the arch is constructed above the lintol. Such arches, which are termed *relieving* or *discharging arches*, are, as a rule, segmental in form, and the skewbacks should be formed at the extreme end of the lintol; upon them a core is constructed in brickwork and mortar shaped so as to form a permanent centre to the arch which is built up upon it [97]. With concrete lintols, the upper surface is usually cast segmental in form, to receive the bricks of the arch directly.

Centering for Arches. Turning Pieces. Where arches have to be constructed over voids, without lintols, a temporary provision must be made to support them until the mortar is set. In the case of an arch above the reveals of a window, which, as a rule, is only half a brick thick on the soffit, if the rise be small enough to allow of a support being cut out of a single plank or board, this is usually done; a board 3 in. thick is used and the upper side is cut to the curve of the arch to be struck, and the under side is left horizontal; it is fixed upon supports nailed to the jambs of the opening, and is termed a *turning piece* [98]. The arch is constructed on the back of this, which is left in position till the brickwork is set.

If the soffit of the arch exceed half a brick in width, a single turning piece will not suffice, and a centre is formed; two boards are cut to the required shape from planks 1 in. to 1½ in. thick, placed at such a distance apart as corresponds to the width of the soffit, and secured to cross-pieces nailed below at each end; the upper surfaces have a series of wooden strips laid across and nailed to each. These strips are termed *laggings* [99].

For gauged work, the laggings are laid closely side by side, and the centre which is formed thus is termed *close-lagged*; for other classes of arches they are fixed at short intervals.

Built-up Centres. Where the rise of the arch is so great that the support cannot be cut out of a single board, the two sides must each be built up of two thicknesses of wood, so arranged as to break joint, and nailed or screwed together; the outer edges are cut to the curve of the required arch, and laggings are used as before [102].

In the case of arches of considerable rise and span, each of the side supports may require to be strongly framed and strutted in order to support the load; the form of centre will vary with that of the arch, which may be segmental [99], semicircular [102], pointed [101], or elliptical [100]; but, except in the case of arches of very long span, which sometimes have intermediate support, they should be designed so as to throw the weight of the centre and its load on to the two ends.

For large spans, in which the centres have to support very heavy loads, it will not suffice to rely on either nails or screws for holding the sides of the centre truly in form. The centres, then, instead of being built up in thicknesses, are cut from heavier timbers and are framed together where the timbers are joined; the timbers are disposed so as to form the side into a timber truss, rigid in form, which may be supported at the two ends; curved pieces must be added to the regular timbers forming the truss where necessary to give the form required for the arch.

Supporting Centres. It is only in the case of turning pieces and centres for quite small spans that the method of support already described will suffice. For heavier work, the centres are supported by struts, the lower ends of which rest on some solid support, such as the sill of a window opening or the threshold of a door. If the soffit be wide enough to require it, two struts must be provided on each side, with a cross-piece forming the head, which should come under the cross-piece below the end of the centre. Between these, two folding wedges [99] are inserted, and by their means the level of the centre is adjusted. When the brickwork is considered to be quite set these wedges are loosened, and the centre is dropped slightly, so that it is no longer in contact with the soffit; this is termed *easing the centre*, and should always take place prior to the final removal, which is termed *striking the centre*. After easing, the brickwork should be examined to see that no settlement or failure occurs before striking takes place.

Centres for Vaults. In the case of vaults, if the form is that of a plain, cylindrical, elliptical, or pointed one, it is practically treated like an arch with a very wide soffit, and in addition to the inner and outer frames, intermediate ones must be used to support the laggings.

If the vault be a groined one, formed by the intersection of two plain vaults, we shall require, in dealing with a square bay, four frames, all similar, for the four main faces; there must be in addition two diagonal frames intersecting at the centre, and marking the lines of intersection of the two vaults. If the vault be a large one intermediate frames may be introduced into each of the four compartments, to assist in supporting the laggings, which are laid on parallel to the axes of the two intersecting vaults, and meet above the diagonal frames.

Centres that have been struck may be re-used for other openings of the same size; they are, however, usually made of rough material, and are, as a rule, broken up when finished with.

Various Kinds of Brick Arches. Brick arches may be divided into (*a*) Common, or Rough arches [97], (*b*) Axed arches [98], and (*c*) Gauged arches [99], according to the treatment of the bricks of which they are formed. Common arches are used for all positions in rough and common work, and in better classes of work they are used for most positions in which the arch is covered by joinery or plaster.

In this form of arch the bricks are used without any cutting; it is usual to form all arches of a depth equal to at least two bricks laid on edge, and the depth is in all cases a multiple of 4½ in. In the case of all arches, except those in which the springing and the centre are at the same level, a *skewback* [99] must be formed to receive each end of the arch; this is prepared by cutting the bricks carefully to the necessary inclination, which is found by drawing a line from the centre from which the curve is struck to the point in the jamb from which the arch springs, and producing it.

Building the Arch. When the centre is in position a whole brick is laid on end parallel to the skewback, and forms the commencement of the arch at each side; one such brick occurs for every half-brick in the thickness of the soffit of the arch. Between these end bricks a row of bricks on edge is laid on the core, or wood centre, starting from the two sides and meeting at the centre of the arch. The bricks must be set out so that the mortar joint is fine at the lower edge of the brick and broad at the top to make up the excess of length in the extrados beyond that of the intrados. If the width of the soffit be a half-brick, only bats will have to be used; if it be one brick thick, headers are used; and beyond this thickness headers and bats are used as required so as to bond. Such a row of bricks in an arch, equal in height to a half-brick, is termed a *ring*, and the arch is described as a *two-ring* or *three-ring* arch, and so on, corresponding with a depth of two, three, or more half-bricks. When the first ring is completed as described the second ring is formed above it, but the radiating joints between the bricks will not coincide with those of the first ring, but break joint with them, and so also with subsequent rings.

As a rule, in architectural work it is rarely necessary to employ arches exceeding three rings in depth or four at the outside, but where deep arches are required, which only occurs with a wide span, there is sometimes a tendency for the rings to settle separately and to separate from each other. To obviate this, carefully bonded blocks of brick termed *bonding blocks* extending through the full depth of the arch are introduced at intervals in such arches [103], or blocks of stone may be substituted. Arches are occasionally constructed of one ring of bricks only in depth, but, as a rule, for any span up to 6 ft. a two-ring arch is employed; from this width up to 16 ft. a three-ring arch, and up to 24 ft. a four-ring arch.

In the case of arches of large span it may be necessary to load temporarily the crown of the centre to prevent it from being distorted by the pressure on the sides. In the case of a brick vault, if of barrel form it is treated like an arch with a wide soffit, but if groined great care must be taken in forming the groins, the bricks for which must be axed or rubbed to the required form. The construction is facilitated by the use of groining ribs, which are in reality independent arches, and these may be first constructed on their own centres and the general surface afterwards filled in on smaller separate centres; this system is usually adopted for stone vaults.

Arches in Axed and Gauged Work. Axed and gauged arches have the bricks prepared as already detailed for these two classes of work, the latter having fine putty joints, and being used for the best class of work, but they may be described together so far as general treatment is concerned.

The essential difference between both of them and a rough arch is that instead of using parallel-sided bricks the bricks are cut or rubbed into a wedge-shaped block termed a *voussoir* [105], while the joints are of uniform thickness throughout; and the excess in length of the extrados over that of the intrados is thus formed in the brick and not in the mortar joint [99], giving a greatly improved appearance to the work, but adding to its cost. Whatever the depth of the arch, each voussoir extends through the full depth, and is, where necessary, formed of two or more bricks in height, so that a complete bond may be secured; but the width of each voussoir at the extrados cannot exceed the width of a brick, and if the arch be deep the width at the intrados is much reduced.

Any of the ordinary forms of arch described under Rough Arches as capable of construction can be better formed for facing work either as axed or rubbed arches, and, in addition, the form known as a flat arch [104] may be utilised. This is a true arch, being in effect a portion cut

out of a larger segmental arch; the joints do not, however, radiate truly, but are formed by dividing both the extrados and intrados into such a number of equal divisions as will result in there being a central voussoir to the arch, and by drawing lines between the two series of points thus obtained.

Forming the Voussoirs. The voussoirs, if made up of two or more bricks in height, are cut or rubbed so as to give horizontal intermediate joints, and adjoining voussoirs are so jointed as to break joint [106]. It will be noticed that in cutting the bricks for a straight arch there is much waste [105], and where the depth of an arch is formed of a header and stretcher the actual depth is usually reduced to about 12 in. In semicircular, segmental, and pointed arches there need be no loss in depth; the width alone is reduced.

In forming the sides of such voussoirs it is usual to cut a groove V-shaped in section in gauged brickwork, so that when two voussoirs are placed in contact a small cavity is formed which will be filled during the process of setting by putty; this will harden, and assists to prevent the bricks from shifting laterally; this is termed a *joggled joint*.

Any such arch may have a moulding or group of mouldings run round the edge. Arches similar in form to axed arches may be formed with purpose-made bricks moulded to the required form, but if arches of various spans are struck with radii of different lengths each arch will require separate forms of bricks. It is desirable to use specially-made bricks for all articles executed in glazed brick, as the glazed surface is apt to be chipped in the process of cutting.

Fireplaces. In forming fireplaces it usually happens in modern houses that the walls are not thick enough to allow of the necessary recess being made in them, and where a fireplace is required, the wall has to be thickened. This may be done if the wall is external on the outside [107 C] by projecting the back beyond the outer face of the wall, or on the inside by projecting the front, termed the *chimney-breast*, into the room [107 B]; but in all cases where a wall is thickened for this purpose the footings need not be increased in depth but may have the same number of courses as in the adjoining wall.

In the case of a party wall, the projection must be into the room, and the back of the recess must be at least 4 in. from the centre of the party wall [107 D]. In the case of an internal wall the projection is usually into the room, and if two fireplaces occur back to back the projection is considerable; if they can be arranged side by side the projection may be reduced, but in such cases the fireplace will not come centrally in the breast [107 E].

In some cases it is convenient to form a fireplace across an angle of a room and two or more may occur in adjoining rooms so as to form a stack [107 F]. On an upper floor a chimney breast may be corbelled out from a wall, but the extent to which it projects should not exceed the thickness of the wall carrying it [88, page 2265].

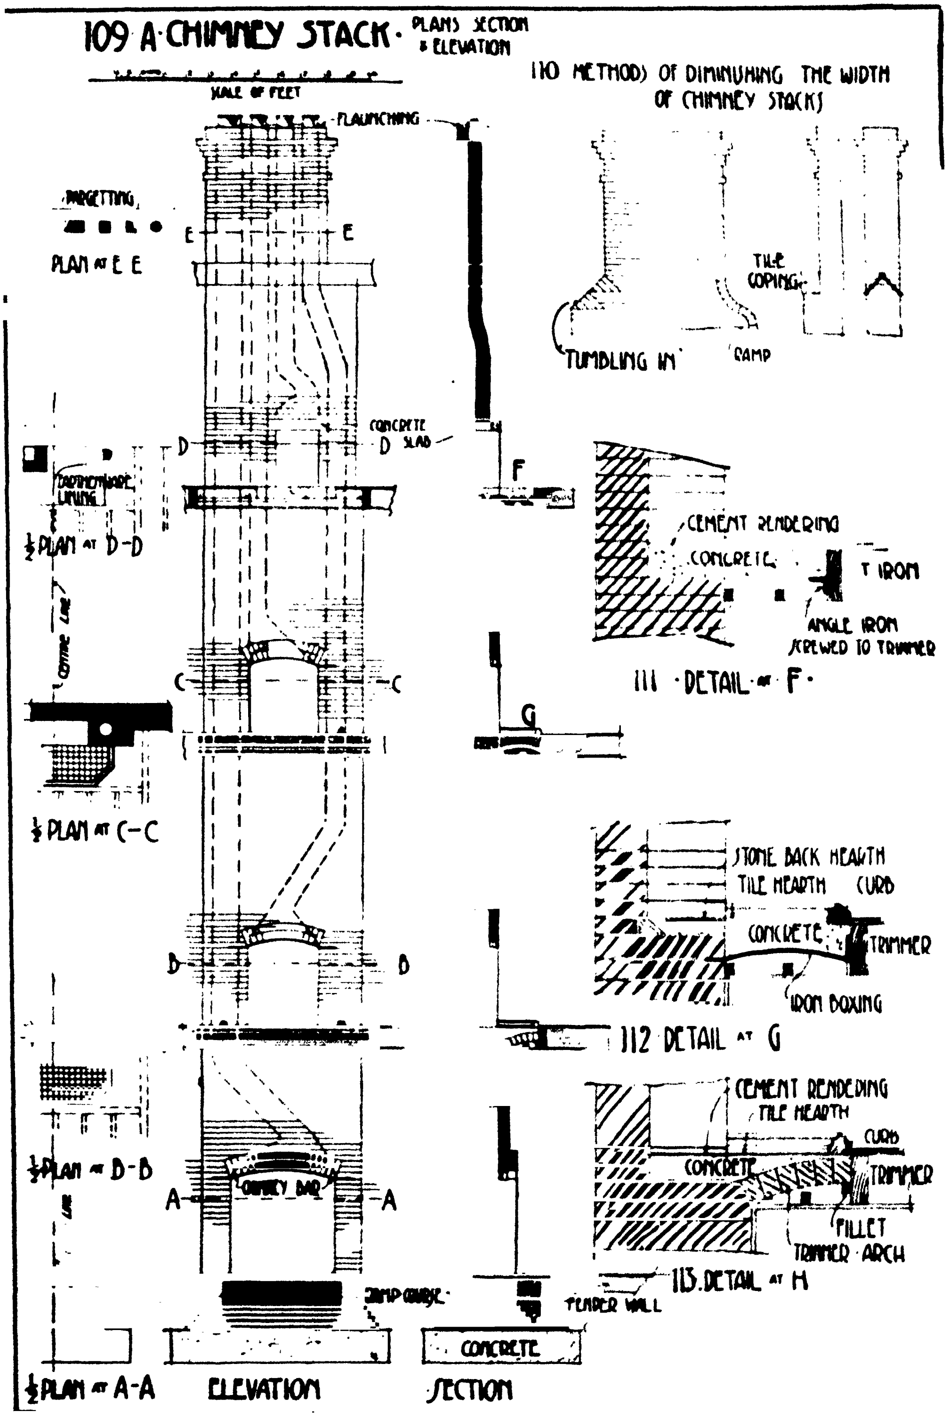
Forming the Hearth. The opening itself commences at least 3 in. below the floor level to give depth for a hearth of stone, cement, tiles, or other incombustible material, and the floor in front of the breast is *trimmed* if formed of timber [see CARPENTRY]—except on the lowest floor, where a fender wall may be formed. The space thus formed, which must extend 1 ft. 6 in. at least in front of the breast and 6 in. on each side of the opening, is occupied by a trimmer arch [113], or by a concrete bed supported on angle-irons spiked to the wood joints [111] or on an iron boxing [112].

The Fireplace Opening. The width and height of the opening vary with the kind of grate to be inserted. The top of the opening is rarely lower than 3 ft. from the floor, and may be considerably higher; the width should be at least 1 ft. 6 in. for the smallest bed-room grate, and about 3 ft. is usual, and even more is required, for many grates and ranges.

It is well to make the openings amply large; they may easily be filled in with brickwork afterwards, but it is troublesome to enlarge them. The opening is finished at the top by a rough brick arch, which is usually formed on a wrought-iron cambered bar, termed a *chimney bar*, about 2½ in. wide and ⅜ in. to ½ in. thick. The ends of this should be 9 in. long, and are split, one half bent up, the other down, to build into brick joints. Behind this arch, which carries the front of the breast and is usually only one-half brick in thickness, the sides are gathered over until the width is reduced to that of the flue which is to be carried up [109]. The flue may rise from the centre or from either side, and sometimes a ledge is formed to check down-draught [109 C–C]. In gathering over, the lower edges of the bricks are rough cut, so as to give an evenly-inclined surface. A block of concrete, perforated for the flue opening, may be substituted for the arch and gathering over [109 D–D].

Chimney Flues. Flues are usually 9 in. square or 9 in. by 14 in.—rarely larger for ordinary domestic work, but for the furnaces of hot-water apparatus and large cooking stoves larger flues may be required. They are surrounded throughout and separated from each other by brickwork at least one-half brick thick, and the separating or enclosing wall thus formed is termed a *wythe* [108]; every fireplace has a separate flue carried up to above the roof level. Where several flues occur close together, as when two or more fireplaces occur on a floor in close proximity, or a series of fireplaces are formed on successive floors, one above the other, they are combined into a block termed a *chimney stack* [109]; a special method of bonding is made use of, known as *chimney bond*, mainly composed of headers [108].

In forming flues, which may be carried up vertically, inclined at any angle, and even twisted on their axis if occasion require, great care is necessary to see that the proper sectional area is nowhere reduced; if this occur the flue is said to be *crippled*.



DETAILS OF CHIMNEY CONSTRUCTION

Any flue inclined at an angle flatter than 45 degrees requires to be provided with openings fitted with soot doors to facilitate sweeping. These *soot doors* consist of a small iron door and frame which is built into the side of the flue and which, when closed, is perfectly air-tight, but which can be opened for sweeping.

Parging and Coring. As the flue is formed it is carefully plastered on the inside—the process is termed *parging* or *pargeting* [108]; its object is to fill up all joints in the brickwork and to present a smooth, even internal surface to facilitate cleansing. The mortar used for parging usually has cow-dung mixed with it, in the proportion of three parts of dung to one part of lime, which forms a tough material less liable to crack than ordinary plaster. The construction of the flue requires careful watching to see that after parging no mortar droppings are allowed to fall on the finished surface, or, if they fall, are at once removed. The best plan is to block the opening below the level at which work is carried on by a bundle of shavings. On completion the flues are *cored* by passing a stiff wire brush down to clear away mortar droppings. Sometimes a solid wooden ball 8 in. in diameter is passed down every flue to ensure that no crippling has taken place. The top of the flue is often finished with a circular terra-cotta pot; this may be plain and stand only a few inches above the brickwork, its object being to protect the bricks round the top from damage when the chimney is swept; and in some cases flues are lined throughout with similar tubes, and do not then require parging. In other cases ornamental chimney-pots are employed, which may stand nearly their full height above the brickwork. The flat top of the brickwork is finished with a weathered cement surface, here termed *flaunching* [109], completely covering the top of the brickwork and finishing against the pot. Various special forms of pot have been designed to counteract down-draught in the flues, and consequent smoking fireplaces, some of which are of earthenware, but they include tall—sometimes bent—pipes of zinc known as *tall-boys*, formed with a flange at the bottom which rests on the brickwork, and is secured to it; some of these terminate with a rotating cowl.

Smoky Chimneys. It is often difficult to cure a smoky chimney if its condition is due to faulty construction or design, and the following points should be carefully attended to.

The flue must on no account be crippled. No connection with any second fireplace or stove should be made. The flue of a domestic fireplace should not be perfectly vertical throughout its height, but at some point it should be carried over to one side or the other to such an extent at least, that it is impossible to see sky through the flue from the fire opening. The top of the flue should not be finished below the level of the ridge of a high roof, or the wind, when in certain quarters, may sweep over the ridge down upon the chimney and create down-draught. A smoky chimney is not infrequently due to an inadequate supply of air to some other fireplace in which a good fire is burning, which, if unable to draw sufficient quantity of air from other sources, creates a down draught in the neighbouring flue; this may often be remedied by taking an air shaft from the outer air to the neighbourhood of the hearth.

The Use of Dampers. In forming flues from all kinds of furnaces, including coppers, and from kitchen ranges, a *damper* is usually built in; this consists of a sheet of iron the full width of the flue, which usually slides in an iron groove built into it, and when closed entirely blocks the flue; it can, however, be drawn out so as to leave it quite open or be fixed at any intermediate point, thus regulating the draught in the flue, the rate at which the fire burns, and the particular part of the range it is desired, at the time, to heat—*e.g.*, the oven, boiler, etc.

Setting Stoves. The actual stove or grate in which the fire is lighted must be built into the rough opening already described. Such stoves vary much in form; some are entirely formed of fireclay or brick, and most have a fireclay back and sides. They are placed in the recess, and should be set in brickwork, care being taken to fill up the back as well as the front, so that no cavity is left in which soot may accumulate, except in those cases in which a special warm air chamber is formed behind the stove, for introducing warm air into the room. Particular care must be taken to close the space between the front of the stove and the opening, as if this be not properly done smoke is liable to issue from it around the ornamental front or chimney-piece.

Setting Ranges. Ranges vary greatly in form and size. Some are termed self-setting, and merely require to be stood in a prepared opening with the flue pipe taken up into the chimney, the bottom of which may be closed. With many ranges the work is more complicated; they usually include a fire-box, which may be open or closed, and one or more ovens and a side or back boiler. In setting them it is necessary to construct the flue or flues from the fire-box to the chimney, so that the heat from the fire may be directed as desired, either mainly to heat the water in the boiler or to heat one of the ovens; each of these flues must, therefore, be controlled by a damper. This work is best executed in firebrick set in fireclay, but this is not absolutely necessary for small ranges: in all cases it is important that the instructions for forming the flues, which are supplied by the makers of many special forms of range, should have careful attention.

Furnace Flues. All flues from heating apparatus cooking stoves and ranges, except ranges in private houses, and similar flues in which a somewhat fierce and continuous heat is usual, should be surrounded by at least 9 in. of brickwork, and should be formed with firebrick if the heat is great. In most districts the conditions governing the construction of fireplaces, flues, ovens, factory chimneys, and similar works are dealt with by the local building regulations, which should be consulted.

THE ATOM'S WONDERFUL SECRET

The Death-bed of the Atom. The Wonderful Power it Gives off in Dying. Can We Use It? Will the Immeasurable Energies of the Atom Transform Society?

By Dr. C. W. SALEEBY

THE reader is besought not to imagine that the overwhelming and all-embracing significance of the corpuscular theory of matter has been completely indicated; but we may fairly take stock of our theory at this point, and notice how it accords with the statements which we made in leading up to and introducing it. We insisted upon the ultimate inseparableness of physics and chemistry, while pointing out that the physicist is mainly concerned with energy, and the chemist with energy only or mainly in the form which he calls chemical energy. We observed that the difficulties of chemistry are approaching solution at the hands of what is called physical chemistry, and we insisted upon that doctrine of the conservation of energy which, if it is really true, must necessarily be true in every chemical action.

What Have We Found? In the first place we have found that physics and chemistry are so much one that it is now almost ridiculous to speak of chemical energy. Chemical energy is electrical energy. In the second place we have found that the magnificent work of two chemists, Dalton and Mendeleef, has been crowned, and the greater part of the problems of chemistry have been solved, by the labours of a worker who is not a chemist at all, but a physicist. As for the law of the conservation of energy, we cannot yet point out its relations to the theory of Thomson, but we need only remind ourselves of what was lately said about negative electrons shot out from the atom of radium in order to see that the law of the conservation of matter requires revision. Now this law must apparently be regarded as a particular expression of the law of the conservation of energy. And if it be not true, what are we to say of the law which includes it and of which it constitutes a part? And how can we possibly assert it to be true in the same breath as that which serves us to say that negative electrons are shot out from unstable atoms such as that of radium, and go—whither? Do they disappear, are they annihilated, are they resolved into ether, the "mother of matter," or are they conserved as such?

Unstable Atoms. We are already in a position to understand that, in speaking of atoms, the terms *stable* and *unstable* are relative. The perfectly stable atom would, of course, be eternal; whereas the perfectly unstable atom would have no period of existence as an atom at all. Remembering this, however, we have to recognise that different types of atoms do vary enormously in their degree of stability, and it is obviously incumbent upon the new theory of matter to explain these differences if it can. It is impossible to discuss this subject, at the present time, in any complete way. The two most distinguished of the workers whose names have so often been mentioned since we began the discussion of the new chemistry, are now preparing books upon the subject, one dealing with the Transformation of the Elements and the other with the Corpuscular Theory of Matter. But these books cannot yet appear, because it is as yet impossible to reach the point at which even temporary finality is obtained. Since the greater part of the world of physicists and chemists are working at this subject new and important facts are being discovered about as rapidly as the old ones are being set down in print. Nevertheless, some provisional statement is already possible.

Atoms Within Atoms. Our previous discussion of the corpuscular theory of matter has enabled us to understand as ten years ago not the greatest of living chemists could have understood a large number of the great facts of chemistry. What amplification does it need in order to enable us to understand the extraordinary fact, discovered by Sir William Ramsay, that small atoms may be born from large ones?

One most important fact has been demonstrated by Professor Thomson. He shows that it is possible to substitute a system of corpuscles for one corpuscle in certain of the theoretical figures we have described. Thus, three corpuscles arranged in the triangular fashion already figured may exist within an atom and act as a whole just as one corpuscle would act.

Evidently, this is most important, for it at once gives us some inkling of the manner in which such a small atom as that of helium may spring, practically ready-made, from an atom of radium.

Movement of Electrons. Professor Thomson has also shown that important facts may be deduced from the movement of the electrons. In a paragraph in a previous section we commented briefly on the movement of the electrons in the atom and showed that the difficulties which it appears to introduce are not serious; but now we may amplify the statement and say that the movement of the electrons actually helps us in our attempt to explain the existence of unstable atoms. Let us take, for instance, the case of five Mayer magnets. It is found that there are two ways in which these may arrange themselves, sometimes as a pentagon and sometimes as a square with one corpuscle in the middle. Now, Professor Thomson has shown how the possibility of these two arrangements may be explained in the case of the very simple atom which we are imagining for purposes of study. When the electrons in such an atom are moving very rapidly, the arrangement will be that of the square with one corpuscle in the centre; but if their energy of movement is reduced, another arrangement becomes necessary, *and suddenly so*. There must be a certain *critical point*, above which one arrangement is necessary, whilst below it another is necessary.

The Death-bed of an Atom. If we conceive of an atom, parts of which are in movement, we have to ask whether any energy is being lost; there is a most extraordinary and significant parallel between this question and the questions as to the stability of the Solar System or of Saturn and his rings. We may note, by the way, that a Japanese physicist has made an interesting contribution to the theory of the radio-active atom by means of considerations derived from the study of the rings of Saturn.

Now, we have to believe that every atom is slowly losing its energy, this being the fundamental reason why it is *mortal*. In a lecture delivered a few days before these words were written, Professor J. J. Thomson spoke of the "death-bed of atoms," and pointed out that it is at the moment of death, so to speak, that the radium atom gives off the energy for which it is so famous. For ages it has slowly been losing its energy, and at last the point comes which we have called critical. An entirely new arrangement is necessary if the atom is to persist in any shape or form, and this involves the great reduction of the potential energy within the atom and the giving forth of a quantity of kinetic energy proportionate to that reduction. "The only tax the radium atom has to pay," says Professor Thomson, "is the death duty." The amount of kinetic energy which is evolved at the death-bed of the radium atom—after its long life, according to the latest estimates, of 1,200 years—is so great as to suffice abundantly for shooting out from the atom a certain number of its parts. We have only to suppose that among its parts are little systems of corpuscles, which are nowadays going by the name of *sub-atoms*, and which, if they could get free, are none other than atoms of helium.

A Key to a Mystery. We have already seen that the existence of such systems is quite possible, each of them being equivalent, in the structure of the atom, to one corpuscle, and acting as such. The so-called Alpha rays of radium consist, it is believed, of such sub-atoms, which are really equivalent to atoms of helium. These do not, indeed, consist of three corpuscles, as in the case of the sub-atomic system of the imaginary atom we have discussed, but probably of about 2,000 corpuscles (compare the atomic weight of helium and that of hydrogen).

Such an explanation as we have given is of the greatest value, in that it serves to explain what otherwise seems unintelligible. Why, we might ask, should an atom actually persist for twelve hundred years unchanged and then suddenly break down of its own accord? But now we have a key to this. We see that atoms do not persist unchanged; during all this period the atom, indeed, retains its form and structure, but it is slowly radiating energy. At last there comes the critical point at which the old arrangement is no longer stable—and then comes the crash. The reader will readily be able to supply analogies from his own experience. Why, it might be asked, should a man live at ease and in luxury for years, and then, all of a sudden, be thrown out of the society in which he lives and become a bankrupt and a pauper? The answer is, that though his circumstances have apparently not been changing, he has been living on his capital, radiating his potential energy, and at last a critical point is reached—and then comes the crash.

And now we are the better able to understand what we described on page 1916 as the "emanation" of radium. We saw that this element yields a gas, or emanation, which is not gaseous radium. We saw also that Sir William Ramsay has discovered that when the spectrum of this emanation is examined after an interval of four weeks or less the spectrum of helium is recognised. But lately we have passed beyond the simple view that the emanation of radium consists of a multitude of immature and unrecognisable helium atoms. That was hardly credible at any time. What, then, can we provisionally regard as the exact relation between the helium produced by radium and the emanation which it also produces?

The Emanation of Radium. It seems that the emanation itself consists of atoms which are of very large size indeed; not as large as the radium atom, however, though they belong to the same type. For the time being we may, perhaps, conceive—possibly in more simple terms than may ultimately be shown to be justified—that when the radium atom reaches its critical point, it breaks up into one or a number of alpha particles or helium atoms on the one hand, and one of these large emanation atoms on the other. These repeat, though with very great speed, the history of the original atom. Before long they break up, yielding more alpha particles or helium atoms, and a second type of emanation, which has been called emanation X. This again breaks down in its turn after a short time. There are in all probably five stages, as we have already seen, and we have already noted that the final atom—or, rather, the atom which is final for a time—seems to be that of lead. As for the first emanation, and the assertion that it consists of definite atoms of an absolutely distinctive and specific kind, we may note that Sir William Ramsay proposes to call it *ex-radio*—to indicate that this is an *element derived from radium*.

We have spoken of these various stages, but the reader must not imagine that there is any equivalence of time between them. The radium emanation undergoes its change in a matter of days. Emanation X takes only a few minutes; the next two stages not many minutes more; but the last stage, of which lead, perhaps, is the final product, is estimated to take centuries.

The Internal Energy of Radium. And now we are also in a position to add somewhat to our previous remarks concerning the energy of radium. We accept, of course, the disintegration theory, having been able to exclude the previous theories advanced by Sir William Crookes and by Lord Kelvin. The reader will scarcely need us to insist that when we discuss radium we are discussing principles which are true of atoms generally. On page 2029 it was said that "the eternal energies of radium can be manifested only at the cost of its internal energies . . . . it is only in virtue of the disintegration of its atoms that radium has been able to exercise its remarkable properties." There is not much need to insist again upon the enormous measure of the energy which is liberated by the disintegration of such a large atom as that of radium. Professor Thomson has quite recently made an important criticism upon the often-repeated statement that, say, half a pound of radium would drive a steamer across the Atlantic.

So it would, if it were possible to obtain half a pound of radium in one mass ; but it would take an extremely long time to do so, and for this reason : we have to conceive of the energy given out by radium as due to the breaking up of its atoms, *one after another*, as their internal arrangements reach the critical point. It is only on its death-bed, to vary the metaphor, that the radium atom parts with its fortune or power to any appreciable degree. The heat evolved by radium—or, rather, by the breaking up of such atoms in a mass of radium as may happen to break up during the period under observation—is believed to be mainly due to the alpha particles. The heat is evolved partly by the impact of these particles upon the rest of the radium, and partly by their impact upon surrounding objects. These alpha particles are thrown out from the emanation in all its successive stages. It has been calculated that about three-fourths of the heat produced by radium is thus due to its emanation, in virtue of the alpha particles produced.

The Power of a Thimbleful of Radium. We may quote from Professor R. K. Duncan, who has admirably arranged many of these remarkable and recently-discovered facts in his recent volume, "The New Knowledge." Professor Duncan says, on this point : "The volume of the emanation is infinitesimally small. From one gramme of radium compound the volume of the emanation evolved would not account to more than 1·3 of a cubic millimetre. This needle point of gas evolves enough heat per hour to raise the temperature of 75 grammes of water one degree. If it were possible to obtain one cubic centimetre—a thimbleful—of this emanation in the form of a gas, we should find that it possessed the power of emitting, altogether, over 7,000,000 calories of heat. This is more than sufficient to raise 15,000 pounds of water one degree, and all this heat from a thimbleful of an invisible gas! The important phase of this statement is that it is altogether outside of any hypothesis or theory. It is a simple, straightforward fact. Now, the heat evolved by exploding the same volume of hydrogen and oxygen mixed in the proportions required to form water is about two calories. We find, then, that the heat evolved by the radium emanation is over 3,500,000 times greater than that let loose by any known chemical reaction."

An Amazing Waste of Power. So much for the amazing measure of the energy which is involved in the structure of atoms. We may turn also to the smallest atom we know—that of hydrogen—the atom which contains much less energy than any other, and quote the estimate of Professor Thomson that "a gramme of hydrogen has within it energy sufficient to lift 1,000,000 tons through a height considerably exceeding 100 yards." In short, of all the energies which we know in Nature, those which we have long recognised, those extra- or inter-atomic energies which are constantly utilised in order to do the work of the world, are as nothing, are utterly insignificant and negligible compared with the *intra-atomic energy*—the energy which is within the atoms of matter, of which hitherto no use whatever has been made by man.

But before we pass on to consider, at some little length, the nature of the units of which atoms are composed, we may note briefly another consideration. As we all know, time was when society was based upon militarism, whereas to-day it is tending to become industrial. The military type of society is the oldest and, of course, the lowest. We have not yet reached the stage when society has become perfectly free from militarism ; but every one who thinks about man and his future looks forward to the day when society will have become completely industrialised and when war will have ceased for ever.

The Transformation of Society. But there are a few thinkers here and there who are inclined to question the common view that the industrial state of society is the best that can be conceived. At present, as for many ages past, we are engaged in an incessant strife with Nature, and the balance of power is at last coming to lie with "man's unconquerable mind." This is so because we are learning how to utilise natural powers. Nevertheless, an enormous proportion of all mankind are engaged, at one level or another, as "hewers of wood and drawers of water." This is as good as to say that our conquest of Nature is yet far from complete. But, if we are to judge by the past, we may believe that, in time to come, society will be no longer industrial, for the reason that industry, as we at present conceive it, will not be necessary. The fact of what are called "labour-saving devices" is one of the most important facts in the whole study of man. Even if we utilised to the full all the ordinary chemical energy which we employ in our furnaces, for instance, there would be a vast economy of labour. The time will unquestionably come when the work of the world, in nearly its whole extent, will be done, not by half-clad men digging coals out of mines or puddling iron, but by the simple pressing of a button. Society will have to pass through stages comparable to those represented by the introduction of the various mechanical inventions which have replaced, let us say, the old spinning loom.

The Immeasurable Energies of the Atom. It will seem, and unless we are more humane in the future than in the past it will indeed be, cruel to throw countless persons out of work by the introduction of new methods. But what are we to say if we remember the existence of the immeasurable and inexhaustible energies which lie within the atom—the atom which our very fathers thought to be dead and inert? In a small book published some time ago, the writer ventured to call the future social type the *spiritual*, as distinguished from the *militant* and the *industrial*. In so far as any forces other than spiritual forces can hasten the coming of this social type of the future, such forces are undoubtedly to be sought chiefly in the almost unimaginable transformation of all the material conditions of human life which will be achieved—which may, indeed, be made possible at any moment—by the discovery of some means of "tapping" the intra-atomic energies. Were this done there would be practically no longer any necessity for any of those labours of man which depend upon his need for turning to his own advantage the forces of nature. Let the reader ask what proportion of human work ultimately comes under this head, and then let him consider how human life must be transformed if such work be rendered unnecessary.

The Power of Every Breath We Draw. We have already referred to some of the uses of radium, but all that we have said is simply as nothing compared with the uses to which radium, and, indeed, all atoms whatsoever, may be put if we are able to harness them. As Professor Duncan picturesquely phrases it, "What man earnestly longs for he will obtain. If he knows that every breath of air he draws has, contained within itself, power enough to drive the workshops of the world, he will find out, somehow, some way of tapping that energy." There is nothing inherently impossible in the attempt. It is not a case of making a perpetual motion machine, nor of getting work under conditions which, according to the second law of thermodynamics [see PHYSICS], are incapable of yielding work. A very recent speculator suggests, and he is probably right, that the processes of intra-atomic change, unlike the processes of inter-atomic combination and dissociation, are irreversible. It would almost appear as if there were a precise parallelism between the laws of *heat and work* and the laws of *intra-atomic energy and work*. If this be so, we shall never be able to build up a radium atom from smaller atoms, except by somehow putting back into these smaller atoms all the tremendous energies which were dissipated when they were born. Instead of having work done by this process we should have to do an enormous amount of work in order to accomplish it.

But, on the other hand, there is no reason at all why we should not utilise the energies evolved in the breaking down of large atoms into small ones. The problem, indeed, is not so much how to utilise the intra-atomic energies as how to hasten their normal evolution. Our half-pound of radium would drive the liner across the Atlantic, but it might take ages and ages to do so, simply because a sufficient number of the radium atoms would not liberate their stored-up energies within a reasonable time. The question, then, is how to hasten the normal rate at which atoms disintegrate. In many parts of the world inquirers are now attacking this problem.

"Blowing Atoms to Bits." Not so long ago, for instance, when the present writer paid a visit to the laboratory which may perhaps be best indicated by describing it as the foremost physical laboratory in the world, he witnessed certain experiments with the Röntgen rays, the object of which was to "blow atoms to bits," if possible, and utilise the energies liberated by the explosion. That is a metaphorical manner of speech, but it is extraordinarily near the literal truth. We may fairly say that in practical physics at the present moment—or in practical chemistry (it does not matter which one says)—the most interesting and important inquiry is *how to blow atoms to bits*, thereby obtaining from them far more energy than one puts into them, just as a little match may make the beginnings of a very big blaze. After all, it is the old problem of transforming potential into kinetic energy, in a new dress. In setting a light to gunpowder so as to send off a cannon-ball, we are transforming into kinetic energy the potential energy contained and locked up *between* the atoms and *in* the molecules of the gunpowder and the oxygen of the atmosphere. Similarly, in attempting to blow atoms to bits by Röntgen rays or other means, we are seeking to transform into kinetic, or utilisable, energy, the potential energy which, as we have already seen, is contained, and contained to an almost incredible degree, *within* the atoms.

Professor Thomson's Latest Views. If the reader be wise he will welcome the quotation of Professor Thomson's own words, as nearly as possible, from the very last pronouncement he has made (March 24, 1906, at the Royal Institution), when these words are written. We quote or paraphrase the following:

In one hour one gramme of radium will give out sufficient heat to raise a gramme of water from freezing point to boiling point. On the average, a radium atom lives for more than 1,000 years, and it is only at the expiration of this period, when the atom becomes unstable, that its energy is liberated. This is a long period, even by our scale of reckoning, in which we take the rotation of the earth as the unit of time. If an atom of radium had an inhabitant, he would reckon on quite a different scale of time. Doubtless his unit would be the period of rotation of one of the corpuscles or systems of corpuscles in the atom, and it would correspond to a small fraction of the billionth—that is, the million millionth—part of a second. The life of a radium atom—

say, 1,200 years—might well appear, therefore, as an eternity to one of its inhabitants, thus raising the question "how is it that the radium atom, after existing for what—relatively to the rhythm of its own processes—is practically an infinity of time, at last collapses and suffers this extraordinary change which results in the giving off of energy?" This change is due to the loss of energy in the corpuscles and systems of corpuscles which rotate in the atom. The atom thus loses its state of moving equilibrium, as a top falls when the speed of its rotation is insufficient to preserve *its* moving equilibrium.

Can We Harness the Atom? Thus the energy of radium is displayed only at the deathbed of the radium atom. During its lifetime radium is a perfectly conventional element, so far as we know; it is only when it is ceasing to be radium that it begins to display its peculiar properties and gives off energy. So great is the amount of this energy that there is enough of it in a pinch of radium to carry an Atlantic liner across the Atlantic at full speed. Nevertheless, by no means at present known could a pinch of radium be made to do this, since, though it contains all this amount of energy, it gives it off with extreme slowness. In order to propel an Atlantic liner across the Atlantic in six days, 100 tons of radium would be required. The question is whether we shall be able to get at the internal energy of the atom *at a fast enough rate to be of practical value.* It should be well recognised that at present this is impossible—knowledge which will prevent the public from supporting bogus companies, the promotion of which is unfortunately one of the most frequent applications of science. A company has lately been started, or projected, which is to disintegrate the atoms of ordinary substances, with the consequent evolution of so much energy that coal will soon cease to be of any value!

And now, having considered the nature and possibilities of the atom as best we might, and having been put off again and again in our attempt to answer the root question of chemistry, which is the question of the nature of matter, we must turn to the study of those very units of which atoms are composed.

The Ultimate Units of Matter. We are now quite familiar with the Beta rays of radium and other bodies, and we are able to assert that they constitute the ultimate units. The Gamma rays we may ignore, since we believe them to consist merely of an ethereal wave motion like light and the Röntgen rays [see PHYSICS]; nor need we concern ourselves with the Alpha "rays," since we are now learning to call them alpha *particles*, and believe that they are really atomic and made up of the same constituents as the Beta rays themselves; nor does the recent discovery of the Delta rays of radium complicate the matter. We may concentrate ourselves entirely upon the constituents of the Beta rays. These are the ultimate units of matter. What we have already asserted about them may be easily summarised. They are probably identical in all their properties wherever found. Each either *carries* or *is* a charge of negative electricity. If the latter be true, then the ultimate units of the atoms of matter are atoms of electricity.

M. Poincaré's Remarkable Work. It is precisely this point that is now being determined. For a provisional answer to it we can scarcely do better than turn to certain French students, remembering that the history of science has taught us how lucid and brilliant are French men of science in these matters. M. Poincaré is known at this moment as the most distinguished combination of man of science and philosopher. His remarkable book, "Science and Hypothesis," was translated into English last year, and the reader who proposes to plumb to their depths the problems to which he has been introduced in this and its companion course will do well to acquaint himself with M. Poincaré's thinking. On page 165 (English translation—the Walter Scott Publishing Co., Ltd.), M. Poincaré says: "It is true that in the electrons the electricity is supported by a little—a very little—matter; in other words, they have mass." That is all that can be obtained on this particular point from this remarkable volume, but physicists have advanced since those words were written. Is it really the fact that the electricity of the electrons is supported by even a very little matter? It is certainly the fact that these electrons or corpuscles have mass, and, writing two or three years ago, M. Poincaré assumed, as everyone did assume, that wherever there was mass there was matter.

"The End of Matter." The question now, however, has taken a new form. Is it necessary to assume the existence of anything but electricity in order to explain the known mass or inertia of the electron or negatively electrified corpuscle? Are its mass and inertia anything more than electrical mass and electrical inertia? Perhaps, before we go further into the properties of the electron, we may state how this question appears at the present moment. M. Poincaré himself contributed an article upon it, in his brilliant French, to a recent number of "The Athenæum." He called that article by the sensational title, "La Fin de la Matière" (The End of Matter). It consisted of a masterly summary of the most recent work, the probable conclusion of which is that when sufficient of the mass and inertia of the electron have been allotted to satisfy the demands of electricity, there remains none whatever to be allotted to matter. Hence, M. Poincaré ventures to speak of the "end of matter." The root question of chemistry is the nature of matter, which has been regarded as an ultimate since men began to think, and the nature of which has been a subject of speculation for nearly three thousand years; and the answer of contemporary science is that matter is not an ultimate at all, but is a form of electrical phenomenon.

The author of a volume which has now become famous—"L'Evolution de la Matière"—has coined the phrase, "the dematerialisation of matter." Both this book and M. Poincaré's

"La Science et l'Hypothèse," are published in the "Bibliothèque de Philosophie Scientifique." Both have lately been translated, but are much preferable in the original for the reader of French. As Mr. Balfour lately put it, "matter has been not merely explained, but explained away." We must inquire into this.

The Fate of the Electron. A few pages back we raised the question, *apropos* of the doctrine of the conservation of matter, as to the fate of electrons. It was pointed out that we can no longer assert the doctrine of the conservation of matter to be true "in the same breath as that which serves us to say that negative electrons are shot out from unstable atoms such as that of radium, and go—whither? Do they disappear? Are they annihilated? Are they dissolved into ether, the 'Mother of Matter,' or are they conserved as such?" Now what help does M. Gustave Le Bon afford? If he cannot help us, we must wait for further information until Professor Thomson sums up the results of his recent researches. The reader will not expect us to be dogmatic. If he wants positive, dogmatic, unqualified statements, he must turn elsewhere—perhaps to the theologians, perhaps to the materialists, of thirty years ago. Contemporary physics is unfortunately unable to do anything more than lay certain facts before the student and suggest the possible interpretations of them. In the following paragraphs we shall freely paraphrase from M. Le Bon (French Edition, 1905, page 292, etc.).

It looks as if the last term in the dematerialisation of matter were the ether, into the bosom of which, so to speak, the negative electron shot out from a decomposing atom is plunged. What is the fate of the atom of electricity—the electron or negatively electrified corpuscle—after the dissociation of matter? Does it remain eternal, when matter no longer exists? If it retains its identity, for how long does it do so? And if not, what becomes of it? It is scarcely conceivable and is certainly quite improbable that these electrons retain their identity. They must lose their individual existence and disappear. If it be asked how, we may gain some understanding of it by considering the case of icebergs floating in the Polar oceans and retaining their individual identity until, at last, the temperature becomes warmer and they vanish and disappear in the ocean. "Such is, without doubt," says M. Le Bon, "the ultimate fate of the electric atom (the electron). When it has radiated all its energy it vanishes in the ether and is no more."

The Last Stage of Matter. Furthermore, M. Le Bon points out that in the course of the movements of electrons and their loss of energy various forms of vibrations of the ether are observed, such as the Hertzian waves, radiant heat, visible light, invisible ultra-violet light (to which we may add the Röntgen rays). The nature of all these is the same. "They are comparable to the waves of the ocean, which differ in size alone. These ethereal vibrations, always accompanying the electric atoms (electrons) very probably represent the form under which they vanish in radiating their energy." "Thus," says M. Le Bon, "the electron, having its own individuality and a definite and constant mass, must constitute the last stage but one in the disappearance of matter. The last will be represented by the vibrations of the ether—vibrations possessing no more permanent individuality than the waves which are formed in water when one throws in a stone and which soon vanish."

The last question, or almost the last, is this: How, exactly, can we conceive of the transformation of the electron into ethereal vibrations? There are a thousand considerations which conduce to the belief that these ultimate particles may be compared to whirlpools—the vortex atom theory of Lord Kelvin may well remain, though transferred from the atom to the electron. "The question, then, reduces itself to this: How can an eddy, or vortex, formed in a fluid, disappear in this fluid while producing waves in it? Thus stated, the problem is intelligible. In fact, one sees easily enough how an eddy formed in a liquid is able, when its equilibrium is troubled, to vanish while radiating the energy which it contains under the form of waves in the medium which surrounds it. It is in this fashion, for instance, that a waterspout formed in a liquid vortex loses its individuality and disappears in the ocean." We cannot do better than quote the paragraph with which M. Le Bon closes this section of his book.

The Atom's Secret. "It is, without doubt, so also with ethereal vibrations. They represent the last word in the dematerialisation of matter, that which precedes its final annihilation. After these fleeting vibrations the ether returns to a state of repose, and the matter has definitely disappeared. It has returned to that original non-existence whence only hundreds of millions of centuries and unknown forces can make it emerge anew as it already emerged remote ages before, and whither steal away into universal chaos the first traces of our universe."

And in taking leave of him we may also quote the final paragraph of his book:

"It is in this atomic universe, of which the nature was so long unknown, that we must seek the explanation of the greater part of the mysteries which surround us. The atom, which has not the eternity allotted to it by ancient beliefs, derives its power otherwise than from the properties of indestructibility and immutability. It is no longer an inert something, the blind sport of universal forces. On the contrary, it creates those forces. It is the veritable soul of all things. It holds in check energies which are the mainspring of the world and of its inhabitants. In spite of its insignificant minuteness, the atom, perhaps, holds all the secrets of infinite grandeur."

By WILLIAM R. COPE

Application of Borders. The proper application of Bands is to the enclosing of ceilings, walls, floors, panels, on certain architectural constructions, on the abacus and plinth of columns, and as a running ornament round the shaft of the latter. They are also used as the hem or border of garments, carpets, and other textiles, on the rims of plates or dishes, in typography, etc.

The Fret is specifically Greek ornament, and no doubt of textile origin. It was Greek vase-painting and architecture which gave rise to the variations of the pattern. Among the Romans the fret was used for mosaics on floors. The Middle Ages seldom used this pattern, but the Renaissance revived it in its ancient application, and made new combinations. The pattern is sometimes carried round a circle, an arrangement, however, which is not in accord with its character. Fig. **539** is an example of a Chinese fret, and **540** is a plait pattern. The centres of the circles in the double guilloche pattern in **552** are at the corners of an equilateral triangle, while in **554** they are at the corners of a square or diamond. [See pages 2321–2.]

The Greek wave *scroll*, or the evolute-spiral band, is shown in **558** to **560**. The line of this pattern divides the surface of the border into two parts, which in flat ornament are coloured differently. In plastic work, the lower part projects. This border is suitable for robes, shields, plates, friezes, cornices, tablets in architecture, and for other purposes. The rosette is sometimes introduced at the volute centres, and the interstices between the lines decorated with leaves and flowers or buds, as in **560**.

Examples of borders drawn on an equilateral triangular foundation are shown in **569** to **574**.

All-over Patterns on the Triangular Net Foundation. This foundation is easily constructed with the 60-degree set-square and T-square, and may be arranged in two ways, as in **508** and **509** [page 2320]. It is the readiest basis upon which the designer can form "drop" patterns. Many different shapes, such as the triangle, the rhombus or diamond, the hexagon, etc., all make perfectly fitting diapers upon this net, as shown in **561** to **568**. Many designs for parquetry and marquetry may be founded on these lines, and the ornament indicated by the various coloured tiles, stones, or pieces of wood used.

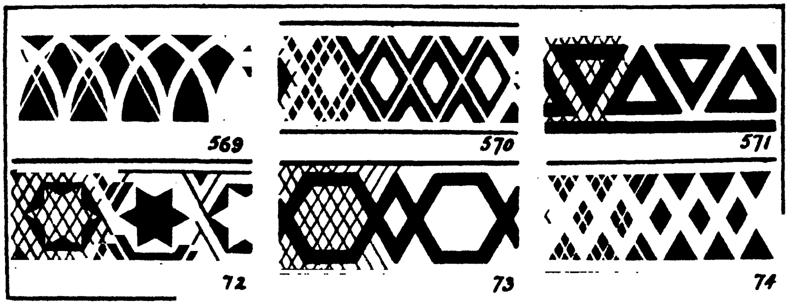
GREEK WAVE SCROLL. ALL-OVER PATTERNS ON TRIANGULAR FOUNDATIONS



BORDER PATTERNS ON TRIANGULAR FOUNDATIONS

Enclosed Ornament. This is ornament designed to fill a definite bounded space, such as a square, an oblong, a circle, etc., according to artistic rules, so that it fits exactly into this space alone. The space is sometimes called a "panel." Besides the square, oblong, and circle, other shapes, consisting of the regular polygons, the ellipse, the lunette or semicircle, various forms of the spandrel, the lozenge, and the triangle are most commonly used as panels.

Position of Panel Ornament. When the enclosed space has the design arranged symmetrically on both sides of one axis, the panel is suitable for a vertical position. When it is developed regularly in all directions from the centre of the shape, and is symmetrical to two or more axes (multi-symmetrical), the panel is suitable for a horizontal position, as in 575 to 595.

The Square Panel. The two diagonals and the two diameters are the lines on which the decoration of the square may naturally be based, and they form an eight-rayed star with rays alternately of unequal lengths, dividing the figure into eight equal spaces. Numerically, this mode of planning the decoration is predominant. The design shown in 575 is the Uraniscus, an ornament used in the coffers of Greek ceilings; the rays were gold on a blue ground. The patterns in 576 and 579 are examples of inlaid work of the fourteenth and fifteenth centuries. Fig. 578 is an arrangement suitable for ironwork, while 580 is the planning out for a tile design used in mediæval times.

but trefoliated forms were also added to this linework.

Another kind of decoration for squares is that in which it is subdivided into separate spaces, as in 581 to 589 and each space may receive independent ornament. It will be noticed that these are much used for panels in ceilings. The panelling in 586 is constructed by dividing the square into 16 smaller squares, and then drawing lines from the middle points of the sides of the large square at an angle of 60 degrees.

The Octagonal Panel. This may be easily constructed within the square as shown in 590 to 592, or within a circle. The diagonals and diameters intersecting again give a great variety of subdivisions.

The Hexagonal Panel. This is best constructed within a circle, and may be subdivided in a similar manner to the octagon. Many variations of the six-pointed star may thus be obtained.

The Circular Panel. This shape is usually subdivided into 3, 4, 5, 6, 8, 10, 12, or 16 similar parts, by lines radiating from the centre; or it may be divided into zones, with each belt-like band decorated independently. The subdivision formed by means of arcs, as in 593 and 595, are very suitable for this shape, especially when required for tracery.

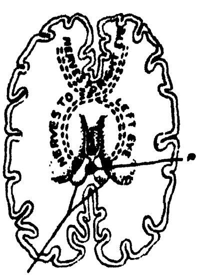
THE EYE

The Eyeball and its Protection. The Eye like a Camera. The Iris and the Pupil. How Colours are Distinguished. Long and Short Sight

By Dr. A. T. SCHOFIELD

The Eye like a Photographic Lens. We have dealt with the main functions of the brain, and it now remains for us to consider the special senses and the faculty of speech. We begin with the eye, and the first thing we should clearly understand about it is that it does not see, and cannot see, any more than a photographic camera. In the latter, the object is focussed through a lens into a dark box, at the back of which it is pictured on a sensitive plate; but the camera does not see—it is the man behind the camera who sees. He peers through the ground glass at the back, and sees the object mirrored there. Of course, it may be objected that this is necessarily so, since sight is an attribute of life, and the camera is not alive. This is true, but nevertheless the illustration is of force because it is difficult to realise that the eye by itself is exactly like the inanimate camera, alive though it be, only receiving and reflecting the images, and that it is the brain behind the eye which really sees.



126. SECTION OF THE BRAIN
Showing position of pineal gland (*p*) and nerves of sight

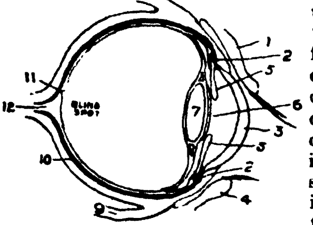
The Real Centre of Sight. We have already noted that the "optic lobes," the real centres of sight by which we see, lie in the base of the brain [126, 133] just in front of the pons in the medulla. These lobes are directly connected, each of them with both eyes; and if one lobe be destroyed, total blindness of the opposite eye ensues, while if both are destroyed, complete blindness ensues, though all images are pictured on the two eyes or "cameras" as perfectly as ever, and that, too, by vital, and not merely chemical processes. This is seen in cases of disease destroying these lobes, which are therefore the psychic centres of sight. In exactly the same way the ear does not hear, nor the tongue taste, nor the nose smell.

The Eyeball and its Protection. Each eyeball is a hollow, flattened sphere, about 1¾ in. in diameter, lying in a pyramidal bony cavity known as the orbit. This is filled with fat, in which the eyeball rests as on a cushion, and revolves freely in a capsule without the least friction [127]. This orbit protects the eyeball from any ordinary injury in front, where it is very strong; but behind the eye its walls are very thin, so that the point of an umbrella thrust into the socket might easily enter the brain, and yet an iron hat-peg nearly 3 in. long has been extracted from the orbit, where it had lain for some days without causing much inconvenience! Another patient, some time after threshing wheat, suffered some pain in the orbit, and discovered in the corner of the eye a grain of wheat that had shot forth a tiny green sprout. The eyeball is still further protected by the *wo eyelids*, the upper of which, at any approach of danger, closes down involuntarily in front of the eye. Above and on the outer side lies the *lachrymal gland*, and every time the eye winks a tear is squeezed out of it and sweeps across the eye, washing all impurities away, and leaves the eye by a little duct leading into the nose. This takes place about five times a minute. Only when the tears are rapidly excreted under the influence of emotion do they roll over the lower lid and we are said to "cry." Tears are not secreted before six months—infants, therefore, do not really "cry."

Six muscles are attached to the sides of the eyeball by small white tendons, so as to pull it in every direction. One of these tendons which rolls the eye upwards runs through a perfect little pulley in the top of the orbit [128].

It is of the utmost importance that both eyes should move together, and this has been secured by a similar nerve supply to both eyes—an arrangement that is generally, but, as we shall see, not always successful. When it fails, we squint.

Why Both Eyes See the Same Object. The two eyes are, of course, the sole cause of *stereoscopic vision*, by which two pictures from slightly different points of view are combined into one, thus giving the sense of space or solidity—in short, truly picturing the world of three dimensions in which we live. Had we but one eye, we should see everything in the same plane in two dimensions only, and find it very difficult to understand solidity.



127. DIAGRAM OF THE EYEBALL
1. Upper eyelid 2. White of eye 3. Window of eye, or cornea 4. Lower eyelid 5. Iris 6. Pupil 7. Lens 8. Upper, and 9. Lower, muscle of eyeball 10. Black screen behind retina 11. Yellow spot 12. Nerve of sight

In front of the eyeball is inserted a circular, transparent membrane called the *cornea* [129], through which all light enters the interior. It is apparently "let into" the eyeball, exactly as a watch-glass is let into the face of a watch. It is really, with the rest of the outer coat of the eyeball—called the sclerotic—comprised of very tough fibrous tissue. In the cornea alone the cells are perfectly transparent, and are arranged in perfectly parallel rows, and there are no blood-vessels.

Mechanism of the Eyeball. It is difficult, as we look at this transparent, glass-like structure, to believe it is composed of about 100 layers of living cells. The surface consists of a false skin, exactly like the epidermis of the body, with the same active life going on every hour. The substance beneath is a mass of transparent, flat, fibrous bands, with irregular spaces between them. These spaces are filled with white corpuscles from the blood—a matter of great interest, because here their movements can be most closely watched during life. If a little aniline dye be injected into the leg, after a time some part of the cornea may be tinged with the colour through white corpuscles which have absorbed it into their bodies having made their way to the eye.

It is evident that on the perfect transparency of the cornea all sight depends, for at the present time, when once the cornea has become opaque, no means is known of restoring the sight. The eyelids are lined with a delicate skin called the conjunctiva, which is continued all over the eyeball, and whose anterior layers form the epidermis of the cornea.

128. THE TWO EYEBALLS FROM ABOVE, SHOWING THE MUSCLES AND BLOOD-VESSELS

Nasal artery

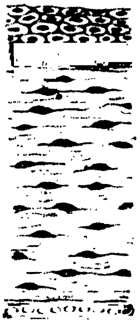
The Iris and the Pupil. On the inner side of the cornea is a *small chamber*—like the space between the watch-glass and the watch—filled with a *clear watery fluid*, called the aqueous humour. The chamber is bounded behind by the iris, a coloured muscle with a contractile circular aperture or diaphragm, through which the image to be seen enters the eyeball. The two irides are not always of the same colour, and brown spots are frequently seen upon them. In albinos they are pink, because, having no colour, the blood is seen through them ; and as too much light thus enters the eye, these individuals see best in the dusk. The pupil or black hole in the middle of the eye varies in size according to the amount of light and distance of the object. It cuts off all superfluous light, so that the image is defined sharply and clearly. The muscles of the *iris* can contract the aperture or *pupil* to a pinhole, or expand it to one-third of an inch. The pupil only looks black because the interior of the eyeball is dark. Its average size is ⅙ in., and the centres of the pupils should be 2⅓ in. apart. In a dark room, or when looking at objects a long way off, the pupil is expanded, and it is contracted in bright light or when looking at near objects. This far-away look, from gazing at distant objects, by expanding the pupils, increases the beauty and "depth" of the eye, and is sometimes cultivated artificially, and often depicted in sketches of female heads. Certain drugs, such as atropine, enlarge the pupil, also fear, weakness, and alcohol. Other drugs, such as the Calabar bean and opium, contract the pupil. In men, the muscle acts involuntarily, but animals that prey by night, as cats and owls, can use it voluntarily.

The Focus of the Eye. Just behind the "iris," or coloured curtain of the eye, lies the *crystalline lens* [130], by which all images are brought to a focus on the back of the eye. This lens is *bi-convex*, and about half an inch in diameter, and its effect can be seen by focussing any view or object on a white sheet of paper, with a similar lens. The distance of the lens from the paper requisite to produce a clear focus on the paper is determined by the distance of the object, the whole variation being, however, very slight, the length of the focal distance between an object 20 ft. off and one 4 in. being only $\frac{1}{10}$ in. In the camera, where the image of the sitter has to pass through the lens on to the ground-glass or sensitive plate at the back, the length of the focus is adjusted by moving the lens backwards or forwards with a screw until the focal length is arrived at, and a clear, sharp, reversed image of the object is obtained. In the eye the lens is fixed, and the sensitive screen that receives every image is also fixed, about ¾ in. behind it.

Near and Distant Objects. To understand the focussing of the eye, one or two points must now be made clear. All vision is divided into "far" and "near." All objects over 20 ft. are "far" or "distant," all others are "near." In the normal eye, the rays of light from each object over 20 ft. distant being parallel, are naturally focussed on the eye by the lens, the only adjustment needed being, as we have shown, an enlargement of the pupil to admit more light. Objects under 20 ft. require what is called accommodation, as rays of light from these are divergent. This is an operation performed unconsciously and exactly, according to the distance of the objective from the eye. Whether an object is 30 ft. away, or 30,000,000 miles, no change in the eye is needed to see it, but a great change in the eye is needed to see an object at 10 ft., and another at 2 ft. The change required is threefold; the pupil is contracted and the two eyeballs converge—a slight inward squint—according to the nearness of the object, and lastly the lens becomes increasingly convex according to the same law. This is necessitated in the eye when the focal distance is fixed, but is not required in the camera when the focal distance can be altered instead. The more convex the lens, the shorter the focal distance, and the lens is therefore automatically altered according to the distance from the eye of any object under 20 ft.



129. CORNEA, OR WINDOW OF THE EYE
Magnified section

The lens is of almost perfect elasticity, and a thin membrane stretched across the front of it keeps the anterior surface flatter than the posterior, and a special set of muscles instinctively relaxes this membrane to let the front of the lens become more convex as required. Accommodation, or adjustment of vision, for objects under 20 ft. is therefore a threefold muscular action—namely, contraction of pupils, convergence of eyeballs, and convexity of lens.

Behind the lens is the interior of the eyeball, filled with a *delicate crystalline jelly*, through which the light passes to the back. All the light comes through the aperture in the iris, which, whatever colour it may be on the front, is itself black on the inside, to prevent any rays penetrating into the eye, except by the pupil.

The Nerve to the Brain. The nerve that passes from the brain into the eyeball to the centre of sight is like a stalk to the eye, and is as thick as a small slate-pencil. It does not enter the eye exactly at the back, but $\frac{1}{10}$ in. to the inner or nasal side, and then spreads out into a thin film called the *retina*, $\frac{1}{80}$ in. thick, all over the inside of the eyeball, excepting the anterior third, where no image nor light can ever come. It does not lie immediately in contact with the white "sclerotic" coat of the eyeball itself, for between the two is a layer of cells called the *choroid*, having the appearance of *black velvet*, so full are they of black pigment, which forms an admirable background for the transparent nerve film that lies on it, while it allows no ray of light to pass through.

This nerve film [131], thin as it looks, consists of some dozen most complicated layers of cells of various kinds, the innermost, next the choroid, being a layer of so-called "*rods and cones*." The rods are filled with a delicate fluid called the visual purple, which is bleached as the light falls on it. They are supposed to give the picture looked at in black and white, while the cones are supposed to be connected with the colour sense, certain of them responding to the red rays, others to the blue, and others to the green or yellow. The retina itself is quite transparent during life, but cloudy and pink after death. Opposite the centre of the lens, at the very spot where all objects are focussed that are directly looked at, there is an elevation called the *macula lutea*, or yellow spot. The optic nerve enters $\frac{1}{10}$ in. to the inner side of this spot. In this spot, all the layers disappear except the cones, and sensitiveness decreases with the distances from it. Thus, 5° away, the sight is only $\frac{1}{4}$ as acute; at 10°, $\frac{1}{15}$; at 20°, $\frac{1}{40}$; at 30°, $\frac{1}{70}$; and at 40°, only $\frac{1}{200}$. Beyond this, vision is imperfect. Every nerve fibre that enters the eyeball by the optic nerve is connected with about seven cones and pigment cells, and 100 rods.

On the rods and cones that lie innermost against the black choroid coat every object from the external world is thus temporarily photographed.

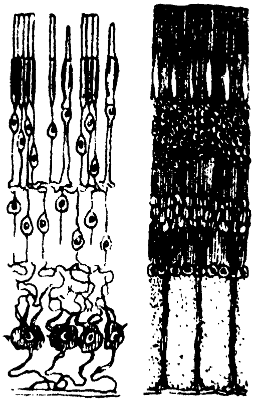
We can "see" many things at once, but we can only "look" at one object at a time—that is, focus it on the yellow spot.

The Blind Spot. As we have seen, *the optic nerve itself cannot receive any image*, and as there can be no retina where it enters the eyeball, so part of every image we see is lost, as if a black hole was punched out of it; only we never notice this, any more than the fact that everything we see is upside down, because we have long since learned instinctively not to notice the small blank part, and also to reverse the visual image in the mind. But that the "blind spot" exists is proved, as is well known, by closing the left eye, looking steadily at this cross [132], and slowly raising the head up to a certain point; the black dot will be seen as well while you still gaze at the cross, but at a certain height it will suddenly disappear. At this height, while the cross is impressed on the yellow spot, the black dot is just on the optic nerve, and hence is not seen, proving the nerve of sight itself to be blind, and only able to receive objects through the retina.

130. LENS OF THE EYE
1. Lens adjusted for far, 2. for near, objects 3. Cornea
4. Conjunctiva 5. Sclerotic
6. Choroid 7. Ciliary process
8. Suspensory ligament 9. Iris
10. Anterior chamber

The eye gazing at any bright object soon gets exhausted, for the object is not merely mirrored, but positively photographed, as we have shown, upon it. If a rabbit be killed in front of a window in a bright light, and its retina examined, the bars of the window can be seen bleached upon it. Hence, for a time after coming into the house on a dazzling day we are quite blind.

And here let us once more compare the eye with the camera. A photographic artist standing by a sensitive camera, looks at the object with his eye, and we may observe the simultaneous process going on in the two. At the same instant that he takes the cap off the camera he may open his own eye wide, and thus takes off the cap or eyelid. The light reflected from the object now streams in at the cornea in the eye and at the opening in the camera. Passing backward in both, the first thing met with in each is the bi-convex lens. This serves to gather up the diverging lines of light from objects under 20 ft., or parallel rays from objects over, and causes them to converge to a focus as they pass in to the sensitive plate in the camera, or the retina of the eye. On each, they at once bleach the object reversed. Here, in the camera, the process ends; in the eyes, the image is at once conveyed along the optic nerve to the centre in the brain, which "sees" it.



Separated nerve fibres

Section of retina

131. RETINA, OR FILM OF NERVE OF SIGHT SPREAD OVER INSIDE OF EYEBALL

Showing rods and cones and nerve cells and fibres

The eye has one great advantage over a camera, in having a *curved* retina equidistant in every part from the lens. The camera has a *flat plate* and can only therefore perfectly focus a very small part at the same time.

How the Eye sees Colours. Light itself consists in the movement of *luminous waves of ether* travelling at a speed varying from 446 to 667 billions of feet per second, *red waves* being the *slowest*, and *violet* the *most rapid*, *green* occupying a *middle place*. This perhaps accounts for the rest that green gives to the eye, for being of a middle tone its vibrations are not so fatiguing as those that are very rapid or very slow. The variations in light waves are, however, much more limited than sound waves. Each colour is caused by waves of light of a definite rapidity, and certain cones seem able to take up only the slowest, or red rays; others the faster, or green or yellow; others the fastest, or blue and violet. The solution of the puzzle on our walls of "Pears' Soap" is thus quite obvious. We stare at the great red letters until all our red cones are exhausted, and we cannot see with them; then, if we turn our eyes away, though the whole image of the "Pears'" is fixed for a time on the retina, the red cones being exhausted, we only have the blue and yellow left, and hence see it as green. Of course, if the red were not exhausted, and we turned away, we should not see it in any colour at all, for all colours together make white light.

Colour-blindness. Colour-blindness is not at all uncommon, and in some cases is most dangerous, particularly in railway employees, for red-blindness, which is the most common in engine-drivers and others, might lead to fatal consequences. Prolonged smoking of strong tobacco often causes such red-blindness, so that no difference can be seen between a red rose and its leaf. Colour-sight, like all else in the body, increases by practice, the cones being, of course, living cells. It is found to be *better in women than men*, as they have for generations been occupied with the study and discrimination of bright colours. The bright light of sunshine is 60,000 times stronger than the moon at full, or a bright candle at a distance of one yard, and soon exhausts the eye.

Keen Vision. Acuteness of vision is dependent not only on a perfect eye-camera, but is partly psychical and due to long practice, and is therefore, like all other qualities, hereditary.

Four thousand years ago the Arabs named a small star in the tail of the Great Bear, now just visible, "Saidak," or the Tester (of sight), and to-day their vision is wonderfully keen. Indian guides have been known to distinguish the figure of a man against the skyline eighteen miles away. Of course, in such an instance, a great deal depends on the amount of light falling on the object, and on the purity of the air. Dwellers in towns, on the other hand, have very short sight, as have those who have to gaze entirely at close objects.

Results of Disuse. The eye also wastes away if not used, like any other organ, as is seen in the eyeless insects and spiders in the great caves of Kentucky. It also enlarges to an enormous size when the light is poor, as in those fish that swim at great depths. It is curious to note that in soles and all flat fish one of the eyes travels through the head. These fish are constructed to swim vertically like all others, but they soon begin to lie and to swim flat on one side. At first, soles, like salmon or trout, had a right and left eye, but it is obvious that with constantly lying on the side the lower eye would always be buried in the mud. The eye itself travels through the head and comes out by the side of the other eye; so that all flat fish have two eyes on the one (upper) side.

INTELLECTUAL FREEDOM

Rational Freedom and Openness of Mind. Life must have Definite Aims. The Bearing of History on Life. Contact with Affairs a Cure for Intolerance

By HAROLD BEGBIE

MR. JOHN MORLEY has written contemptuously of "our lofty new idea of rational freedom as freedom from conviction, and of emancipation of understanding as emancipation from the duty of settling whether important propositions are true or false."

One of the most certain effects of study upon the mind is determination of opinion. A man cannot read an admired author without receiving something of the bias of his master. As we proceed in our studies, so we are moulding and fixing our opinions. It seems almost impossible that a man should read diligently and remain in precisely the same state of mind concerning the direct and indirect subjects of his inquiries.

And yet rational freedom is to be desired. Not the rational freedom of the man of the world, with "his inexhaustible patience of abuses that only torment others; his apologetic word for beliefs that may, perhaps, not be so precisely true as one might wish, and institutions that are not altogether so useful as some might think possible"; not this false and unworthy freedom of reason, but the true and just openness of mind which effectually preserves the student from the fierce and cramping effects of bigotry.

The problem, therefore, is how to cultivate this rational freedom and openness of mind, and at the same time confirm and strengthen resolution, energy, and devotion to principles. What we have set ourselves to compose is a suggestion which has for its end intellectual freedom combined with energy of action.

The Broad Principles of Life. Now, there are certain broad and definite principles of life which happily admit of no equivocation, and upon which every man—if he questions himself—will find that he holds opinions quite as definite. For instance, a man will know whether he believes in the humanitarian principle of doing unto others as he would they should do unto him; or, whether he believes in the laws of the forest, whereby selfishness becomes an intelligent creed. On these broad and definite principles of life it is necessary that the opinions he holds should be boldly and faithfully announced in his own mind. He may be uncertain whether Conservatism or Liberalism better serve the interest of the humanitarian principle; but he must not be in two minds as to whether Freedom is better than Tyranny, or Equal Rights better than the Law of the Strongest. On the broad principle he must hold definite opinions. There is no question here of bigotry or intolerance; it is a question of aim, of direction, a question of aspiration and character.

If a man conscientiously believes that the humanitarian principle is a delusion, and that all the travail and heavy labour of the world are due to man's sentimental notion of striving to introduce love into a brute universe, he cannot be accused of intolerance in holding this opinion and striving for its acceptance in the world. But if a man holding this opinion is moved by compassion to give money for the relief of distress, or puts his own life at the risk in order to save a life which can bestow no possible advantage upon his—then, even while his tolerance is praised, he confesses himself neither intellectually free nor courageous in his character.

Need of Definite Aim in Life. In the beginning, then, we suggest that it is above all things necessary for a man to determine his attitude towards life. Before he picks up the tools of energy he must know what he would fashion. Even if he finds himself unable to determine whether the world was made consciously or unconsciously, even if he finds himself unwilling to subscribe to the idea of a life beyond the grave, still he must determine within himself—if he would save his life from perilous drifting—what it is he earnestly desires to do with his existence. In other words, he must be aware within himself of a direction and an aim in his life. He must possess a general principle of conduct.

Given this direction and aim in life, we must proceed to discover how study and experience may be prevented from hardening the intellect in any one single inclination. For instance, if a man entertains humanitarian principles, we must discover how he may save himself from an exclusive devotion to any one particular panacea for human ills—such as the gospel of a particular sect of Christianity, or the creed of the philosophical vegetarian.

The Study of History Ensures Tolerance. The first of all studies which makes for a wise tolerance is History. The path of human progress is strewn with the skeletons of forgotten causes. No one particular view of a thing has ever held an eternal field. Men are for ever setting up banners and erecting temples, and for ever the movement of humanity leaves those tattered flags and those ruined temples far behind the march of to-day. The reason is obvious, and an apprehension of this reason is the surest safeguard of an open mind and freedom of intellect. Life is a gradual revelation of truth. We penetrate every day a little further into the mysteries of Nature. At no single time has truth made an absolute revelation of itself. The outlook of every day is a little wider. To build a temple with every fresh aspect of truth is natural—for enthusiasm is one of the driving forces of the world—but it is unphilosophical, it is irrational, and it must fail. Humanity can no more stop at what is called "Darwinism" than it could stop at the Inquisition. The philosophy of Plato can no more satisfy the cravings of human reason than the counsels of Lord Chesterfield. To believe that any one set of opinions can ever hold the field is to say that knowledge is exhausted, that it has discovered all there is to be discovered, and that the race can progress no further. Intelligent reading of history, then, will always check the student from erecting hasty temples to his partial apprehensions of truth. He will balance his enthusiasm for to-day with his respect for the possibilities of to-morrow. He will never be in a hurry.

False Intellectual Freedom. But it is quite possible that the student of history may find himself the victim of that false freedom of intellect so eloquently condemned by Mr. Morley. He may be so paralysed by the tremendous spectacle of lost causes and ruined aspirations strewn across the road of universal history, that he will sit with folded hands and profess himself unable to strike any blow in the conflict of his day. He will have an open mind, but an empty mind. He will have no fixed opinions ; he will have no opinion at all.

The way out from such a paralysis of intellectual energy lies, we think, in a devotion to the practical affairs of life. The student who remains in his closet is always in danger of this paralysis. But let him come from his books into the actual world of existence, let him make himself acquainted with the lives of men and women, let him, above all things, endeavour to see the problems of existence from the standpoint of those whose circumstances are different from his own, and it is certain that he will shake off his paralysis of will, and find himself determined in certain definite directions regarding his opinions and his conduct.

The Secret of Voltaire's Power. "Voltaire's books," says Mr. Morley, "would not have been the power they were but for this constant desire of his to come into the closest contact with the practical affairs of the world. He who has never left the life of a recluse, drawing an income from the Funds and living in a remote garden, constructing past, present, and future out of his own consciousness, is not qualified either to lead mankind safely or to think in the cause of human affairs correctly. Every page of Voltaire has the bracing air of the life of the world in it, and the instinct which led him to seek the society of the conspicuous actors in the great scene was essentially a right one."

"Let no one," says the sage Guicciardini, "trust so entirely to natural prudence as to persuade himself that it will suffice to guide him without help from experience. For there is no man, however prudent, who has been employed in affairs but has had cause to know that experience leads us to many results we never could have reached by the force of natural intelligence alone."

We believe, then, that the student who would combine intellectual freedom with energy of opinion must be something of a man of affairs. He must trust less to intuition and more to actual experience. He must know more of life than of literature. It is one of the regrettable characteristics of modern life that municipal authority should lie so very largely in the hands of ill-educated, and therefore prejudiced people ; while the scholar and student remain behind the scenes, wrong thinkers and wrong citizens. An active realisation of the duties of citizenship would contribute more to the authority of the philosophers than many libraries of their meditations.

There is, however, as we may see from the biographies of famous men, always a danger of intolerance. The student who takes part in civic life, the philosopher who becomes a statesman, do not always preserve their intellectual freedom. Their intolerance may not be a danger to the State, and may not prove a serious bar in the path of their own intellectual progress, but it cannot be said of them with propriety that they enjoy ample freedom of intellect. They have subjects on which they are "cranks" ; they have opinions on which they are bigots.

Intellectual Freedom a Rare Virtue. It may be said at once that there will always be people in the world ready to describe as a crank any man whose opinions differ from their own : but we are ready to admit that intellectual freedom is one of the rarest of virtues in human society. And, further, when we examine the question more closely we are puzzled to decide whether the intolerants have not done rather more for human progress than the tolerants. Wherefore the conclusion we come to is in the nature of a compromise. We believe that a man may enjoy intellectual freedom under a general and steadfast principle of conduct ; we hold that a study of history and acquaintance with actual life conduces to this end ; and we argue that intense devotion to a set of opinions may be justified, even when it seems to fetter freedom of intellect, if its effect upon the world is in harmony with a beneficent principle of conduct.

To realise that every day we approach nearer to the truth of which we shall never actually lay human hands upon is to convince the mind of the extreme value of modesty and tolerance ; and this is the true benefit of intellectual freedom. Howsoever eagerly and firmly we may embrace one set of convictions, if we are modest in our beliefs and tolerant towards the beliefs of other people, we shall not greatly miss the calm and serenity of intellectual freedom, the inexpressible satisfaction of an open mind.

RUSSIA

Russia's Inland Sea Coast. Flat Surface, and Large River Basins. Climate. Zones of Vegetation. Industries. Baltic Lands and Poland

By Dr. A. J. HERBERTSON and F. D. HERBERTSON, B.A.

Boundaries. European Russia (2,100,000 sq. miles) stretches eastwards from an artificially determined land frontier with Norway, Sweden, Germany, Austria-Hungary, and Rumania, to the confines of Asia. Its northern shores are washed by the Arctic Ocean and its gulf, the White Sea, on which is Archangel, long the only Russian port, closed by ice for half the year. On the Baltic Sea, in the north-west, are the ports of St. Petersburg, Revel, Libau, and Riga, of which only Libau is always open. In the south the Black Sea, with Odessa as its chief port, communicates with the Mediterranean, an advantage lessened by the fact that Constantinople commands the only exit and entrance. The land-locked Caspian facilitates communication and trade with Persia on the southern shore and with the Russian dominions in Central Asia.

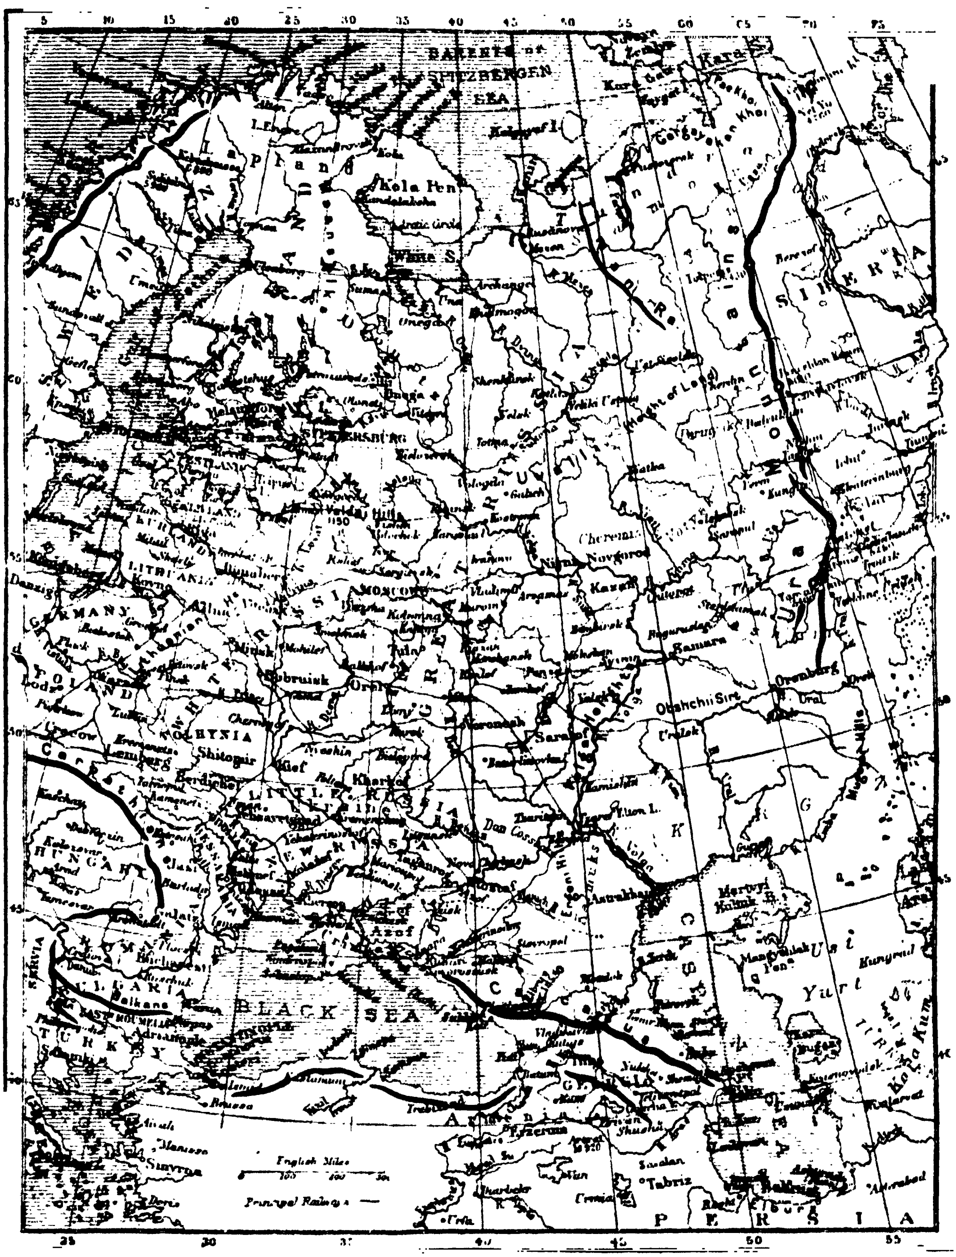
A Surface Nearly Level. Russia has no striking contrasts of highland and lowland. It is an undulating plain, generally over 300 feet above sea level, crossed by a broad belt of higher ground which rises in the Valdai Hills to 1,100 feet, and forms the divide between the rivers flowing to the Arctic and those flowing to the Baltic, Black, and Caspian Seas. The Urals, which form part of the boundary between Europe and Asia, consist in the south of parallel ridges rising to 4,500 ft., but are less definite in the north, where, in spite of an elevation of 5,000 ft., they may be regarded as a continuation of the central belt of elevation. They are extraordinarily rich in minerals, including iron, and the forests supply all the timber needed for smelting it, as well as an immense surplus for export. This is made up into huge rafts, which are floated down the Kama and its tributaries to the Volga. The Caucasus, which forms the frontier of Europe between the Black and Caspian Seas, rises in Elbruz to 18,000 ft., and contains many extinct volcanoes. The scenery rivals that of the Alps in beauty, glacier and snow-peak rising above the beech forests and pastures which clothe the lower slopes.

Russia's Big Waterways. The rivers of Russia, though they diverge to widely distant seas, rise near each other at the same level, and often in the same vast marshes. Flowing across a region with no strongly marked natural features, their courses often approach each other, so that it is easy to traverse the country from end to end by water, the boats being carried for a short distance across the low, marshy land which separates one river from another. Canals connect the various rivers, so that there is a continuous waterway, for example, between St. Petersburg on the Baltic and Astrakhan on the Caspian.

Look out on the map the sources of the North Dvina, flowing to the Arctic; the Volga, flowing first east and then south, round the base of low heights, and across sunken plains to the Caspian, which lies below sea-level; the Western Dvina, flowing west to the Gulf of Finland; and the Dnieper, which flows south to the Black Sea, and helps to drain the great Pripet swamp, the rest of whose waters are carried to the Baltic by the Vistula. Between the Vistula and the Western Dvina is the Niemen, whose chief tributary rises only a few miles from a tributary of the Dnieper. All these rivers are near each other either at their sources or in other parts of their course. The country between the Dnieper and the Volga is drained to the Sea of Azov by the Don and its tributary, the Donetz. Notice the close resemblance between the lower courses of the Dnieper, Don, and Donetz, and how this eastern trend brings the Don within 40 miles of the Volga, rendering communication between the Caspian and Black Seas easy and cheap. The other rivers to note are those from the Urals, the Pechora, flowing north to the Arctic, and the Ural, south to the Caspian, forming part of the boundary of Europe.

Climate. In Russia we have a typical continental climate, dry and extreme, especially in the east. The rainfall of Russia is everywhere scanty, except in the Western Caucasus, and the districts round the Caspian are almost rainless. Look back at the climate maps of Europe. The great southern sweep of the winter isotherms means that everywhere the winter is long and severe. A hundred years ago Russia utterly defeated the great Napoleon by the aid of two invincible generals, General January and General February. There are no high hills to break the winter gales which sweep across the country with irresistible force, making the winters of such neighbouring countries as Rumania much more severe than if mountains intervened. Snow covers the whole country for many weeks, and the frosts become more intense and protracted as we go east. The rivers are frozen for six months in the north, three or four in the centre, and for eight or ten weeks in the south. At Astrakhan, in the latitude of Lyons, the ice lasts 90 days; while at Warsaw, on the Vistula, which, though much further north, is also further west, it lasts only 77.

The Coming of Spring. After this long winter, spring comes and goes in a flash. "The sound of many waters is heard everywhere as the melting snow flows down to the low-lying fields, converting miles of country into a shallow lake, in which the farms and villages built on a little higher ground seem an archipelago of islands. For ten days or a fortnight all communication



102. RUSSIA

ceases with the outer world." Almost immediately it is the height of summer. "A few days after the frost has disappeared the trees are all in leaf. Within the space of a few yards I have often seen the ground a blaze of flowers and butterflies and dragonflies skimming over heaps of snow that the fierce rays of the sun have not had time to melt." The summer is hotter in the south than in the north, and in the east than the west. So precious is the summer that many peasants, all of whom own a fraction of the soil, hasten from the factories where they have spent the winter to sow and reap from dawn to dusk, returning to the mills when the leaves begin to fall and the night frosts tell of returning winter.

Zones of Vegetation. Russia extends across the whole breadth of Europe, and has all those zones of vegetation which we have so far seen only separately. In the north is the tundra, but on a vaster scale than in Norway or Sweden. Across a desolate, treeless, marshy plain, buried half the year in snow, the rivers creep to the Arctic. Fishing in river and sea is important in summer, and in winter timber is cut, and fur animals are hunted in the forest to the south. The preparation of timber, tar, pitch, furs and tallow from the forests, and of train oil from the Arctic fisheries are the chief occupations. Archangel, the port of the tundra, trades in all these.

The coniferous forests of Sweden and the deciduous forests of Central Europe are found in Russia on a magnificent scale. Villages and towns are built in the clearings, and all around lies the boundless forest, with the river as its highway. [108.]

South of the forest belt are the agricultural lands, passing into rich steppes like those of Hungary and Rumania, but infinitely greater in extent. On the margin, the landscape is broken by small woods, but the true steppe is treeless, and grass or ploughed lands extend to the horizon. Much of the steppe is covered with rich black earth of inexhaustible fertility. Its beauty and fascination for the steppe dwellers have already been described.

Finally, beyond the steppes comes what is not found elsewhere in Europe, the beginning of the desert in the dry, salt plains round the Caspian. This region is as thinly peopled as the tundra, and offers as little to its inhabitants.

Occupations. The uniformity of the surface has its counterpart in the lives of the people, among whom we find little of that diversity which marks Western Europe. The occupations of the tundra depend on the fisheries and the forest. In the forest regions the forest industries are carried on, with agriculture in the clearings. Agriculture is all important south of the forest zone during the summer, and the cultivated steppes form one of the granaries of the world. In winter those peasants who remain in their villages carry on many industries, often of a highly-skilled character, supplying all peasant and many middle-class requirements. For this, among other reasons, large industrial towns are confined to the coalfields. These are found in Central Russia, round Moscow and Tula, the Sheffield of Russia, in the Donetz basin, and in Poland. The chief manufactures are distilling and brewing, cotton manufacture, sugar refining, tanning and flour milling.

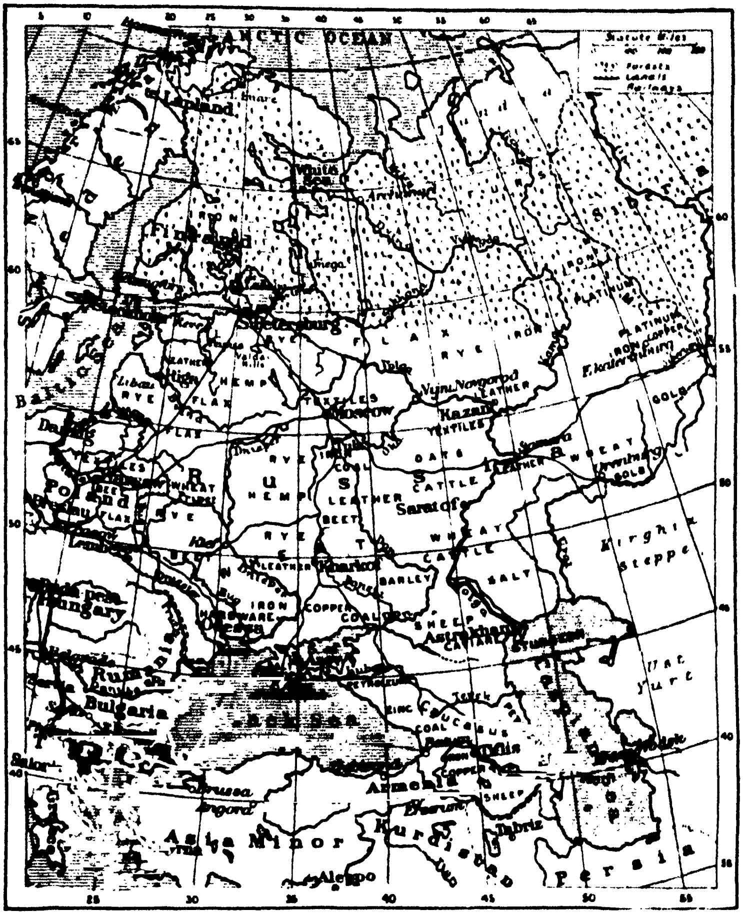
The Baltic Lands. Around the Baltic lies a region of pine-woods and innumerable lakes, large, like Ladoga (7,000 sq. miles) and Onega (3,800 sq. miles), or quite small. Lying north of Ladoga and the Gulf of Finland is the grand duchy of Finland, with thousands of lakes. It is inhabited by a people whose intelligence, love of liberty, and prosperity, in spite of difficult natural conditions, recall the Swiss. The capital is Helsingfors, a handsome city opposite Revel. The latter is one of the ports of the Russian Baltic provinces, also a region of lakes and forests, with flax, hemp and hardier cereals in the clearings. These Baltic provinces are not Russian in blood, and to Russianise them St. Petersburg was built among the desolate swamps at the mouth of the Neva, the foundations being laid on piles. The Neva is frozen for nearly five months in the year. The city is handsomely built on both banks of the river, and is made picturesque by the coloured and gilded clustered domes of the cathedral of St. Isaac and of many churches. Kronstadt, at the head of the Gulf of Finland, strongly fortified, is the station of the Russian Navy, and an outport for the capital.

Poland. Poland, also non-Russian both in blood and sympathies, resembles the Baltic provinces in the north, but rises in the south to a densely-forested plateau, intersected by deep ravines. Agriculture and cattle breeding are important, and the forests supply timber, which is floated down the Vistula in great rafts. Coal and other minerals are abundant in the south, where industries are growing rapidly. Lodz, with a large proportion of Germans and Jews, has hundreds of cotton-mills, woollen factories, steam flour-mills, breweries, machine shops, etc. Warsaw, on the Vistula, the old capital, carries on many industries, and with its command of routes in all directions is bound to become one of the most important cities in Europe.

The Dnieper Basin. This lies partly in the unproductive zone of Central Russia, partly in the rich Black Earth belt. The sugar beet is grown round Kief, the chief city of the Dnieper, with sugar refineries, tanneries, woollen manufactures, and flour-mills, all manufacturing the products of the Dnieper basin. Kherson is the port. West of the Dnieper are Nikolaief, on the Bug, with similar manufactures, and Odessa, the commercial metropolis of the region, built on the high edge of the steppe above the Black Sea, and doing an enormous trade in the produce of the Black Earth region. Bessarabia in the south-west resembles Rumania, and has many vineyards.

The Don Basin. The basin of the Don and its tributary the Donetz lies chiefly in the steppe region. Kharkof is the centre of the industrial region on the Donetz coalfield, which draws its raw materials from the steppes. The traffic in goods carried by the Don to Rostof and Taganrog, the ports of the Sea of Azof, is very great, including petroleum and other products of the Caspian, and timber from the Urals, which reach it by way of the Volga. The Crimea, united to the mainland by the narrow isthmus of Perekop, is a steppe land in the north, with a very extreme climate. In the south it rises to the Yaila Mountains (5,000 ft.), the southern valleys of which have the Mediterranean climate, and produce good wine.

The Volga Basin. The Volga, the largest river of Europe, 2,300 miles long, drains with its tributaries a region as large as the British Isles, France and Germany. It rises in marshes in the Valdai hills, and is navigable from Tver, where it leaves the hills. Nijni Novgorod, the scene of an enormous annual



103. INDUSTRIAL MAP OF RUSSIA

fair, where the products of east and west are exchanged, is built where the Oka comes in on the right bank, having flowed, like the main stream, through a densely-forested region. On a tributary of the Oka is Moscow, the real centre of Russia, with its picturesque Kremlin Hill, crowned with palaces and churches. Further south are the industrial centres of Tula and Orel, on the central coalfield. Below the confluence of the Oka the Volga flows between a high right and a low left bank. Kazan, the former Tartar capital, is on the river only in times of flood. Its industries are characteristic of the steppe towns, including tallow, soap and candle works, and tanneries, utilising the produce of the vast herds of the steppe lands, also flour and starch mills, supplied by the agricultural steppes. The Kama, the chief tributary on the left bank, flows through the mining region of the forested Urals, and brings down the produce of Siberia, including immense quantities of grain and timber, as well as tea from the Far East. The lower course of the Volga is through the wheat land of the steppe. Windmills for grinding flour are everywhere, the country being too flat for water-power. Steam flour milling is also important. The chief towns are Samara, on the left bank, and Saratov and Tsaritsin, on the right. At the latter town, from which a short railway goes to the Don, the river is already 60 ft. below the sea-level. A large branch, the Akhtuba, flows parallel to the main stream, communicating with it across marshy land by many channels. The delta begins 40 miles above Astrakhan, and is crossed by 200 distributaries. The valuable sturgeon and seal fisheries of the Lower Volga and Caspian employ thousands of men. Caviar, a delicacy made from sturgeon roe, is largely exported from Astrakhan. The chief occupation of the Caspian steppes, away from the river, is cattle keeping, carried on by nomadic tribes, who live in tents and follow their flocks and herds from pasture to pasture. Only along the river-banks and in the delta is there a settled population. Astrakhan is the Caspian port of the Volga, and an excellent system of canals in north-west Russia has converted St. Petersburg into its Baltic port, thus giving this immense but remote region an outlet to the markets of Central Europe.

POSITIONS

The Seven Positions. Half Positions. Higher Notes. "Portamento." Extensions. Four-string Chords. Double Stopping

By ALGERNON ROSE

HITHERTO the hand has been in the normal position, the top C having been played by stretching up the little finger. The hand is said to be in the *First Position* throughout the compass of two octaves up to top B, when so situated that the first finger gives the nearest note above that of any open string. But, above the top C, obtained by an extra stretch of the fourth finger, the left hand of the violinist can stop ten extra notes on each string, those of the two upper strings being of the better quality. The method of fingering this considerable range of additional notes should therefore be thoroughly understood.

Shift the left hand towards the bridge a note higher than it has been when playing in the normal position. Be careful to keep the wrist well down, and to let the fingers fall perpendicularly on the strings. The hand is now in the *Second Position*, and the third finger no longer represents C on the fourth string, the second finger having become identified with that note. Amongst amateur fiddlers it is a custom to go from the first to the third position without taking the trouble to learn the second. This is a slack habit. The second position is as easy and beautiful as the third, and the student who devotes attention to the former will later on reap his reward.

It will be observed now that the open strings are no longer utilised. The sooner the student gets accustomed to fingering every note the better. On account of the different quality of the open notes, good players use them sparingly, and only when the tones they produce are otherwise unobtainable. We give in Ex. 13 the fingering of the four strings in the second position.

When the hand is shifted up a note still further, it is in the *Third Position*. In this the ball of the left hand rests against the shoulder of the violin, the thumb acting as a brake, so that the hand does not go too far. On approaching the bridge, the student will perceive that the notes lie nearer each other. In consequence, the fingers, especially when stopping

semitones, come closer together. Should the player's fingers be thick at the tip, he may therefore, before stopping a half-tone, find it necessary to remove the finger which gave the preceding note. Here, then, the C on the fourth string is stopped by the first finger instead of the second, as in the previous position. [Ex. 14.]

Playing the same scale in the *Fourth Position*, and beginning on the note D, this will be stopped by the first instead of the second finger, as before. [Ex. 15.]

In fingering the four strings correctly, the left hand must now be more elevated over the edge of the belly and the elbow carried further under the violin, so that the fingers may be able to reach the G string easily. Hold the instrument firmly with the chin. According to the size of the player's hand, so does the thumb leave the neck of the fiddle and cling to the rim of the belly close to the fingerboard, and in returning to a lower position the thumb always leads the way.

By slipping the hand up so that the first finger takes the place lately occupied by the second, the fingering changes to that of the *Fifth Position*. [Ex. 16.]

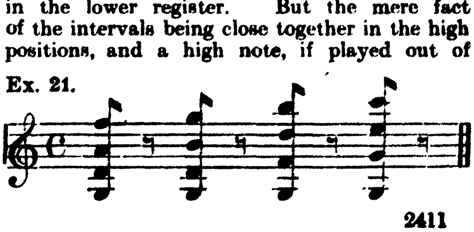
In the *Sixth Position*, instead of the index finger representing the first E on the fourth string, the hand moves up and the first finger presses down F. [Ex. 17.]

The top note on the first string is now G (fourth ledger line above staff). This is the limit within which second violin parts in orchestral music are written.

The highest recognised position in violin playing is the *Seventh*, the top note of which is A, and the three semitones above—namely, A♯, B and C—indicate the limit at which stopped notes may be played on the fingerboard. In this position, then, the first finger gives G on the fourth string, exactly an octave above the pitch of the open note. [Ex. 18.]

High Notes. Save that the higher the hand goes up the closer the intervals become, there should be, with practice, little more difficulty in fingering the seventh than the second position. The reason that the higher shifts are generally regarded as presenting great difficulty is chiefly owing to want of familiarity with them, most violin music being written in the lower register. But the mere fact of the intervals being close together in the high positions, and a high note, if played out of

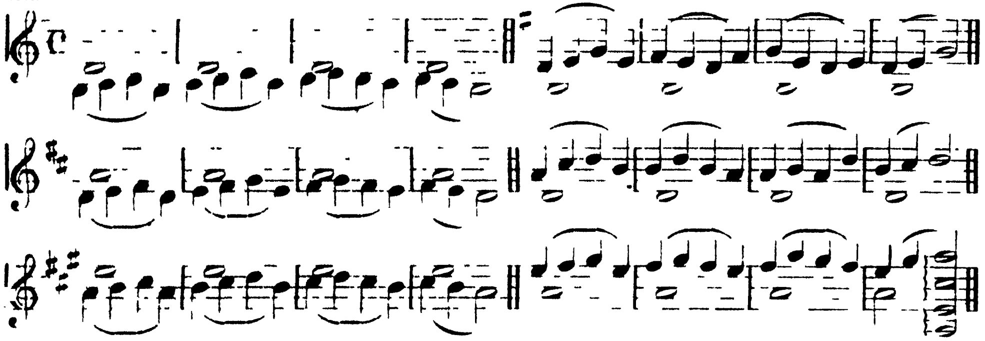
Ex. 21.



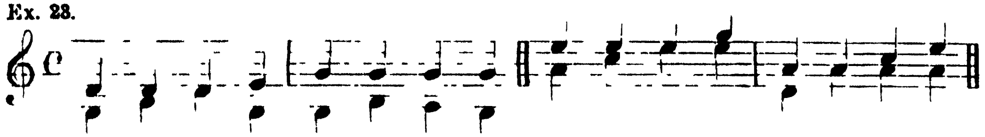
tone, being more noticeable than a low one, should stimulate the student to distribute his technical exercises at least equally over the seven positions. For the violinist to confine his attention to the first and third positions puts him on a level with the piano strummer, who is familiar only with the three centre octaves of the keyboard, and neglects all the other notes.

It is not so much the difficulty in fingering as the trouble of reading many ledger lines that causes the student to hold aloof from trying to master the top shifts. It is only by practice that great violinists have learnt to read with equal facility notes high up above the staff as those on it. Considering that the violoncello player must make himself conversant with the bass and tenor clefs as well as the treble staff, the task of the violinist is, comparatively, far less difficult. All that has to be done is for the pupil to proceed systematically in his daily practice, and gradually he will find himself becoming as familiar with the top of the compass as the bottom.

Ex. 22.



Ex. 23.



Half Position. In addition to the seven positions described, there is what the Italians call the "Mezza Manica," literally the "half neck," or shift. This is not midway between the first and second positions, as might be surmised. That would make it a position and a half. Instead, the fingers stop the notes one degree *lower* than the first position. The hand must therefore be kept quite close to the nut of the fingerboard. Let the first finger touch the E string peg. In music intended for the half position, a low F♮ is not infrequently written. The student observing it for the first time may think that it is below the compass of the violin, and that he will have to let down his fourth string slightly to play it.

He may save himself the trouble. If he adds mentally two semitones to F♮, he will understand that the sound required is only the open G. After familiarising himself with the fingering of the seven positions, the self-instructor may regard the half position as an unnecessary complication, unless he realises that great players have found it enhances the tone of certain melodies, which, like those in the key of B major, lie naturally within the half position. Like many other perplexities in violin playing, it is not so impracticable as it appears to be. The only difficulty to overcome is to place the second finger correctly. [Ex. 19.]

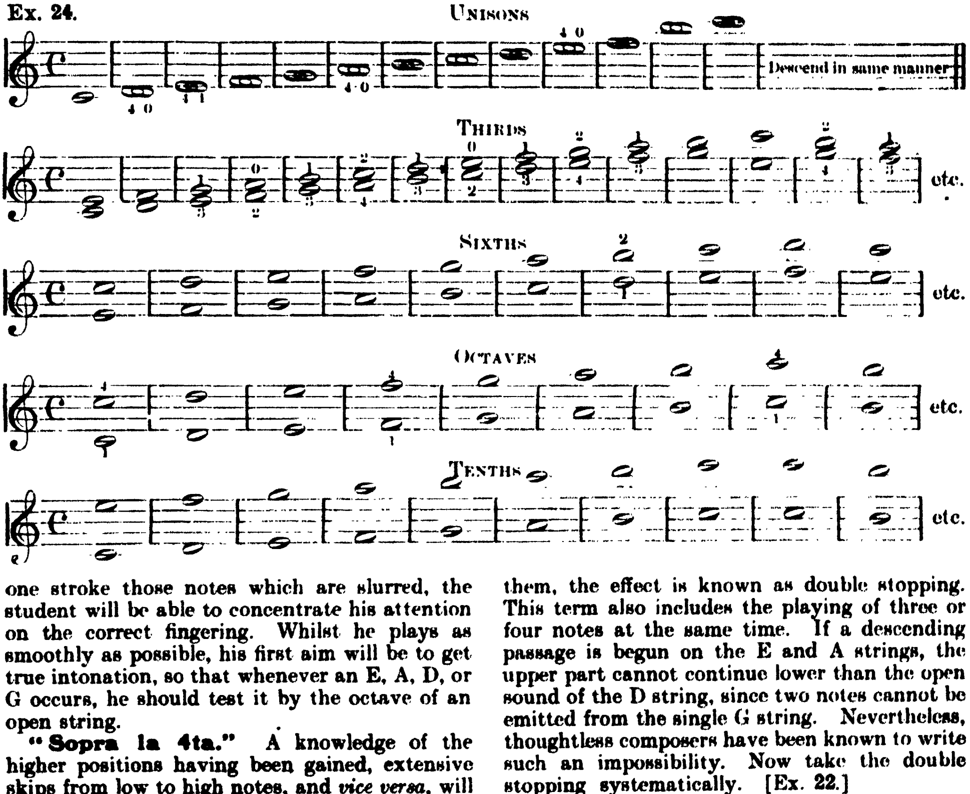
Whereas, in the second position, the low B is stopped by the first finger, and in the first position by the second finger, the hand being shifted nearer the nut, the same B is negotiated by the third finger. So the second finger takes the A two semitones above the open note of the G on the fourth string, the E two semitones above the open D of the third string, the B on the A string, and the G♭ or F♯ two semitones above the open E of the first string.

Interchanging Positions. Having learnt to play in each position as well as the half shift without moving the hand from its respective situation, the student should study to apply the knowledge he has acquired by transferring his fingers from one position to another, so that, no matter on what part of the fingerboard a scale or passage may lie, he may be able to execute the whole of a phrase in the most telling manner, with the least possible temporary hand movement [Ex. 19A]. If in the same group a fresh position has to be taken, and the finger, without leaving the string, glides from one interval to another, the art is so to make the movement as not to develop an ugly whine or wail. The matter of taking the different intervals is termed *portamento.*

Portamento. Even as, in singing, this implies a "lifting" of the voice from one note to another, and the "bearing and behaviour" meanwhile of the artist, so must the left hand of the violinist be taught by practice to move—in more senses than one—in a "correct" way, so that there may be no undue slipping about of the hand on the neck. This is not only ineffective, but undignified. The object in changing from one position to another is not to whine up and down the strings, but to finger with ease passages which otherwise might be difficult or impossible in the normal position. To enable the portamento to be done effectively, the left hand should be occupied solely in stopping the notes. The instrument, therefore, at such times will be held with extra firmness between the chin and collarbone. [Ex. 20.]

Extensions. In accordance with the way the fingers are stretched to stop the notes, so is the extension known as "superior" or "inferior." The tendency is to play hopelessly wrong notes when first essaying various changes of position. This should be carefully checked by the student transposing a high passage an octave lower. After playing it in the first position, so as to get the sounds well into his head, he can then try it in the higher shifts, together with the portamento effect desired. By continuing to use a uniform style of bowing, linking together with one stroke those notes which are slurred, the student will be able to concentrate his attention on the correct fingering. Whilst he plays as smoothly as possible, his first aim will be to get true intonation, so that whenever an E, A, D, or G occurs, he should test it by the octave of an open string.

Ex. 24.



"Sopra la 4ta." A knowledge of the higher positions having been gained, extensive skips from low to high notes, and *vice versa*, will become easy if carefully practised, the student always avoiding that whining effect which too much gliding gives. On account of the special character of tone which the lowest string possesses, several bars will sometimes be found marked "sopra la 4ta," which, in English, reads "upon the fourth" string. In that case, the whole of the passage, no matter how high it goes, must be played on the G, and the knowledge the student has of the higher positions will enable him to do justice to the [illegible] of the composer.

Four-string Chords. So far, we have confined our attention to the fingering of single notes. Agreeably with the human voice, but unlike the piano or organ, the violin is an instrument naturally adapted for monodic performance. Yet it excels the voice in that it can produce several sounds simultaneously from its four strings, certain of the notes being further apart than could be stretched with one hand by any pianist. Four-string chords are usually only possible with short notes. Whisk the hair quickly from the two lower to the two upper strings. Although the bow leaves the two lower strings, the vibrations of the latter continue, and so form the chord. Try Exercise 21 by drawing the bow with a semicircular motion firmly at the nut across all the four strings.

Double Stopping. When two strings are bowed together with either finger pressing them, the effect is known as double stopping. This term also includes the playing of three or four notes at the same time. If a descending passage is begun on the E and A strings, the upper part cannot continue lower than the open sound of the D string, since two notes cannot be emitted from the single G string. Nevertheless, thoughtless composers have been known to write such an impossibility. Now take the double stopping systematically. [Ex. 22.]

After combining the open string simultaneously with groups of four notes, try Exercise 23.

Get well under control ascending and descending unisons, thirds, sixths, octaves, and tenths. [Ex. 24.]

By changing the order and duration of these double notes, an inexhaustible series of studies can be made. The life of no violinist has yet sufficed for him to learn everything that can be acquired from this marvellous instrument.

ELECTRICITY

17

Continued from page 2218

ARC LAMPS

The Electric Arc. Distribution of Light. Inverted, Enclosed, and Alternating Current Arcs. Arc Lamp Mechanisms

By Professor SILVANUS P. THOMPSON

ONE of the first fruits of Volta's invention of the pile for generating continuous currents, in 1800, was Davy's discovery of the arc. He experimented on the spark that is produced between the ends of two wires through which the current from a pile, or battery of cells, is flowing when the wires are suddenly parted from one another, and observed that the spark produced between two pieces of boxwood charcoal is brighter than that between the tips of two metallic wires. Using more powerful batteries, he found that if the tips of the two pieces of charcoal are not withdrawn too far apart the spark becomes a persistent flame. In his experiments the two pieces of charcoal were held horizontally, and the flame so produced formed an arch between them, being drawn upward by the ascending air. This electric flame he called *the arc*. If produced thus with wood charcoal, the material disintegrates into the flame, which becomes itself extremely brilliant, though unsteady. Using a battery of several hundred cells, he was able to draw out the arc to the length of several inches **[170]**.

Forty years later, Foucault substituted for wood charcoal pencils of hard graphitic carbon of the kind which is found encrusting gas retorts, and which is used in making carbon plates for batteries. If this substance be ground up to powder, purified, mixed with a small quantity of tar to bind it together, compressed by hydraulic pressure into rods, and baked in closed crucibles at a bright red heat, the resulting pencils are hard and graphitic, and conduct well. A rod 0·5 in. in diameter has a resistance of about $\frac{1}{10}$ ohm per foot. Such pencils, of different sizes according to the current to be carried, are used in arc lamps.

Arcs of Various Kinds. In modern arc lamps the carbons are seldom disposed horizontally, as in Davy's arc, though this arrangement is still used in some forms of searchlights at sea. The several arrangements in general use are:

Vertical arcs.
Inverted arcs.
Enclosed arcs.
Alternate-current arcs.
Flame arcs.

By far the most usual of these is the vertical arc supplied with a continuous current. The carbons stand vertically over one another, separated by about $\frac{1}{8}$ in., and the current flows downwards, the positive carbon being above and the negative carbon below. It will be convenient to state the properties of this kind of arc first before discussing the other forms.

Properties of the Arc. Suppose a carbon rod 0·7 in. in diameter to be held vertically in a convenient holder so that it can be moved up and down and clamped at any point. Below it let there be placed in a line with it another slightly thinner carbon rod, say 0·475 in. in diameter. Let the upper one be joined to the positive main, and the lower one to the negative main. The voltage of these mains should be not less than 60 nor more than 100 volts, and a set of adjustable resistance wires should be inserted in the circuit to regulate the amount of current. Suppose, now, the tips of the two carbons be made slowly to approach toward one another, it will be found that nothing happens unless they are actually brought into contact. Even when the air gap between them is no thicker than a visiting card, the arc will not start of itself. To *strike* the arc, the carbons must be brought for an instant into actual contact, and then drawn back till they are separated by about $\frac{1}{8}$ in. At once the light flashes out as the arc forms itself, resembling the picture in **171**.

On examining the arc through dark glasses—to prevent injury to the eyes—or by projecting an image of it on the wall with a lens, several points will be noticed. The flame itself gives almost no light, and consists of an inner core of pale violet colour, surrounded by an outer envelope of a greener tint. A dazzling white light is given out from the bottom end of the upper carbon, and a less amount from the top end of the lower carbon. In fact, the source of the light is the surfaces of the white-hot tips of the carbon rods. These gradually burn away and assume the shapes shown in the figure. The positive carbon assumes the form of a cone truncated at the bottom. The conical part glows red-hot, but the bottom surface, which is hollowed to a sort of *crater*, glows white-hot. The negative carbon is also coned, and acquires a projecting peak, the tip of which is white-hot. Nearly all the light comes from the positive *crater*, and therefore the main light of the arc is thrown downwards. The temperature of the crater is about 3500° C., that of the negative peak about 2700° C.

Instability of the Arc. The arc, being a flame, is liable to be blown aside by currents of air, hence it must be protected by a glass globe. It can also be deflected on one side by a magnet, since it is a flexible conductor of the current. If the upper carbon be slowly drawn upward the arc lengthens and becomes unsteady. If the length from tip to tip exceeds about $\frac{1}{2}$ in. the arc goes out, and does not relight itself unless the tips are again brought into momentary contact to re-strike the arc.

179. DIAGRAM OF CONTROL OF ARC BY SHUNT E.M.

DIAGRAMS ILLUSTRATING PRINCIPLES AND MECHANISMS OF ARC LAMPS

If higher voltages are used, the arc can be drawn out longer, but in this there is little advantage. If the carbons are brought too near together, without touching, the arc hisses and becomes unsteady, while an excrescence of carbon, called a mushroom, forms on the negative peak. The hissing is due to air getting to the crater surface. A steady arc cannot be formed unless the electromotive force exceeds 40 volts or so.

Feeding the Arc. If the carbons are held fixed in a constant position they gradually consume away by combustion, the positive one consuming about twice as fast as the negative one. Hence the arc itself gradually lengthens and becomes unstable, and will go out unless means are taken to move the carbons nearer together and so bring back the arc to its proper length. In arc lamps a mechanism is provided to move the carbons little by little nearer together as they burn away—in other words, to *feed* the carbons forward into the arc. When the top carbons used are twice the section of the bottom ones, each will burn away at a rate of about two-thirds of an inch in the hour. To make the arc more steady the top carbons are often made with a central hole filled from top to bottom with a *core* of softer carbon.

Distribution of Light from the Arc. The size of the crater that emits the light is nearly proportional to the number of amperes flowing through the arc. With a 10-ampere current the crater has about $\frac{1}{20}$ of a square inch of surface, and therefore a diameter of about 0·16 in. A circle of white-hot carbon of this size would emit in the direction normal to its surface a light about equal to 2,000 candles. But in oblique directions the light would be less in proportion to the cosines of the angles; and moreover in the actual case the negative carbon gets in the way and casts a shadow downwards. Hence the light is greatest in an oblique direction and from an arc of this size is less than 2,000 candles in the maximum direction, and is indeed less than 800 candles if the average value in all directions is reckoned. If the negative carbon did not get in the way the light from a crater of this size would have the following values at the several angles, reckoned below horizontal:

Angle	0°	15°	30°	45°	60°	75°	90°
Light	0	520	1000	1414	1730	1930	2000

These amounts are exhibited graphically in 172. But as the negative carbon eclipses a lot of the light, and as its tip throws a little light out sideways, the actual distribution would be more nearly represented by the values:

Angle	0°	15°	30°	45°	60°	75°	90°
Light	220	700	1250	1420	720	0	0

These values are given graphically in 173. The amount cut off by the negative carbon would be greater if the arc had been shorter. The circle of shadow cast by the negative carbon can be observed on the opal globes of ordinary arc lamps.

Inverted Arcs. For lighting picture galleries, drawing offices, and workshops, it is often preferred that the light should be thrown upwards on to a whitewashed ceiling rather than downwards; inverted arcs are then used, with a thick positive carbon at the bottom and a thinner negative one at the top. The advantage is that with the light thus diffusely reflected from the whitened surfaces no shadows are cast.

Enclosed Arcs. To reduce the consumption of carbon, which results from the access of the air, and to lessen the cost of maintenance and attention, it has become the fashion to surround the arc by a globe entirely closed at the bottom and nearly closed at the upper part. When the lamp is first lighted the oxygen present in the air of the globe is quickly consumed, and after that there is left in the globe only an inert atmosphere, in which the carbons will last six or seven times longer than they would in an open globe. The enclosing vessel must not be absolutely air-tight, or it will blacken. In the enclosed arc the carbons assume a different shape, with neither crater nor peak, but nearly flat at the ends [174]. To get a good distribution of light the arc must be drawn out longer, and as the greater length of the gaseous column will offer a greater resistance, higher voltages—from 70 to 80 volts across the arc—are employed. Some enclosed lamps have double globes, a small inner globe and a larger outer. This is, however, unnecessary.

Alternate Current Arcs. When an alternating current is used, each of the tips emits light; for since the current flows first up, then down, in rapid alternation, each of the tips becomes alternately positive, and each acquires a small crater. As a result, the light is thrown partly obliquely upward and partly obliquely downward, the distribution being as indicated in 175. It is, therefore, usual to surround the upper carbon a little above its tip with a reflector to throw downwards the upper part of the light. The alternating arc can be worked with a voltage of from 33 to 45 volts. If enclosed, to make the consumption of carbon slower the voltage can be increased.

Arc Lamps. Hitherto we have spoken of the electric arc pure and simple; we now come to see how it is arranged for practical lighting purposes. The mechanism which makes the burning of the arc automatic when once the current has been switched on must perform the following functions: (1) bring the carbons together when no current is flowing; (2) strike the arc—*i.e.*, move the carbons a suitable distance apart—when the current is switched on; and (3) feed forward the carbons as they burn away, so that a constant length of arc is maintained. Various other things are required in special cases, but the above are fundamental. We may deal with them in order. (1) When the current discontinues to flow, the usual action is that all regulating mechanism becomes inert, loses any grip of the carbons which has been necessary to regulate them, and the top carbon by virtue of its own weight drops into contact with the bottom carbon. (2) Many mechanical contrivances have been invented for striking the arc, but the two most important are the clutch and the brake-wheel mechanism. In present-day lamps the same mechanism is arranged to do both the striking and the feeding, therefore these two operations may be considered together.

Mechanical Part of the Arc Lamp Mechanism. For our present purpose it will suffice to give typical examples illustrating the main forms which are in use, and finally to describe one lamp in detail, so that the reader may be able to combine any of the parts separately described into a completed form.

Brake-wheel Mechanism. The weight of the descending upper carbon and its holder drives a wheel, against the rim of which a brake can be applied. This brake is operated by a lever that is automatically raised when the current is strong, and lowered when the current is weak. Suppose the carbons to be resting one against the end of the other. Then when the current is switched on, as the resistance is small, there will be a strong current which causes the lever to rise, gripping the brake against the wheel and turning or raising it, and so lifting the upper carbon and striking the arc. After a few minutes, when the tips have burned away a little, the arc offers more resistance, and the current therefore decreases. Hence the regulating lever falls, and by releasing the wheel permits the top carbon to descend a little, when the increase of current again checks the movement. Fig. 176 shows a brake-wheel mechanism.

Clutch Mechanism. The clutch may be arranged to act either directly upon the upper carbon rod, or upon a metal rod that holds the upper carbon. The action is similar to that of the brake-wheel, the clutch nipping against the carbon rod and raising it a little when the regulating lever is raised, and releasing the carbon rod when the regulating lever falls. The action will be evident from inspection of 177.

Electrical Part of Controlling Mechanism. Arc lamps are run on the series, parallel, and series-parallel systems of supply [see page 2245]. The problem in the design of a mechanism is to arrange that the energy given to each lamp is the same, so that equal amounts of light are emitted. Obviously, in the series system, as the *same* current must flow through each lamp, we must arrange that the voltage is equally distributed; in the parallel system it is the current in each lamp which has to be regulated, for the voltage is constant; and in the series-parallel arrangement, where, say, sets of three lamps are run off 250-volt mains, we have to see both that each set takes the proper current, and that the voltage is divided equally among the three lamps. These various arrangements are made by varying the windings on the coils. If we wish to regulate the current we send the actual current which passes through the arc round a coil of thick wire [178], and when the current is of the right strength we arrange that the arc is opened to the requisite amount.

If it be the voltage that must be regulated, we use a coil of thin wire and connect it across the arc, and when the arc has the correct voltage, the current which flows around this *shunt* coil [179] is just sufficient to maintain the carbons the proper distance apart.

If we wish to regulate both voltage and current two coils are used. These may, of course, be wound upon the same core, but as it is desirable to have some weight (or some *inertia*) in the mechanism, the arrangement shown in 180 is often adopted, wherein a see-saw lever carrying an iron plunger at each end is acted upon by two coils, one of thick wire in series with the arc, the other of fine wire placed in shunt.

Example of an Arc Lamp. The example given in 181 is a very simple and effective construction due to Messrs. Johnson & Phillips. A coil in the upper part of the lamp (shown in section) draws up magnetically an iron plunger of conical form, and with it raises a series of L-shaped nipping-levers which grip the upper carbon rod and raise it. The pattern shown is that used with an enclosed arc, there being a small enclosing globe, into which the upper carbon enters, as well as a larger surrounding lantern or outer globe.

GROSS PROFIT

Accounts and Nominal Accounts. Prime Costing. The Quantitative Method. Testing the Results of Stocktaking. Checking Fraud

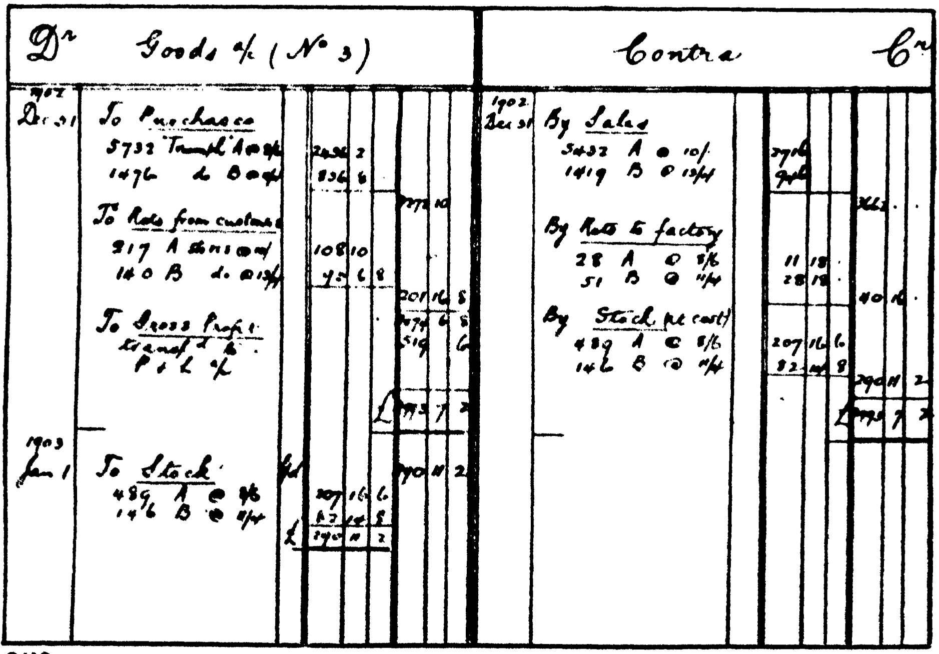
By A. J. WINDUS

THE most troublesome item in the goods account is that relating to stock. The reason exists in the dual nature of the account itself.

Accounts and Nominal Accounts. In the first place it belongs to the class of *real* accounts, which also embraces cash, bills payable, bills receivable, fixtures and fittings, and every species of property employed in or associated with an undertaking. But upon reflection we must admit that the goods account also belongs, in part at least, to the class of *nominal* or temporary accounts. Such accounts exist in name only. They are, in fact, sub-accounts, which for the sake of convenience are kept separate until merged by transfer in some account of superior degree. To this class belong the sub-accounts which jointly constitute the profit and loss account, as rent, rates and taxes, salaries and wages, trade expenses, discounts, and all sub-accounts of gains, losses, and expenses.

The goods account is related to this group through the sales. Every profitable sale is effected at a price which represents cost *plus* profit. The theory is that these accumulated profits are periodically transferred to profit and loss account. The adjustment by transfer having been made, it is possible by deducting the total credit on goods account from the total debit to arrive at the cost of the unsold goods or stock on hand. Whatever its amount, it would first be placed on the credit side of goods account to make it balance, and would then be brought down on the opposite, or debit, side as the first item in the new account, the old account being ruled off in the ordinary way.

Stock in Hand. In practice, however, the value of the stock on hand is ascertained by actual survey of the unsold goods, in the same way as the amount of cash on hand is found by counting the cash in the till. But while there should be an exact correspondence between the amount of cash in the till and the cash balance disclosed by the office cash account, there is ordinarily no such correspondence between the amount of goods on hand and the balance of goods account in the ledger. Theoretically, there is no reason why after allowing for profit or loss on goods sold, and perhaps for reduced value of goods unsold, the balance shown on the goods account should not coincide with the value of the stock on hand as ascertained by survey—*i.e.*, stocktaking. We may illustrate this by an example. At the end of the first year's trading, Mr. Andrew Crawford learned as the result of stocktaking that he had on hand 489 size A and



Dr Goods a/c (No 3)

						40	16	.
	By Stock (at cost)							
	489 A @ 8/6		207	16	6			
	146 B @ 11/4		82	14	8			
						290	11	2
						£3993	7	2

[illegible] stoves. These be valued at cost, and on this basis the stock was worth £290 11s. 2d., viz:

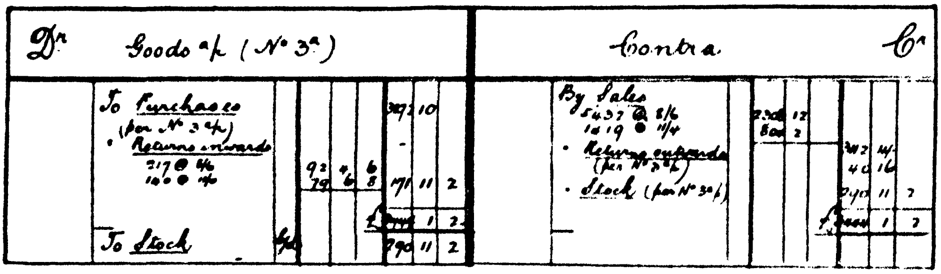
	£	s.	d
489 A stoves @ 8s. 6d. =	207	16	6
146 B stoves @ 11s. 4d. =	82	14	8
Total	290	11	2

The total agrees with the balance brought down on goods account No. 1 and on goods account No. 2, after the accumulated profits on sales have been transferred to P. and L. account. But those accounts are not sufficient in themselves to explain the coincidence. Attention is therefore directed to goods account No. 3 [see preceding page], wherein the facts already dealt with in the two preceding accounts are treated quantitatively.

By a slight rearrangement of the figures we are able to confirm the stocktaking quantities as follows:

A.			B.
5732	No. of Stoves purchased		1476
28	Less returned to factory		51
	5704	Net purchases	1425
5432	No. of stoves sold		1419
217	Less returned by customers		140
	5215	Net Sales	1279
489	No. of stoves in stock, 31 Dec., 1902		146

Gross Profit. The selling prices of A and B stoves are 10s. and 13s. 4d. as compared with cost prices 8s. 6d. and 11s. 4d. respectively. Hence arises the gross profit of £519 0s. 6d. It follows that if cost and selling prices were identical the item "gross profit" would disappear from the goods account altogether, although the balance representing stock on hand brought down would remain unaltered. Thus, if in goods account No. 3 the cost prices were adopted for the whole of the calculations on both sides of the account we should obtain this result:



Dr	Goods a/c (No 3a)					Contra				Cr
	To Purchases (per No 3 a/c)			[illegible]	10		By Sales 5432 @ 8/6 1419 @ 11/4	2308 12 804 2		
	" Returns inwards 217 @ 8/6 140 @ 11/4	92 4 6 79 6 8		171	11 2		" Returns outwards (per No 3a/c)		[illegible] [illegible] 40 16	
							" Stock (per No 3a/c)		290 11 2	
				£[illegible]	1 2				£[illegible] 1 2	
	To Stock			290	11 2					

Several important facts emerge from a comparison of account No. 3 with account No. 3a. First we notice that in spite of the evanishment of gross profit from the latter the amount of stock on hand at end of 1902 has undergone no change. This constancy emphasises the fact that the value of the unsold goods at stocktaking is not necessarily the difference between the two sides of the goods account, although it happens to be so in account No. 3a. Stocktaking, indeed, proceeds quite independently of the goods account in the ledger. Nevertheless, the results of stocktaking must be known and incorporated in the goods account ere we can decide the question as to whether a trading profit has been made.

Therefore, the first step towards closing the goods account is to take stock. The second step is to credit by the value of the stock on hand the account about to be closed, at the same time opening a new account and debiting it with the value of the stock transferred thereto. If, as in example No. 3a, the two sides of the old account then agree, we are forced to the conclusion that no profit has been made. If, as in the three preceding accounts the total of the credits exceeds the total of the debits, the difference or margin is gross profit. To dispose of this difference a transfer entry should be put through the journal and posted, debiting goods account and crediting profit and loss account [see rule for transfers, page 1569].

In a goods account constructed on the lines of example No. 3 before us, we are able to utilise the recorded quantities and prices in verifying the accuracy of the gross profit as stated. We have seen that profits are derived solely from the sales, but that they are liable to diminution by the amount of any shrinkage in value of the unsold goods. In the present case there is no shrinkage, and the calculation to be performed becomes a simple matter. Allowing for returns from customers, 5,215 A stoves were sold at 10s. each, being an advance over cost of 1s. 6d. per stove; therefore, the total profit on A stoves must be 1s. 6d. × 5,215 = £391 2s. 6d. Again, 1,279 B stoves were sold at 13s. 4d. each, or an advance over cost of 2s. per stove. The total profit on B stoves is, therefore, 2s. × 1,279 = £127 18s. 0d. If this amount be added to the profit of £391 2s. 6d. on A stoves, we shall obtain a combined profit of £519 0s. 6d., as shown.

The Quantitative Method. Quantitative accounts of raw material, labour, finished products, and expenses of production are essential to every genuine system of cost accounts. Prime costing, as it is termed, is a latter-day development of accountancy, but more especially of the analytic method to which reference has been made. It is resorted to chiefly by the contractor and the manufacturer; by the contractor because estimates for work proposed to be undertaken should be founded upon data supplied by the prime cost accounts of executed contracts;

by the manufacturer because thereby an efficient control over every department of manufacturing can be maintained.

Outside these two classes of business men, the quantitative method of account-keeping meets with small favour, and the reason is not far to seek. It is a good business maxim that the result aimed at should be commensurate with the effort put forth, and it is generally felt that the labour of keeping continuous and classified records of the quantities of stock bought and sold from day to day is too high a price to pay for the consequent benefit of being able to check the quantities of stock on hand as ascertained by actual survey with the balances appearing in the stock register.

Testing Stocktaking Results. Accordingly, business men have adopted a shorter method of testing the results of stocktaking which, although not absolute, answers all practical purposes. The method referred to consists in ascertaining whether the *rate* of gross profit earned is a proper one, having regard to all the circumstances. If the rate is normal, or varies but slightly from the normal, and the prices, extensions, and summations of the stock book have been carefully verified, then the amount of stock on hand is assumed to be correctly stated; but if the rate is abnormal an investigation of the goods account, including the item of stock on hand at the end of the period, will have to be made.

For instance, in goods account No. 2, quantities are not registered, but values only. Taking the net sales as £3,460 3s. 4d. (£3,662—£201 16s. 8d.), the gross profit as £519 0s. 6d., and applying the rule for percentages, the profit works out at a rate of 15 per cent. on the sales (£519·025 × 100 ÷ £3,460·16 = 15). Mr. Crawford is satisfied from this showing that the value of the stock is correctly stated, because his selling prices were calculated on a basis of 15 per cent. "on returns."

Thus, if 1s. 6d., which is 15 per cent. on 10s., be deducted from the selling price of A stoves, we shall arrive at the cost price, 8s. 6d.; so also, if 2s., or 15 per cent. on 13s. 4d., be deducted from the selling price of B stoves, the cost price, 11s. 4d. will stand revealed.

In a great many businesses, the stock comprises a variety of articles of trade, and the prices are legion. Here, it would be folly attempting to prove the value of the stock by making calculations based upon the difference between cost and selling prices. The simplest plan is to adopt an *ideal* rate of gross profit for each business coming under this category, and to treat any marked deviation therefrom in the *actual rate* as a warning not to pass the item of stock in the goods a/c without further inquiry.

To determine the ideal profit rate which should obtain in a given case, it is advisable to fall back upon the experience of former years, or of other people engaged in the same trade. While it is true of trade generally that different rates of gross profit prevail where trades are dissimilar, it is, with certain reservations, no less true that in any particular trade there exists a recognised standard of gross profit to which the majority of the traders endeavour to conform. Industrial competition—that great leveller of prices—is mainly responsible for this tendency of gross profit rates to become uniform; but we merely note the fact and pass on to illustrate the mode of applying the ideal or standard rate of gross profit in the detection of error.

Suppose that the goods account in Mr. Crawford's ledger had been kept in abstract form as shown in goods account No. 2, but that while the figures for purchases, sales and returns were the same as given in our example, the amount of "stock on hand (at cost)" differed, being recorded as £248 1s. 2d. instead of £290 11s. 2d. We should expect to find this reduction in the ledger value of the stock reflected in the decrease of gross profit shown, and this is precisely what happens [see account below].

Taking the *net* sales as £3,460 3s. 4d. and the gross profit at £476 10s. 6d., Mr. Crawford would have discovered that the rate of profit worked out at slightly under 13·8 per cent. This result being clearly inconsistent with the fact of a 15 per cent. margin of profit between cost and selling prices he would feel convinced that something was wrong. In the case we are supposing, a careful recount of the stoves in stock revealed the fact that a mistake had

Dr	Goods a/c (No. 2)						Contra				Cr

	" Do (returns inwards)		201	16	8		" Do (returns outwards)		40	16	
	" Balance, being Gross Profit c/d to Profit & Loss a/c		476	10	6		" Stock on hand (at cost)	c/d	248	1	2
			£3950	17	2				£3950	17	2
1903 Jan 1	To Stock	b/d	248	1	2						

been made in counting 389 A stoves instead of 489. The error produced a depression of £42 10s. 0d.—representing the cost of 100 A stoves at 8s. 6d. each—in the *book value* of the stock. When the necessary adjustment had been made, the amount of stock would appear as £290 11s. 2d., the gross profit would be correspondingly increased to £519 0s. 6d., and the rate of profit would work out at 15 per cent. as required.

If, when tried by the touchstone of the standard rate of gross profit, an actual rate appear erroneous, we may be sure that, whatever the source of the discrepancy, it is of sufficient importance to warrant an attempt to locate it. Sometimes a discrepancy can be shown to be the result of legitimate causes, and at other times the most determined efforts to unravel the mystery may prove unavailing.

Frequently, however, the knowledge that the actual rate of gross profit is false has led to the discovery of the fraud or error which it prognosticates.

Falsification of Profit. For the trained auditor the subject of Fraud or Wilful Error in its manifold aspects as relating to accounts possesses a peculiar interest. We will select three examples of the falsification of profit.

1. The managing director of a limited liability company holds certain shares in the company which he desires to sell at the best price obtainable. It is, therefore, to his interest that the market value of the shares should rise; and a powerful lever for forcing the price of shares upwards is the payment of satisfactory dividends to the shareholders. By law, however, dividends must be paid out of profits only, and, other things being equal, the sum available for dividend distribution among the shareholders will vary directly with the amount of *net* profit, and this in turn will be profoundly affected by the amount of gross profit made. In order to inflate the amount of gross profit, the managing director caused certain invoices for goods arriving immediately prior to stocktaking to be "dated forward"—*i.e.*, post-dated—and omitted such invoices from the debit side of goods account, despite the fact that the goods to which they referred were included with the rest of the unsold goods in the item "stock on hand" on the opposite side of the goods account. Consequently, the gross profit balance shown on goods account was largely fictitious; but everything seemed to be quite in order, the stock book having been examined, and the usual inquiry as to whether all invoices had been passed through having been answered in the affirmative. So it is at least doubtful whether, failing the application of the gross profit percentage test, the deception would have been laid bare in time to prevent the payment of a dividend which had not been earned.

2. A boot and shoe dealer wishing to conceal from the Income Tax authorities a portion of his trading profits took stock, and in the process marked down the cost prices of all unsold goods by 25 per cent. Thus stock on hand was credited in the goods or trading account at a reduced amount, the gross profit balance transferred to profit and loss account was lessened thereby, and the final balance of net profit transferred from profit and loss account to capital account was likewise diminished.

Under certain conditions such a reduction would be fully justified. Thus, if the cost prices at the time of stocktaking had actually sunk to the level here indicated, then the unsold goods, even though they had cost more, would not be *worth* more to the business than new goods of the same description—especially in view of the fact that when wholesale prices are declining retail prices display a sympathetic downward tendency. Accordingly, the unsold goods should not be valued at more than the totaal mount for which they could, if necessary, be replaced immediately upon the conclusion of stocktaking.

It may occur to some that if, as compared with the actual purchase prices, the market prices at stocktaking of unsold goods had *risen* the trader would have been entitled to value his stock at the higher level of prices, but this idea is fallacious. The trader who schedules his unsold goods at higher prices than he paid for them is simply "anticipating profits"—a dangerous policy, because until goods have been sold no profit has been earned. To show a fictitious gross profit in the goods or trading account by overstating the value of the stock is to court disaster. Hence the excellent rule that goods are to be priced out in the stock book at cost or market price, *whichever is lower*.

The fraud committed by the boot and shoe dealer in the case before us consisted in depressing the value of his stock below cost at a time when, owing to the advance in the price of leather, and the consequent rise in wholesale prices, his unsold goods had become more valuable than when he bought them. Stock which was worth at cost, say, £1,000 was brought into the goods account at £1,200, and the net profit, which in reality was £500, appeared in the profit and loss account as £100 only.

3. A firm of merchants were in the habit of taking press copies in a tissue copy book of all invoices despatched. These copy invoices were not posted direct to the sales ledger, but were entered in abstract form in a sales journal, and from thence the amounts were posted to the respective sales ledger accounts. The bookkeeper, who was also the cashier, hit upon the expedient of omitting to pass certain invoices through the sales journal, and consequently they did not appear in the sales ledger. In due course the amounts of these omitted invoices were received from the debtors and came to the hands of the cashier, who retained them for his own use. Since he was careful not to record these amounts in the cash book, there was no discrepancy between the cash receipts and the bank lodgments, which might have aroused suspicion, and in the result the profits of the year during which these practices prevailed showed a serious falling off.

NEW STREETS & FOTPATHS

Requirements and Cost. Dedication as Public Highways. Setting out Footpaths. Costs of Construction and Maintenance

By A. TAYLOR ALLEN

A *street* defined by the Public Health Act, 1875, and the Private Street Works Act, 1892, is a highway, bridge (not being a county bridge), road, lane, footway, square, court, alley, or passage, whether a thoroughfare or not.

Highways under the Highway Act, 1835, mean all roads, carriageways, cartways, horseways, bridleways, footways, causeways, churchways, and pavements.

Requirements of Local Authorities. Section 150 of the Public Health Act, 1875, enacts that where any street within any urban district (not being a highway repairable by the inhabitants at large), or the carriageway, footway, or any other part of such street is not sewered, levelled, paved, metalled, flagged, channelled, and made good, or is not lighted to the satisfaction of the urban authority, such authority may, by notice addressed to the respective owners or occupiers of the premises fronting, adjoining, or abutting on such parts thereof as may require to be sewered, levelled, paved, metalled, flagged, or channelled, or be lighted, require them to sewer, level, pave, metal, flag, channel, or make good, or to provide such proper means for lighting the same within a time to be specified in such notice.

If such notice be not complied with, the urban authority may, if they think fit, execute the works mentioned or referred to therein, and may recover in a summary manner the expenses incurred by them in so doing from the owners in default, according to the frontage of their respective premises, and in such proportion as is settled by the engineer of the urban authority.

Powers of Urban Authorities. An urban authority may adopt the Private Street Works Act, 1892, in place of sections 150, 151, and 152, of the Act of 1875. Under this Act, questions between the owners and the authority as to whether the street is one which can be made up at the owner's expense, as to informality in the notices, etc., as to the sufficiency or reasonableness of the works, and as to the apportionment of the expenses, are to be determined before the works are actually executed.

This more recent enactment is that under which most of the private streets are now made up.

The period usually allowed by the Local Government Board for the repayment of Loans for Private Streets Works is from four to six years.

Plans, Sections, and Estimates. Before a local authority gives the owners notice to make up a street, their engineer must prepare plans and sections, which should be on a scale of not less than 1 in. for 88 ft. for a horizontal plan, and on a scale of not less than 1 in. for 10 ft. for a vertical section, such plans, with the estimate, being deposited in the council's offices, and open at all reasonable hours while the notices run, for the inspection of all persons interested therein.

Before the preparation of such plans and sections, it will be necessary for the engineer to make an accurate survey of the street or streets to be made up.

Each frontage is measured and entered in a book, these dimensions acting as a check to the plotting of the various points taken from the offsets off the chain line.

Plans should be neatly and clearly drawn; if the plans are on loose sheets, there should be a title and scale on each sheet, and the date, with the name of the engineer clearly written in the right-hand corner.

Details, such as manholes, type of gully, paving, etc., should be drawn to a large scale, with figured dimensions.

The Preliminary Survey. The plans and detailed section can be prepared only after an accurate survey of the streets. The section should show a horizontal "datum line," and lines showing the "formation level," and "finished surface" of the proposed works. Figures should also be given on the datum line for the horizontal distances, corresponding exactly with those on the plan, and the heights of the surface of the ground above datum require to be marked at intervals, as well as the depths of the sewers with their cross-sectional dimensions and gradients distinctly marked upon them.

A detailed estimate, showing particulars of the probable cost of the whole works, including a commission of 5 per cent. (which is allowed under Sec. 9) in respect of surveys, superintendence, and notices, should be prepared and must include provision for sewering, levelling, paving, metalling, channelling, kerbing, making good, and providing proper means of lighting.

Each street to be made up must be kept entirely distinct. Fig. 13 illustrates the laying out and making up of a new street; Fig. 14 is the plan of a private street showing apportionments.

Apportioning Cost Among Owners. Under the Public Health Act, 1875, the principle adopted in making the apportionment is based on frontage only, but the Private Streets Works Act, 1892, gives the local authority power to decide whether the apportionment is to be made according to the frontage only or to take into account the degree of benefit derived by any premises having access from the street, and the amount of work already done by any of the owners. Therefore, before the engineer proceeds

13. DIAGRAMMATIC REPRESENTATION OF THE LAYING OUT OF A NEW STREET

to prepare the provisional apportionment, he must be clear on these points.

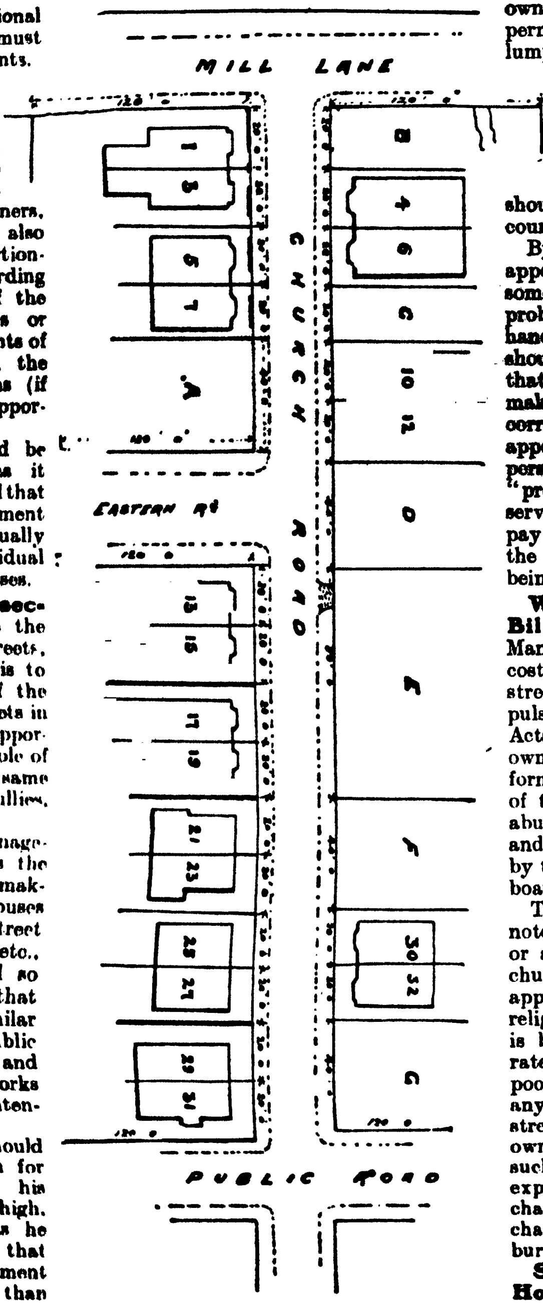
The provisional apportionment should show the amounts charged on the respective premises, the names of the respective owners, or reputed owners, also whether the apportionment is made according to the frontage of the respective premises or not, the measurements of the frontages, and the other considerations (if any) on which the apportionment is based.

This work should be accurately done, as it must be remembered that the exact measurement of a frontage is usually known to the individual who owns the premises.

Street Intersections. As regards the intersections of streets, the usual practice is to include the cost of the intersections of streets in the amount to be apportioned over the whole of the frontages in the same way as manholes, gullies, and lamps.

The Metropolis Management Act, 1862, is the *only Act expressly making the owners of houses and land in the street liable for the paving, etc., of intersections, and so it may be presumed that* the omission of a similar provision in the Public Health Act, 1875, and Private Streets Works Act, 1892, was intentional.

The engineer should allow a fair margin for contingencies, and his estimate should be high, rather than low, as he must bear in mind that his final apportionment must not be more than 15 per cent. in excess of his estimate.



14. PLAN SHOWING APPORTIONMENTS UNDER PRIVATE STREET WORKS ACT, 1892

Final Apportionment. The preparation of the final apportionment is the last duty that the engineer usually has to perform, and he should exercise care that the charges in his apportionment are for the works described in the notices served upon the owners. It will not be permitted for him to lump the costs of a group of streets together, and apportion them amongst the owners of all. An apportionment, if requiring to be corrected, should be laid before his council again.

By the time the final apportionment is ready some property will most probably have changed hands, and the engineer should bear in mind that it is his duty to make the necessary correction on the final apportionment, as the person upon whom the "provisional" notice was served cannot be made to pay if he has ceased to own the property, the charge being on the properties.

Who Pays the Bill. By the Metropolis Management Acts, the costs of paving a new street under the compulsory powers of the Acts, are payable by the owners of the houses forming the street, and of the land bounding or abutting on such street, and are to be apportioned by the vestry or district board of works.

The engineer should note that the incumbent or any minister of any church, chapel, or place appropriated to public religious worship, which is by law exempt from rates for the relief of the poor is not liable to any expenses in private streets works, as the owner or occupier of such place, nor is any expense deemed to be a charge on such church, chapel, churchyard, or burial ground.

Street-Naming & House-Numbering. It was not until the commencement of the present century that inconvenience was apparently felt from the want of any distinguishing names of streets, or numbers to houses.

The Towns Improvement Clauses Act, passed in 1847, gave power to local authorities to cause names of streets to be marked or painted on a conspicuous part of some house, building, or place, and also power to compel occupiers of houses to mark their houses with approved numbers.

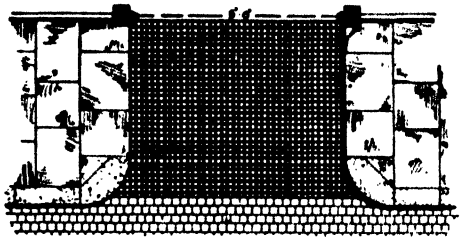
Names of streets should be marked up in such a way as to be legible both by day and night. The best description of street name-plates are white glazed china tiles, 6 in. square, on which either blue or black letters are burnt in, one letter on each tile. These are fixed by chasing them into walls of buildings and setting in cement.

The best method of house numbering is by allotting even numbers on one side of the street, and odd numbers on the other side.

Dedication as Public Highways. The parties proposing to dedicate a new road laid out in rural districts as a public highway, must give the engineer and surveyor of the local authority three months' notice in writing of such intention, and further construct the same in a substantial manner, and of the width required by the Act to the satisfaction of the surveyor and two justices who, on receiving such notice, shall view and certify the same, when, after being used by the public and kept in repair by the said party for a period of twelve months, such road shall become a dedicated highway repairable by the inhabitants at large.

Under the Public Health Act, 1875, the local authority may by notice in writing declare a street to be a highway repairable by the inhabitants at large, after the works specified by them have been executed, provided that no such street shall become a highway so repairable if within one month after such notice has been put up the majority of the owners of such streets object thereto.

Under the Private Streets Works Act, 1892, a local authority may take over a street in a similar manner whenever *all* or *any* of the works specified by them have been executed.



15. PLAN SHOWING PRIVATE CARRIAGE ENTRANCE ACROSS A PUBLIC FOOTPATH

Setting out Footpaths. The model bylaws made by the Local Government Board respecting new streets require that all footpaths of a street shall be of a width not less than one-sixth of the entire width of the street.

The following is an explanatory example of this requirement:

Entire width of street.		Width of path on *each* side.		Width of carriageway.	
Ft.	In.	Ft.	In.	Ft.	In.
60	0	10	0	40	0
50	0	8	4	33	4
42	0	7	0	28	0
40	0	6	8	26	8
36	0	6	0	24	0

The slope (cross fall) from back edge of path towards the kerb to fall at the rate of one-half of an inch in every foot of width, if the footpath be not paved, flagged, or asphalted, and at the rate of not less than a quarter, and not more than one-half of an inch in every foot of width if the footway be paved, flagged or asphalted.

In excavating to the required depth for paving the best method is to put wooden pegs so that the upper ends represent the finished surface, and then to excavate to the required depth below the top of the pegs.

In practice, paths are usually laid to the following table, which, it will be observed, complies with the above requirements.

Nature of Paving.	Cross fall, per foot of width.
Asphalt	[illegible] in.
Bricks	[illegible] "
Concrete	[illegible] "
Gravel	[illegible] "
Stone (artificial and natural) ..	[illegible] "
Tar	[illegible] "

The height of the kerb or outer edge of the footpath, except in case of crossings paved or otherwise formed for the use of foot passengers, shall be not less than 3 in. at the highest part of the channel, and not more than 7 in. at the lowest part of such channel.

The reason for this requirement of the Local Government Board is that a height of less than 3 in. would render it possible for vehicles to drive on to the footpath, or for the water in the channel to overflow it, and with a height of more than 7 in. it would be inconvenient for foot passengers. Where it is necessary to construct a carriageway entrance across a path, vitrified bricks or granite setts should be laid on concrete [15].

[See Kerbing and Channelling, page 2326, for examples in actual practice.]

Asphalt. Asphalt is largely employed as a paving material for footways. It makes an excellent footpath, being durable, non-slippery, expeditiously laid, pleasant to walk upon, and not glaring to the eyes.

Unfortunately, on account of what is technically termed *creeping*, it cannot be laid on paths having a considerable inclination, or cracks occur with increase.

Mastic asphalt is more commonly used upon footpaths than *compressed* asphalt. Asphalt, properly so called, is a natural compound of carbonate of lime and bitumen, and is found principally in volcanic areas, the proportion varying from 7 per cent. bitumen and 93 per cent. carbonate of lime to 20 per cent. bitumen and 80 per cent. carbonate of lime. Men of erudition have asserted that it was the pitch used to make the ark watertight, and that it was the slime used as a mortar in the construction of the Tower of Babel.

Manufacture of Mastic Asphalt. The process of manufacture into a mastic or semi-liquid state is as follows: the pieces of raw rock, weighing ¼ cwt. to ½ cwt. each, are placed in an asphalt crusher, where they are broken into small pieces. After passing through the crusher, the asphalt is carried up by elevators to the disintegrators, which run at a speed of 1,800 revolutions per minute, and is ground to a very fine powder.

This powder is then put into specially-made cauldrons, and gently boiled and worked by agitators with certain proportions of refined bitumen (added as a flux), and when heated to a temperature of about 400 F., a mixture of fine Bridport grit is added (in making mastic asphalt), and then roughly incorporated with the asphalt by the rotary working of the agitators. It is then turned out into iron moulds, forming the well-known cakes, which weigh about ½ cwt. each. These cakes are broken up into pieces on the site where the asphalt is to be laid, and placed into small portable cauldrons with just sufficient bitumen as flux, and, when properly heated, the asphalt mastic is ready to be spread over the cement concrete surface to the thickness required. It is then turned into iron moulds, forming the well known cakes, which weigh about 56 lb.

Asphalt Laying. These cakes are usually sent by the manufacturers to the site where the paving is to be laid, and here they are remelted in small round street boilers on wheels with a fire under them, to which is added from 30 to 40 per cent. of fine, clean, dry limestone grit. If silicious grit only can be obtained, it should be as fine as sea sand. When ready for use it should be hot enough to vaporise a drop of water. It is carried in pails, and spread, by means of wooden hand floats, over a prepared smooth foundation of 3 in. of concrete (6 to 1) previously allowed to dry. Silver sand is then spread sparingly over the surface and rubbed in by floats. In six hours the footway is ready for traffic. One ton of asphalt covers 30 sq. yd. when laid 1 in. thick, which is the usual thickness adopted for paths. The advantages of asphalt pavements are durability, a smooth surface unbroken by joints, a good foothold, even and regular wear, and an impervious character.

Owing to the substitution of inferior material made from gas tar, Stockholm tar, hard pitch, and ground limestone mixed with bitumen as asphalt, it is essential that the asphalt to form the pavement should be specified to be composed of pure natural rock taken from the mines of the French (or other approved) Asphalt Company.

Bricks. Blue brick-paving for footpaths is one of the oldest materials. Buff granite vitrified bricks, made solely from the fine granite clays of South Devon, have come into general use chiefly owing to their toughness, and their colour, which gives an improved appearance to the paving, presenting a very bright and pleasing effect when laid. Methods of laying bricks to various patterns are shown in 16. [illegible] first essential is the right material, which will produce a tough and hard brick, and this must be treated in a way to develop its best qualities and avoid the defects which in many instances have given paving-bricks a bad name. The firing must have the most careful attention, or in this process the best of material treated by the best methods will be rendered worthless for paving.

Paving-bricks differ from ordinary bricks in that they are thinner, being only 2 in. thick, and are also harder and more compact.

Concrete. By concrete or cement paving is meant the inch of fine stuff which is laid on a coarse concrete foundation.

The use of concrete, as a monolith, as a paving material for footpaths, has made great progress during recent years, and in nearly every town in the United Kingdom, more or less, concrete may now be seen as a pavement. It is one of the cheapest and most durable paths which can possibly be formed.

The following may be taken as a fair description of the manner in which in situ concrete footpaths should be constructed.

Laying Concrete Footpaths. The foundation is excavated to a depth of about 6 in. below the finished level, and a bed of gravel 1 in. in thickness is then laid. A thickness of about 3 in. of clean hard stone is next laid, and well watered and rolled. The footpath is then divided into bays 6 ft. in width with strips of soft wood, and each alternate bay completed by laying upon the stone foundation 2 in. of carefully-prepared concrete composed of one part Portland cement, two parts coarse clean gravel, or other suitable material, passed through a 1-in. screen, and two parts of clean, sharp sand, which must be well beaten into place; and before it is set a finishing coat 1 in. in thickness of concrete, composed of one part Portland cement to two parts granite chippings, is added and brought up to the finished surface of the footpath, being well trowelled and smoothed into place. The strips of wood are removed as the work is finished.

The concrete is thus laid in bays to allow for expansion and to prevent the surface from cracking or gaping open, which is liable on the changes of temperature on large exposed surfaces.

Laying Concrete Paving. In laying insitu concrete paving, the following points should be observed:

(*a*) From October to March is an unsuitable time for laying, owing to the frosty weather.

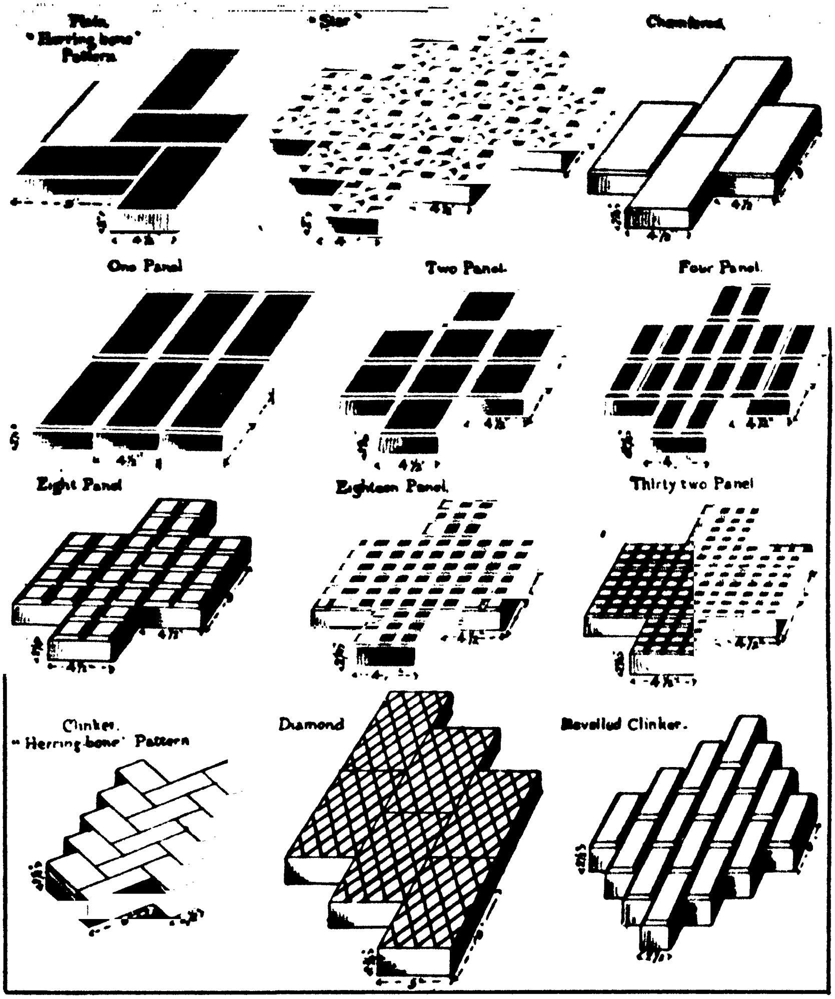
(*b*) It is better to avoid extreme heat, as the sun takes the moisture out of the upper face before the cement has time to set.

(*c*) It is advisable that the ground should be wetted before it is laid, and the finished surface should be protected by damp bags or planks for a week or two before being used for traffic.

(*d*) Beach shingle is preferable to crushed granite, but the sand should be carefully screened from the shingle.

without any signs of wear being visible, and in 1892 a test was made of a portion of the said paving, when 1 sq. ft. was crushed at 562·4 tons.

The paving consists of a layer of Thames ballast concrete, 2 in. thick, laid on a foundation of 4 in. of clinker or brick rubble. On the ballast concrete a layer of granite concrete 1 in. thick is laid, each layer being well worked so as to remove cavities. The surface of the last layer is trowelled to a fair face, which is then sanded and rolled. The concrete is laid and finished off in panels, and can be left either in grey or red colour.



16. CANDY'S BUFF VITRIFIED PAVING BRICKS, SHOWING MANNER OF LAYING

One ton of Portland cement mixed in the proportion of 6 to 1 will cover an area of 42 superficial yards, 6 in. thick.

One cubic yard mixed as above will require 3¾ cwt. of cement, 9 cwt. of sand, 18 cwt. of gravel, and 40 gallons of water.

Fourteen labourers mixing and laying concrete will complete about 135 superficial yards per day of 10 hours.

Stuart's Granolithic. *Stuart's Granolithic* is one of the best known monolith pavings. Granolithic is the name that was coined for the paving by the inventor, who, knowing its great value and qualities, patented it throughout the world.

The surface is indented by the use of a spiked roller, with a view of preventing slipperiness.

During 17 years that a piece of this paving was laid in Leadenhall Street, London, it was computed that 52,000,000 people passed over it

Gravel. Pebble pitching was much used in the earlier periods, and some portions still remain in old county towns. Gravel paths are only suitable for suburban districts. They must be well bottomed with dry rubble, well drained and rolled.

Hoggin from stone quarries, or gravel obtainable from Sevenoaks or Croydon, is the best material for binding and forming a good surface.

A good path for country roads and lanes, and one which is found to be firmer and more comfortable to pedestrians than ordinary gravel and beach paths, is made to the following abbreviated specification :

FOUNDATION. Well formed and left loose.

BOTTOM LAYER. Four inches of chalk, brick rubble, coarse clinkers from furnaces, or iron clinkers from a local foundry, well watered and rolled.

SECOND LAYER. Two inches of fine ashes well consolidated.

TOP LAYER (Finished surface). One inch of finely-sifted ashes, burnt brickdust, or macadamised road siftings, well watered and rolled.

Such a path will wear well, but it is liable to a growth of vegetation.

Artificial Stone. The manufacture of artificial stones is not altogether to be classed as a new art, for our forefathers made use of lime burnt from cockles and other shells to mix with sand. A strong material was made from *terra puzzolana*, imported from Civita Vecchia, and it was with this that John Smeaton cemented together the granite blocks of the Eddystone Lighthouse two centuries ago. As a paving material the merits of Victoria stone cannot be surpassed. It is composed of finely-crushed granite from Groby, in Leicestershire (washed by patent machinery), and Portland cement, carefully selected, and is manipulated and moulded, and subsequently steeped in a patent solution of natural, soluble silica, by which it is hardened, and rendered practically non-porous.

The crystals of the Leicestershire granite are regular in character, being of moderate size, and well cemented by a paste, which the analysis shows to be unusually free from destructive alkaline ingredients. The small size of the pieces of granite used in this manufacture renders the presence of the alkalies practically innoxious, because the artificial cement used surrounds these pieces with a protective coating, and prevents the possibility of any dissolving action by the air or moisture.

Making Artificial Stone. Sample lots of Portland cement are taken and made into briquettes, having a breaking surface of 1 sq. in. These briquettes are exposed to the air for 24 hours and then immersed in water, where they remain for six days, when they are tested by a double-lever testing machine.

The aggregate and cement, having become in a manner guaranteed by the treatment and precautions described, are mixed together in a dry state by machinery, and the water is then added in a careful manner, so as to avoid the danger of washing out any of the fine and more soluble portions of the cement; and before any initial set of crude concrete mixture can arise it is put into the moulds, in which it is carefully worked, in order to fill up the angles and sides, thus ensuring accurate arrises all round. After having remained in the moulds a sufficient length of time, they are taken to the tank in the silicating yard (protected from the weather), and covered by the silicate solution, where they remain until the proper beneficial properties have been imparted.

The machinery required for the conversion of the crude silica into silicate is of a special character. The caustic soda is obtained from the best sources and of the purest quality, because the presence of sulphur, which sometimes exists in carelessly manufactured soda, has a most prejudicial influence on the silicate.

The slabs, after being taken from the tanks, are stacked in the yard, where they remain to season, and are taken away in order of their age.

Varieties of Artificial Stone Slabs. Paving slabs are made of various sizes and thicknesses; those of 2 in. weigh 25 to 26 lb. the foot super, and are convenient to handle.

Street corners are made with patent slabs moulded to radiating and other rectangular shapes to fit the radius, and the difficulties and waste attending cutting the stone at random are avoided [17].

The granite used for the *Imperial* slabs is a mixture of Aberdeen, Guernsey, and Guenast (Belgium).

The *Adamant* slabs are composed of finely-crushed Aberdeen granite and Portland cement. Other artificial stone slabs are composed of finely-broken granite York stone chippings from stone slag and destructor clinkers mixed very accurately with Portland cement and subjected to different processes. Municipal authorities largely manufacture their own artificial slabs by the use of hydraulic artificial stone presses, and with a staff of three men an average of 35 slabs, measuring 3 ft. by 2 ft., can be manufactured in an ordinary working day.

Laying Artificial Slabs. Much depends on the way in which such slabs are laid. Before laying, the area to be paved should be excavated, or filled in with good dry material well rammed, as may be required to suit the intended levels of the path. On this a layer of poor hydraulic lime-mortar is spread, on which the slabs are well and truly bedded. The slabs should be of such dimensions as to break joint when laid [17]. Care should be taken to allow between the paving and building a little space (say, ½ in.), which should be filled in with sand, so as to allow for any disturbance of the ground caused by frost. When laid, the slabs should be run in with grout made from mortar similar to that used for bedding.

Where the natural ground is of clay or chalk it is advisable to put in a layer of ashes or broken clinkers, 3 to 4 in. in depth, to form a dry foundation under the slabs.

The percentage of material broken or cracked in lifting and relaying over pipe trenches is found to be greater with artificial stone than with natural stone. This is partly accounted for by the close joints of the artificial slabs and the brittle nature of concrete. The average waste in artificial stone is estimated at about 3 per cent., but this depends very largely on the manner of bedding and jointing, and on the care used in laying, lifting, and relaying.

Wear of Artificial Stone. Artificial slabs are not found to be more injuriously affected than natural stone by severe frost, and for busy streets this paving is pushing in situ concrete paving out of the field, owing to the practicability of lifting and replacing when electric light, gas, or water trenches have to be taken under the pavement.

The period allowed by the Local Government Board for repayment of loans for artificial pavement seems now to be about the same as that for natural stone. Formerly a shorter period for repayment was given, but this doubtless depends upon the special circumstances in each case.

Natural Stone. For many generations York stone flagging was regarded as the criterion material for footpaths. Without doubt it is the most comfortable to walk upon.

York stones of 3 in. thickness, after being laid for twenty-five years in Kensington, where a large quantity of this stone is laid, were taken up, refaced, resquared, and relaid in a subsidiary street, where they are likely to last another twenty-five years, and the best of it can then be worked up and laid in narrow courses round public parks and pleasure grounds, the remainder coming in useful for road foundation.

It will thus be seen that York has several lives. Lazonby (Cumberland) flags have been in use in Carlisle from time immemorial; they are very durable, and when laid on a good foundation, on a 1-in. bed of good mortar, have been known to wear evenly down from 3 in. to 1¾ in. in thickness; but it is very difficult to get these flags of the same quality as thirty years ago, though whole mountains have been rooted into. Caithness (Scotland) flags are the other only natural stone to compete with York. It has been ascertained that the resistance to a gradually increased bending stress between York and Caithness flagging is in favour of the latter. In the West of England the Devonian limestone flagging is much used.

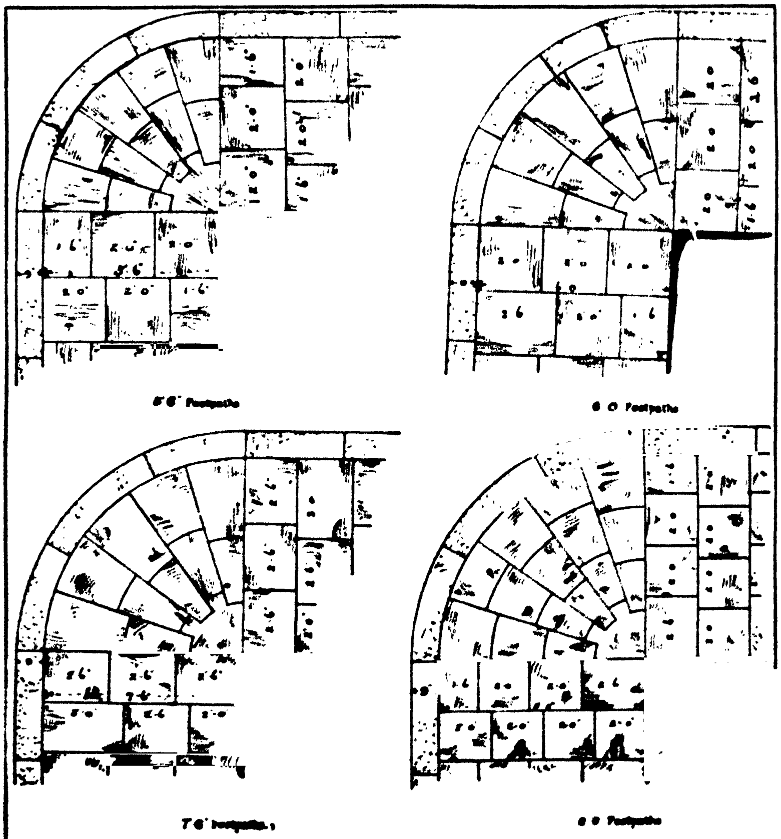
The foundation for flags should be good. Hard core is that most generally employed, and, owing to the uneven surface of all flags, it is necessary to bed on sand. The joints should be set flush, and each stone pointed in properly mixed blue lias mortar.

Tar. Tar-paved footpaths are undoubtedly the most popular formation where the traffic is not too heavy, and the manufacture and laying of this class of paving deserves much more attention than is generally bestowed on it.

In no case should gas tar be used until it has been stored for about six months, so that the volatile oils and whatever water may have been in the tar has had time to escape or come to the surface. The tar should then be drawn from the bottom of the tank.

Making Tar Paving. In manufacturing tar paving the common practice is to heat the stone (Kentish ragstone, Derbyshire limestone, chippings or gravel) proposed to be used in a heap or clamp, the clamp being fired at the bottom, and coke breeze or small coke being mixed with the stone. When the fire is exhausted the clamp is allowed to remain for a few days while it cools, and the heat gets more uniformly distributed.

Another practice is to heat the stone on a hot hearth, on which the stone can be raised to such a temperature that it will absorb as much tar as possible without ignition. Hot tar is added to the heated stove, and the same turned over with hot shovels until all parts of the stone are well coated. Tar paving thus made should be stored for at least three months before being used. In storing, it should be kept as free as possible from damp. Tar paving improves if kept for a year or two, although the nature of the tar, to all appearances, has disappeared. It can be freshened with a little refined tar before being used.



5' 6" Footpaths

6' 0" Footpaths

7' 6" Footpaths

8' 0" Footpaths

17. PATENT ARTIFICIAL STONE SLABS FOR STREET CORNERS

Foundation for Tar Paving. The stones used should be of uniform size, machine broken, and screened; those for the bottom layer should not exceed 1 in. in diameter, and all the stones used should be retained on a sieve of ⅝ in. mesh. The stones for the top layer should pass through a sieve having ⅝ in. mesh, and be retained on a sieve of ¼ in. mesh.

The ground of the area proposed to be tar paved should be levelled, allowing for a fall of not less than 1 in. in 3 feet.

The foundation on which the tar paving is to be laid should be composed of broken brick, ashes, or other similar hard core, not less than 3 in. in thickness, and well rolled until solid, with a fairly smooth and level surface. In situations where there is an existing foundation of gravel or other suitable material, this requires to be *levelled only to falls* as mentioned above for "ground-work," and well rolled; all soft places excavated and made good with suitable hard core, as previously specified for new foundations.

Laying Tar Paving. The tar paving should be laid in two coats, each coat being separately well rolled with a roller weighing not less than 12 cwt. The bottom coat should consist of material of 1¼ in. gauge, and the top coat of material of ⅝ in. gauge. The surface, when being finished, ought to be sprinkled with white Derbyshire spar of ⅛ in. gauge, and before final rolling, dusted over with finely-screened spar or limestone dust, to leave a white smooth surface on completion.

The thickness of the work should vary according to the traffic for which it is intended, and should generally agree with those given below for the various purposes mentioned—*viz.*:

PATHS (*with ordinary traffic*).

Work to be laid 2½ in. thick.

Bottom coat 1¾ in. thick, of 1¼ in. gauge material.

Top coat ¾ in. thick of $\frac{7}{16}$ in. gauge material.

PATHS (*with light traffic*).

Work to be laid 2 in. thick.

Bottom coat 1½ in. thick, of 1¼ in. gauge materials.

Top coat ½ in. thick, of $\frac{7}{16}$ in. gauge material.

Tarring and sanding (or, as it is termed, "dressing") the surface of tar paths should be done during dry weather, the first summer after the tar paving is laid, and afterwards triennially.

The tar used for this purpose should be well seasoned, or refined tar, heated in a caldron, with a little pitch. After the surface of the path is swept clean, and the hot tar well rubbed in, a layer of dry sharp sand, about $\frac{3}{16}$ in. thick, is spread on the tar so as to keep it from adhering to pedestrians' feet. This sand works into the tar, and forms a thin coating, which preserves the life of the path considerably.

Tar pavements must not be compared with asphalt or paved paths, but only looked upon as a substitute.

Roads concluded

STATISTICS OF COST AND WEAR OF MATERIALS USED FOR FOOTPATHS

A STUDY OF LIGHT

Various Theories Regarding Light. Colour. Light Waves. Speed of Light. The Ethereal Keyboard. Shadows. Intensity, Reflection, and Absorption of Light

By Dr. C. W. SALEEBY

THE best fashion in which we can approach the gigantic subject of *light* will be by a brief historical retrospect of our knowledge. To this there needs only the preliminary statement which would establish the parallelism between light, sound, and heat in respect of the distinction that must obtain between the physical and psychological aspects of the subject. There is an objective reality corresponding to light—to what we call light. It is not in itself luminous, but ranges everywhere throughout the universe in utter darkness until it reaches a seeing eye. The blind man enters into sunlight; the light is there, but he cannot see it. If we were all blind, if the human race had happened never to develop the faculty of vision, we should not find it difficult to understand the objective similarity between waves of light, which we happen to be able to see, and the waves which constitute, for instance, the Röntgen rays, and which we are unable to see.

Theories of Light. It is with the great name of Newton that we may begin. In his day there were two rival theories of the nature of light—one known as the *corpuscular* theory, the other as the *wave* theory. The former is also known as the *emission* theory or *emanation* theory, and the latter as the *undulatory* or *vibratory* theory. It was generally accepted, and, of course, still is accepted and proved, that light consisted in the motion of something. This could no longer be doubted when the astronomer Römer, by making observations upon the moons of Jupiter, showed that light took time to travel from one place to another. When this fact was established, it became plain that men must seek for the nature of this something which moves.

The corpuscular theory of light held that the sensation of light is created by a stream of tiny particles which are sent outwards in straight lines from all luminous bodies, and which strike the eye. The wave theory declared that there is no motion of any substance through space, but only that special form of motion which we call wave motion. But this supposition necessitated the further supposition of a something in which the wave occurred—the something which may be called the *ether* or the *luminiferous*—that is to say, *light-bearing ether*. Various other branches of physics lent their support, by way of analogy, to one or other theory. The corpuscular theory was supported by already existing corpuscular theories of heat, electricity, and magnetism. (The reader of the course on chemistry will prick up his ears at hearing of this old corpuscular theory of electricity, for it will remind him of the corpuscles negatively electrified, of which he has there read.) The study of acoustics, on the other hand, lent considerable support to the wave theory of light. Acoustics was already in a comparatively advanced state. The very simple observation that a sounding body is found to vibrate when touched had early led men in the right direction. If sound, then, as no one could doubt, consisted of waves, why not light also?

The Battle of the Theories. Each theory had its supporters, while each certainly had its difficulties. The corpuscular theory of light seemed to be thoroughly compatible with the fact that light moves in straight lines. The geometry of straight lines and their relations corresponded admirably with the geometrical facts of light—its reflection and refraction. The fact of sharp shadows also seemed to favour the emission theory, and to militate against the wave theory.

The great mind of Newton had to choose between the rivals; but, primarily, Newton was not a mere theorist, but a great discoverer, and some of his discoveries in optics tell in favour of the one theory and some in favour of the other. It was in the year 1672 that Newton communicated to the Royal Society his great discovery of the compound nature of white light. As most people know, he darkened his room, cut a hole in the shutter, placed a prism in the path of a ray of sunlight entering, and so broke it up into its component parts. He says, "Light itself is a heterogeneous mixture of differently refrangible rays." Later, he replaced the hole by a slit—though it has been stated that he did not do so—and thus obtained a band of colours.

The Nature of Colour. We cannot do better than quote Newton's own words: "1. As the rays of light differ in degrees of refrangibility, so they also differ in their disposition to exhibit this or that particular colour. Colours are not qualifications of light, derived from refractions, or reflections of natural bodies (as 'tis generally believed), but original and connate properties, which in divers rays are divers. Some rays are disposed to exhibit a red colour and no other; some a yellow and no other; some a green and no other, and so of the rest. Nor are there only rays proper and particular to the more eminent colours, but even to all their intermediate gradations.

"2. To the same degree of refrangibility ever belongs the same colour, and to the same colour ever belongs the same degree of refrangibility. The least refrangible rays are all disposed to exhibit a red colour, and those rays which . . . . exhibit a red colour are all the least refrangible; so the most refrangible rays are all disposed to exhibit a deep violet colour, and . . . . those which . . . . exhibit such a violet colour are all the most refrangible."

In consequence of this pre-eminent discovery and others, Newton inclined towards the corpuscular theory, which we now know to be erroneous. The consequences for the advance of optics were lamentable. For the authority of Newton was so tremendous that the wave theory was delayed, one may say, almost for centuries before it recovered from his opposition. It is true that Newton recognised the objections to the corpuscular theory, but it is the characteristic of the followers of a great man not to see all round the subject as he does, but to jump at his main statement and ignore the qualifications.

The Wave Theory of Light. It was the great Huygens, a contemporary of Newton, who first paid to the wave theory of light the attention which was its due. Thereafter the theory was taken up by the mathematicians, though it never made any real headway until the magnificent work of Dr. Thomas Young, who was led to study light by means of his work upon the subject of the human voice for the purposes of a medical dissertation. This led him to study sound, and he records that he was overwhelmed by the analogy between certain of the phenomena of sound and those of colour. Thus he primarily attacked the subject not from the side of mathematics, but from that of experiment. He was led, however, to the works of the mathematicians who supported the wave theory, and came to the reluctant conclusion that Newton's objection to this theory—and especially the objection that no wave theory could explain the propagation of light in straight lines—could not really be sustained. Continuing to work at the subject, Young made the great discovery of the *interference* of light—a phenomenon which our previous reference to it under sound will make sufficiently intelligible for the present purpose. Young actually found how there are conditions in which the addition of light to light will cause darkness, and its removal will leave light.

Once the facts of interference were established it must surely have been impossible, we would think, for anyone to refuse to accept the wave theory, even though it necessitated the assumption of a luminiferous ether. Lord Brougham, alike ignorant and incompetent, made a celebrated attack upon Young in the "Edinburgh Review," so that, as Dr. Merz says, in his admirable account of the history of this subject, "The doctrine of the interference of light, the mainstay of the undulatory theory, was, like the atomic theory of Dalton, driven out of the country."

An Extraordinary Property of Light. The great labours of Young could not achieve real progress until his work was taken up by the Frenchman Fresnel, who dared to support Young in the very place (Paris) where the corpuscular theory had been so long maintained and apparently strengthened. Fresnel took up Young's experiments, beginning with the phenomena of interference and studying especially the coloured fringes that surround the shadows of small bodies placed in the way of a ray of light. He showed that the theory of wave motion, combined with the idea of interference, was not only compatible with the propagation of light in straight lines—which chiefly led Newton to reject the true theory—but actually explained such propagation. For Fresnel showed that all the sidewards-going waves, or almost all of them, interfered with each other, and so destroyed each other. And now a new difficulty arose. When a ray of light passes through certain crystals, such as Iceland spar, it is split up into two—a phenomenon which is called *double refraction*. Under these and other conditions, such even as simple refraction from any surface, light acquires an extraordinary property which Newton expressed by saying that it has *sides*. It will pass through a second obstacle if that be held at one angle, but not if the second object be then rotated through a right angle.

Polarised Light. Such light, by a very undesirable term, is said to be *polarised*. Now, this remarkable polarisation of light, to which we must, of course, return, would seem to be more or less explicable on the corpuscular theory, if one imagines the corpuscles to have particular shapes just as crystals have. It might be that they were all tilted in one direction or another, and thus could pass through some transparent body at one angle but not at another, just as a stout person may have to turn sideways to go through a turnstile. But the facts of polarisation could by no means be explained on any wave theory which asserted that light consists of waves of alternate condensation and rarefaction in the line of propagation, just as a wave of sound does. One cannot imagine the polarisation of a wave of sound or any similar wave. It cannot conceivably have sides.

Naturally, the discovery puzzled Young, and compelled him to admit that the balance of evidence almost seemed to turn against his wave theory. But Young was not to be beaten, and solved the difficulty in a similar fashion to that which Fresnel himself afterwards independently reached.

The Motion of the Waves. Young declared that if we assume the wave motion of light to be not to and fro in the direction of its motion, but to be *transverse*—that is to say, at right angles to its line of propagation—the facts of polarisation can be readily explained. The apparent *sidedness* of waves of light simply means that, under certain conditions, the transverse vibrations constituting light are deprived of their common character (which is to vibrate in all planes, up and down as much as from side to side), and are reduced to one plane. Let us imagine that this plane is up and down or vertical. We can readily understand that light, the vibrations of which have been reduced to this one plane, will be able to get through a transparent object only on certain conditions. To take an example, a man is mainly vertical, and can readily pass through a vertical door. Imagine the door rotated at right angles, the man will stick, the door will be opaque to him. But if we imagine the man multiplied by many men at all sorts of angles, it is evident that whatever the angle of the door, it will not be able totally to exclude him.

But to disprove the corpuscular theory of light, and to lay down the first foundations of the wave theory, was very far from completing the task. There remained, and still remains, indeed, the all but insuperable difficulty of comprehending the nature of the medium—the light-bearing ether—in which the waves of light are formed. To this subject, however, we need not return, as we dealt with it under Gravitation. At any rate, we have outlined the main features of the great contest between the two theories, and we may now turn to a more systematic study of our subject.

The Speed of Light. A brief discussion of the speed of light may legitimately be placed here, since the discovery that light has a speed at all was absolutely essential to the framing of the undulatory and emission theories alike. It used to be thought that light acted as we still believe gravitation to act—instantaneously. The fact that this is not so had to be discovered before any further advance in optics was possible. In 1675, the Danish astonomer Römer, working in Paris, studying the eclipses of the innermost of the four moons of Jupiter which were then known, found that it did not disappear behind Jupiter and reappear at the moments which he had calculated. The period of occultation varied sometimes by as much as a quarter of an hour. Especially was the moon delayed when Jupiter happened to be on one side of the sun and the earth on the other. The explanation seemed to him to be that when the earth and Jupiter are on opposite sides of the sun, the distance at which the eclipse of Jupiter's satellites is observed is greatly increased. Surely, then, light must take time to travel, and if it does so, not only will the fact explain the apparent delay in the eclipse, but, since the diameter of the earth's orbit is known, the difference between observation and calculation at different times—as, for instance, a quarter of an hour—will readily enable us to calculate the speed of light. By this and many other methods light is calculated to travel at the rate of about 186,200 miles per second. It is a fact of the utmost importance that, as we now know, the onward speed of light is *one and the same with the speed of other wave motions in the ether.*

The Keyboard of the Ether. And here we must dispose of a difficulty which is involved not at all in the physical nature of light, but in the physiological constitution of our own bodies. In the case of sound we saw that the air, for instance, is able to vibrate to and fro at a very large number of different rates per unit of time, out of which we can, so to speak, merely cut a slice, and call it sound. So far as we are concerned, there are sounds which are too low in pitch for us to hear, and sounds which are too shrill. The same is true of light. This perfectly elastic substance, the ether, is able to display transverse vibrations of many, or, indeed, any frequencies per second. From this indefinite series of vibrations we, with our limited eyes, cut out a slice and call it light. In studying sound we saw that the octave of a note has a frequency exactly twice as great as that note. Now, the eye is able to perceive, as light, ethereal waves of a series which just corresponds to one octave. The sound we know has a limit of nine to eleven octaves, but the eye is able to perceive only one octave of light. Above and below this there are more ethereal vibrations, the existence of which we can demonstrate indirectly, but which do not affect the retina, and to which, in short, we are blind, just exactly as if we were able to hear one octave picked out from the middle of the piano and were stone deaf to all the octaves above and below it.

Its "High Notes." The compass or gamut of the ethereal keyboard is daily being extended. Our knowledge of it, at present, is in a curiously imperfect condition; the whole keyboard is there in nature, but we only know, so to speak, a few notes here and a note there. Somewhere in what, for convenience, we may call the middle of the keyboard we have discovered a complete octave—the octave of light. At its upper limit, also, we have more recently discovered a few notes more which, since the last note that we can see we term violet, are distinguished as ultra-violet light, or, more accurately, the ultra-violet rays. Then there is a great gap in the keyboard which we are trying to reconstruct, or, rather, for which we are groping. There is somewhat dubious evidence in favour of the view that a few notes of this gap have been discovered during the past year or two. But if we grope on still further, passing a doubtless complete series of notes which are there, though we cannot discover them, we reach a few very *shrill* tones, so to speak, which are called the Röntgen rays, and which must later be discussed at length.

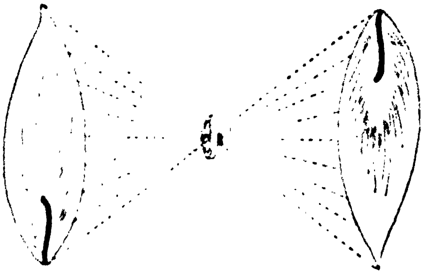
Its "Low Notes." Similarly, if we pass downwards from the central octave of which our eyes assure us, we reach, directly continuous with the red rays—themselves endowed with no small heating power—a series of heat rays. These are of very great variety. The great American physicist Professor S. P. Langley, whose death has just been announced, devised an amazingly delicate apparatus for the study of these ethereal waves, which, if our eyes were somewhat differently constituted, we should doubtless be able to see. The *bolometer* of Langley—an instrument so delicate that it would be able to record, at the distance of a mile and a half, the heat radiated from a human face—enabled its inventor to demonstrate the existence of a long and complicated heat spectrum precisely comparable to the spectrum of visible light. But even below this many notes have been picked out from the ethereal keyboard. Beyond the heat waves we may have to include the so-called N-rays of Professor Blondlot, about which such a furious controversy has waged for two years, and must certainly include electric waves, such as those of Hertz, and those, somewhat longer still, which are employed in wireless telegraphy.

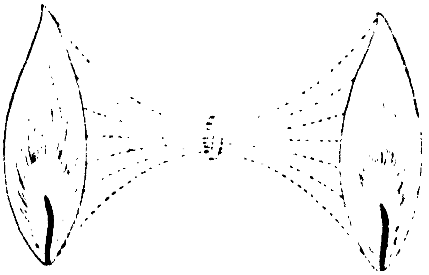
Light and Electricity. Now, the reader must ponder upon the most important fact—already noted—which entirely consorts with the conception that light is only a visible octave, picked out by the eye from a keyboard of incalculable compass. All these rays or waves that we have described, from the Röntgen rays down to the longest known electrical waves, have one and the same onward velocity—the so-called velocity of light. Lastly, we may note that, as the reader of this and the companion course must have guessed, if we are to speak of electric waves and light waves as moving at the same speed and as fundamentally identical, plainly we must make the one term include the other, or invent a common term to include both. The former expedient is perfectly satisfactory, and nowadays we recognise in light, as we shall afterwards see, an electrical phenomenon. The reader will compare this statement with our study of the nature of matter in the course on Chemistry, wherein we came to the conclusion that matter itself must be regarded as an electrical phenomenon. So much for the modern extension of meaning of a term which literally means a peculiarity of amber.

Having discussed the comparatively simple question of the speed of light, having insisted upon the enormous importance of the fact that it has a speed at all, and the scarcely less enormous importance of the fact that its speed is identical with that of a number of other forms of energy which do not at first appear to have anything to do with light, and is, doubtless, identical with the speed of a number of other forms of ethereal wave motion which have not yet even been discovered, we must pass to consider certain of the simplest facts of light; and, first, we may study that striking fact which is so characteristic of light, distinguishing it, apparently, from sound, and which Newton thought to be incompatible with the theory that light is a wave motion.

Light Moves in Straight Lines. This is the fact that light moves in straight lines—the fact of its rectilinear propagation. If we repeat the classical experiment of Newton—at any rate, to the extent of piercing a hole in a shutter—we find that we obtain an image of the sun upon the floor. It is, indeed, an image of the sun and not of the hole, since we may vary the shape of the hole as we please, but will still get the same result. We may notice also, in summer-time, how images of the sun are cast upon the ground by light passing between the leaves of trees. Everyone must have noticed also how, on a moonlight night at the seaside, one may chance to see a perfect image of the moon in any little pool of water that may have been left among the rocks. All these circumstances, not to mention the familiar form of the light which passes from a magic lantern, tend to favour the view that light moves in straight lines. Everyone has noticed this, again, when sunlight passes downwards in straight lines through breaks in distant clouds.

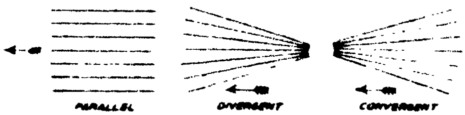
The Inverted Candle. Or we may perform a simple experiment by making a pin-hole in a screen and placing this near a candle, the flame of which is at the same height as the pin-hole. Now we find that the image of the candle is thrown upon any surface that may be placed on the far side of the screen; but it is an inverted image, the candle flame is upside down. This simple and startling experiment has an extremely simple explanation. Any reader can draw for himself the flame and its inverted image, having them opposite one another and placing between them a point, through which the rays from every part of the flame have to pass. If the rays are to pass in straight lines the image must be upside down. The second figure shows the curved course necessary if the image were not to be upside down. The same is true of the image of the sun, if we could recognise it, in the case of our other experiments.





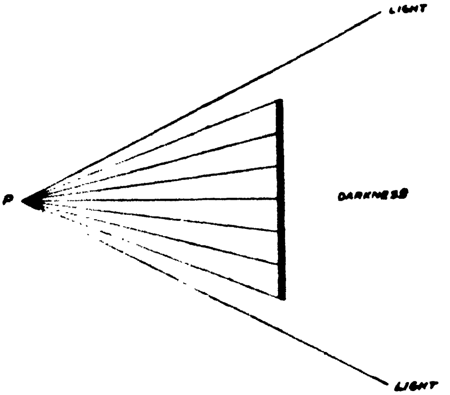
Pencils of Light. Strictly speaking, we cannot speak of a single ray of light, but must conceive of many rays forming a bundle or pencil. The rays in such a pencil may be moving in various directions relatively to one another, though, of course, each is rectilinear. When we refer to a very distant source of light, we may conceive of the rays forming a pencil as parallel. It is true, of course, that the rays filling the pupil of the eye never can be parallel, even when they come from the most distant star. Nevertheless, for all practical purposes, the rays transmitted, at any rate from a star, may be regarded as forming a parallel pencil, and indeed, for the ordinary purposes of eye testing, it is possible to regard as parallel the rays from objects that are not very many feet away. On the other hand, when a pencil of rays has passed through a lens, or when, for

instance, you read this page, the light forms divergent pencils. With a different shape of lens—such as each of us possesses in his own eye—the divergent pencil of rays may be converted into a convergent pencil [see illustration].



In this latter case it is, of course, evident that the rays must meet one another at a point, and this is known as the focus.

Kinds of Shadows. These simple distinctions enable us to understand the variations between different kinds of shadows. When a man makes "rabbits," and so on, with his hands in front of a magic lantern screen, sharp shadows are produced. The sharpness will be absolutely perfect under conditions which, perhaps, can scarcely ever be realised—that is to say, when the source of light is a luminous point and no more. In such a case, since light moves in straight lines, the placing of any object in the divergent pencil of light rays must necessarily produce an absolutely sharp shadow. There can be no complication, as the accompanying diagram shows. A certain number of rays are cut off by the obstruction and a certain number escape. But the moment the source of light becomes anything other than a point, then every one of its points behaves as does the luminous point in the diagram; and thus sharp shadows cannot be obtained. Thus, in the celebrated case of eclipses of the moon, where the earth intervenes between the sun and the moon, and where the eclipse is due to the falling of the earth's shadow upon the moon, we discover two distinct areas of shadow, one dark and known as the *umbra* or shadow, the other less dark, outside it, and called the *penumbra* or almost-shadow. In the case of the part of the moon which is covered by the umbra, the whole of the sun's light has been cut off. The area covered by the penumbra is cut off from part of the sun's light but not from all of it. If the sun were a luminous point, there could no more be such a penumbra than in the case of the accompanying diagram. If the reader will draw a second point, just above or below the point in the diagram, and then draw similar rays diverging from it, he will see how a penumbra or an indistinct edge to the shadow must necessarily occur.



Shadows of Sounds. And one more point concerning the rectilinear propagation of light. We have observed a contrast between sound and light, and have commented upon the very great discovery of Fresnel, which demonstrated that this rectilinear propagation is compatible with the wave theory of light if we assume the waves to be transverse, and if we invoke interference to explain the mutual destruction of all or nearly all sidewards-going waves. The point is, that we must not be confused in our notions of the movements of sound. As daily life teaches us, and as the study of echoes confirms, sound also moves in straight lines mainly. Thus, for instance, it is quite easy to produce what may be called shadows of sound. This fundamental fact of the rectilinear propagation of energy must never be forgotten if we are to hold intelligently Newton's first law of motion. We must connect in our minds not only the movement of a bullet or a planet, not only the movement of the molecule of a gas, which always goes straight on until it strikes something, but also those movements which we class as wave motion, whether these be to-and-fro waves in material media, or transverse waves in the ethereal medium.

The Intensity of Light. The reader will readily be able to guess that there is a simple law which determines the variations in the intensity of light with distance, and also the exact statement of that law. It needs only to remember the law of gravitation and the similar facts in the case of radiant heat and sound. The intensity of light varies at any point inversely as the square of the distance from the source of light. It can be shown that this must be so, whether the corpuscular theory or the wave theory of light be true. Various means have been adopted for estimating the intensity of light at any point. Such means are technically known as *photometers* (Greek *phos*, with root *phot-* light).

Perhaps the oldest and simplest photometer is that invented by the celebrated and remarkable man Count Rumford, an American, who came to England and was a leading spirit in founding the Royal Institution. His real name was Thompson, a name which, sometimes with and sometimes without the "p," is also borne by three of the most distinguished of living physicists. Rumford's photometer is simply, in its essence, a screen of white paper, in front of which is placed an upright stick, capable of casting a shadow. If two sources of light be placed beyond the stick, two shadows will be cast. The eye is then able to compare the depth of the two shadows, and it is found that when sources of light of various strength are used, the law of inverse squares is confirmed. This may be done by employing a standard source of light, such as the *standard candle*, to which we refer when we speak of candle power. On the other hand, if we assume the truth of the law of inverse squares, the photometer enables us to value or appraise the illuminating power of any new source of light. Another device is that of Bunsen, and depends upon the fact that a grease-spot on a piece of paper looks lighter than the rest of the paper if one looks through it at a source of light, but darker if the light and the eye be on the same side of it. Thus the intensity of light produced by two rival sources of illumination, one on each side, is equal when the grease-spot cannot be seen at all, and their value can be measured if their distances be compared. Very many photometers have been invented since these days, and those now used are very much more sensitive; but it would require a lot of space to describe them properly, and they introduce no new principle.

The Reflection of Light. And now we reach a more difficult inquiry. We shall be able to elucidate some of the laws of the reflection of light, or, at any rate, to define them. But we must not be confused into thinking thereafter that we have really arrived at a complete knowledge of the subject; for observe the complication that is introduced. We are discussing, not light in itself, but the relation between light and material bodies. Since all our views as to the structure of matter are in the melting-pot, it is evident that, though we may be able to use terms and define them, we are very far indeed from being able to explain the facts which they indicate. Take such terms as *transparent, translucent,* and *opaque*. We know what is meant by the first, though the ideally transparent substance has yet to be found. A lens of glass or the transparent structure at the front of the eye will let through by far the greater part of the light that falls upon it, yet some light is always thrown back or reflected, and in so far the lens is opaque.

The terms are relative. A substance which is translucent occupies an intermediate place, but obviously there is no hard and fast line to be drawn between ground glass and the glass of our window-panes. The difference between the transparent and the translucent glass is this, that the light passes through the first without being distorted or scattered, whereas the translucent body allows the light, or most of the light, to pass through so that objects seen through it have their form proportionately distorted or entirely obliterated. Bodies are visible—for instance, a pane of glass is visible—exactly in so far as they are not transparent. If the pane be perfectly transparent—to approach which condition at all it is necessary that it be perfectly clean—it is necessarily invisible.

Light and Water. These terms will help us to return a simple answer to the question why water has different relations to light according as we look at the surface of an unbroken wave, or at the foam which is formed a moment later. The poet speaks of "Light dissolved in star showers thrown," but we must have a more scientific explanation. Foam is opaque, though merely consisting of water, and is incapable of reflecting the form of any object, simply because it contains a multitude of tiny bubbles. One result of this is that there is repeated and incessant reflection of the light that tries to pass through it, since a certain amount of light is always reflected when it passes from one medium to another, in this case alternately water, air, water, air—and so on. In the second place, the foam does not act as a mirror, because its many bubbles reflect the light in all directions, and so destroy the form of the waves that impinge upon them.

Now, in discussing heat, we saw that certain bodies are transparent to heat, or, to use the technical term, are *diathermanous*. We saw that diathermancy and transparency are not necessarily the same for any substance, the difference ultimately depending, of course, upon the fact that the waves of radiant heat are somewhat longer and less frequent than the waves of light.

Absorption of Light. But we also saw that radiant heat may be absorbed. If we compare water and bisulphide of carbon, of which the former is opaque to radiant heat, while the latter is *transparent*, we find that when these are respectively exposed to the action of radiant heat the water is heated, whereas the bisulphide is not. In other words, the heat has been absorbed by the water. This means, of course, that the energy is arrested, but is not destroyed. The law of the conservation of energy must be obeyed everywhere. Now, the case is exactly the same with light. A body may let light energy through it, or it may throw back the light energy from its surface, or it may do neither. It may arrest the light energy and keep it. Now, of this we are absolutely certain, that the light energy is not destroyed. What becomes of it, then? We find that the body is heated. It is simply a case of the transformation of energy, the light energy being converted into heat energy. It is also a case of the degradation of energy or the dissipation of energy, heat being the lowest, least available, form of energy, and that to which all other forms, as we have seen, appear consistently to tend.

DRESSMAKERS

Although at the present day the field of commercial enterprise offers many and varied opportunities to the woman who is desirous of earning her living—and practically any form of employment is open to her—still, with few exceptions, women workers have confined themselves to the various businesses in which they participate with their own hands, such as dressmaking, millinery, cookery, and laundry-work, in preference to those occupations where organisation and direction only are required, and the great majority of them have achieved success as dressmakers. The past twenty years or so have also witnessed the entry of society women into the commercial world, and in most cases they have proved themselves capable and efficient. It is one of the signs of the times that an aptitude for business, and the capacity for success in trade, should no longer be looked upon as evidences of plebeian origin and the peculiar attributes of the middle or lower classes, but are now envied qualities in many clever, hard-working women of good birth and recognised social position, who have elected to turn those talents to account in the domain of dress or millinery.

Classes of Dressmakers. The term "dressmaker" includes all sorts and conditions of women, from the wealthy Court dressmaker of Portman Square or Mayfair to the poor workwoman "plying her needle and thread" in the top room of a tenement house. They may, roughly speaking, be divided into three classes. First, those who have received little practical training, but have acquired a business by purchase, and employ subordinates to carry out their instructions and do the work for them; secondly, women who have been thoroughly trained, either by apprenticeship or special arrangement, and who have set up and formed a connection for themselves; and, thirdly, dressmakers who do not start an independent business of their own, but obtain employment with other dressmakers, or in the costume department of one of the large drapery houses.

Starting in Business. To start a high-class dressmaking business in London, it would be necessary to have at least £1,000 capital, especially if the locality chosen be in a West End neighbourhood, as such a position would entail high rent; and a fashionable dressmaker in town is always supposed to give three months' credit, and is frequently obliged to give six months. It would be unwise for anyone to start for herself without having at least three years' experience with a good firm. She should be an accurate cutter and fitter, possessing the artistic faculty to some extent, and having a correct eye for colour; should have a practical knowledge of trimmings, laces, etc.; and thoroughly understand the intricacies of buying and selling, the preparation of estimates, and all the details necessary to the successful management of a business. The stock kept need not be large, but must be well chosen and varied. An introduction should be obtained to a good wholesale firm, who would supply books of patterns of all goods, and send any lengths required on receipt of orders. Quarterly accounts are sent in, but when good references are given the wholesale houses often take half-yearly payments. A good system of bookkeeping is most important. If the head of the establishment should not be well qualified in this respect, a competent bookkeeper might come once a week or so until increase of work would necessitate the engagement of a permanent bookkeeper and stockkeeper combined.

Equipment. To set up in a provincial town, or in the suburbs, a smaller capital would suffice, as rents would be considerably lower, and wages to the workers not so high, while the chentèle would probably include a number of ready-money customers. To begin in a small way, it would be possible to manage with two good-sized rooms, one for a workroom and one for a show-room. A small room for fitting would be desirable, but if this should not be attainable part of the show-room could be screened off for the purpose. A treadle sewing machine (Jones' or some other approved pattern), two dress stands (one small and one a fairly large size), a tailor's goose, irons, a skirt-board, two tables (one for the workers and one for cutting out), together with a large cupboard for hanging up the work are a few of the things necessary for the work-room. In the show-room there must be a long glass, a couple of cupboards or a number of deep shelves for keeping stock, a writing table, with account books, bill files, etc., and usually a kind of counter on which goods can be displayed, together with a good supply of fashion papers and magazines, including the best Paris and Vienna journals. Such things as bones, bone casing, hooks and eyes, cottons, machine silks, pins, and dress patterns must be bought in fairly large quantities at first, and a sufficient stock should always be kept in hand, as workers must never be kept waiting for small items of this kind.

Assistance. To begin with, one competent general hand, who can work at skirts and bodices, and who is a good machinist, should be engaged. Her wages to commence would be from 16s. to 18s. a week; and an apprentice, who would run errands and make herself generally useful, would be paid about 2s. a week at first. When a few orders come in another worker should be taken on, at about 8s. a week, to work under the first hand, and so on as the work increases.

Apprentices are usually taken at the age of 14 or 15 years. In a good house a premium is required. The apprenticeship period usually lasts two years, at the end of which a girl may be taken as improver for six months, or less if special quickness is shown. An improver is paid, on an average, 8s. weekly. She will then obtain a position as assistant, at from 8s. to 16s. a week. From this her advancement will be rapid or otherwise, according to her individual capability and industry. There are always well-paid posts to be had by the skilful and well-qualified workers. Of these, one of the most desirable in many ways is the position of head fitter in the dressmaking department of one of the large drapers. Only an expert is chosen for such a post, and she is expected to make the department pay. She is usually given a free hand in the matter of engagement and management of workers; and in this connection it may be said that the most advantageous results are generally obtained from the assistants who are treated with the greatest consideration and kindness by their chiefs. A great deal very often depends upon getting out work within a given time, and this can best be done when the willing co-operation of the workers is secured, as, by the provisions of the Factory Acts, they cannot be compelled to stay beyond certain hours, yet they will often do so voluntarily, to oblige. Sometimes the fitter receives a commission on the work, and generally the salary paid to a satisfactory person is very good. An ambitious woman can frequently save enough money to enable her to start in business on her own account, where her prospects of success will be considerable, owing to her proved ability and her experience in dealing both with work and customers.

Women who have absolutely no means of obtaining any money to start with sometimes begin by taking work at their own homes. They only buy for immediate use, and are at once recouped by their customers so that they are not obliged to expend any money on materials. They often commence by making nurses' uniforms and servants' dresses, and in time some of them manage to build up a very fair business entirely through their own exertions.

Customers. Friends will probably form the earliest clients. They will come at first from friendship, or from curiosity, but if they are pleased with the work done, and if their orders are always executed with promptitude, they will continue to give their custom, and will tell their friends to come also, and so help to establish a connection. Sometimes a good method of securing business is to mention on the cards or notices sent out upon starting that ladies' own materials will be made up, and that *renovations* will be undertaken at moderate charges. This will often gain a fresh customer, as many people who might hesitate about entrusting an unknown dressmaker with a new frock would be very glad to try her capabilities in renovating an old one, and will then give further orders if the work is satisfactory. When the connection grows large it will be easy to give up the renovations, or, if they are found profitable, a separate department might be opened for this branch of work.

Some Hints. January, February, August, September, and sometimes October, are bad months. In slack times odds and ends of silk, lace, and net can be made up into little jabots, sleevelets, waistcoats, etc., and, provided that they are chic and up-to-date, will find a ready sale in the show-room if the prices are kept low. At the end of the first year it will be easy to see which customers may be trusted to run up bills, and which of them it would be wiser to be always "too busy" to work for. As the business increases a certain amount of selection can be exercised in the choice of customers, and those who are troublesome and fidgety, or who are bad at paying, can be struck off the books. Dressmakers living in the provinces should make a rule of coming to London at least three times a year, and, if possible, pay an annual visit to Paris.

ELECTRIC DEALERS

The man who makes electrical fittings his speciality must be more of a mechanic than a merchant; but the shopkeeping side of the business is not altogether lost to view in the more important departments, and a review of the shopkeeping trades would be incomplete without a brief consideration of the requirements and opportunities offered by the field of domestic and industrial electricity to the mechanic with scientific bent and average intelligence. The technical training of the electrical engineer is considered in another part of the SELF-EDUCATOR.

Departments. The two departments of the business are the *selling* and the *working* sides, and both again are divided into many varieties of work, from the simple electric bell to the complete installation of a complete generating plant. The order in which the classes of work come—from the simplest to the most complex—are bells, telephones, and the installation of lighting and power work. The degree of technical skill and the amount of capital required by the man who would set up as an electrical engineer are proportionate to the departments he intends to exploit.

Bell and Telephone Work. Let us take the simplest case first—the man who is engaged in one of the lighter mechanical trades, say that of a plumber, gasfitter, bellhanger, blacksmith, tinsmith, or cycle agent, and who would expand into electrical work. He would probably content himself with undertaking electric bell and simple telephone work. His technical knowledge need not be extensive, and his capital, applicable to this department, may be very small. A few hand tools, the majority of which he will probably possess already, a few coils of insulated wire, some bells, pushes and batteries, and he is practically ready to invite custom. The whole outlay need not exceed £10, and half of this might even suffice. The principles governing bell work are simple, and may be learned by a few hours' study and by a few half-hours of practical experiment.

A higher step is reached when the man is able to undertake complicated telephone work such as intercommunication and switchboard system.

Wiremen. Then, in most towns where current is available there are many firms who occupy, in a different sphere, positions on the same plane as the gasfitter. They fit up houses with wires and electric light fittings, making all the necessary connections with the service mains, but take no part in installing plant to produce electricity or in making or repairing such plant.

For this class of work practical experience is almost essential. A good knowledge of theory may serve, however, if the man have considerable mechanical skill, and many electricians have begun in this way; but the probabilities of success without the practical training are now smaller than they were when the trade was in its infancy, and when fewer practically trained men were engaged in the work. The man must have a smattering of several trades. He must be something of a joiner to be able to lead his wood casing properly and neatly, he must be adept at pipe fitting for his metal conduits, and he must have an intimate general knowledge of the construction of houses, so that he may run his wires as accessibly, economically, and efficiently as possible.

The Electrical Engineer. Finally, there is the man or firm who combines with special electrical knowledge the skill of a mechanical engineer and who undertakes all varieties of installation and repair work, and may even do a little manufacturing on occasion. This man requires a proper workshop equipment similar to that of a mechanical engineer. He must have, say, a small turning lathe, a vertical drilling machine, a small planing machine, and a polishing plant, involving an outlay of about £80, not including a power engine—steam, gas, oil or electric—depending in nature and cost upon local conditions.

Essential Qualities. The installing of electric work requires care in a supreme degree. An installation contains many independent pieces of complicated mechanism. It may be easily put right if slightly deranged, but it is easily put out of gear. A screw become loose by vibration may hold up a large factory. Precision in the material and its fitting is essential. Hence, the man capable of this precision is alone likely to be a successful electrical engineer.

Conscientious work is as essential as precision. There is plenty of opportunity to scamp the work—more than formerly. The wiring of old buildings had to be chiefly surface work, which is, in spite of all that may be said, the better in that the wires are more accessible to inspection. But when new buildings are to be fitted with electric installations the work is largely concealed, and an unscrupulous wireman may save a little time and money by carelessness. But this is sure to come back to his hurt, and a man with a reputation for bad work might as well shut up and begin a clean slate elsewhere.

The Pure Merchant Side. The pure merchant side of the business of an engineer represents a very small part of his interests, and there is very little scope for the man who can take up only the selling department. For this side practical knowledge of electrical science is not essential, any more than a knowledge of tailoring is essential to a draper. Electrical engineers find that the pure sales department is a very small item in their business. The profits it yields are seldom more than pay shop rent, and most of them would discard it altogether if it were not for the indirect profit which follows. The possession of a shop and of a sign bearing the words "electrical engineer" or "electrician" serves to keep the man before the public eye, and this is most important for a new man pleased at first to undertake small contracts. The competition by many municipalities and electric lighting corporations in supplying consumers with lamps and electric fittings, and even in offering wiring, subject only to one annual rent charge, restricts the opportunity of private venture. The electrical departments of municipalities frequently sell fittings at cost price, relying for profits upon the consumption of current. This form of competition is particularly obnoxious to the private trader, and is a standing grievance in many districts. The practice has, however, become too firmly rooted to be suppressed, and probability is all in the direction of its expansion.

The Stock. The nature of the stock for the merchant side must depend upon the extent to which the supply companies in the neighbourhood—municipal and otherwise—cut into the trade and the policy they pursue. Assuming that the field is fairly free from this form of competition, the stock will consist of electroliers and fittings, switches, lamps and their fittings, telephones and their accessories, and bells and their oddments. An expenditure of £200 will purchase a good all-round equipment for a middle-class trade, and half of this sum may suffice for a modest start. The sum will depend upon the variety of the more expensive stock held. Electroliers, for instance, cost a deal of money, and half a dozen good examples will make a large hole in the capital. When the electrical merchant or engineer is in or near a city, he may spare himself some capital outlay by arranging to have his customers visit the show-rooms of the manufacturers or large factoring houses who hold a variety to which he cannot aspire, and who are always willing to sell for him and to reserve to him his legitimate profit.

Buying. Extreme caution is necessary in the purchase of stock. Cheapness usually means nastiness and trouble laid up for the future. In incandescent lamps, for instance, while good varieties, such as the Ediswan, Sterne, and Robertson, will give satisfaction and help to make a reputation for their sellers, cheaper varieties, which may even pay better, may either estrange customers, or bring them back with a demand for free replacement.

Novelties, also, should be received with suspicion. There is in the electrical trade the same demand for novelties and improvement that prevails everywhere, but there is this difference—that electricity, being a comparatively new science, and not yet understood so well as the mechanical sciences, is the field of experiment as no other is, and much experiment means many failures.

Where to Buy. The beginner will find it convenient to patronise the houses who supply everything from a bell push to a dynamo, and there are several such. The practice makes only one account, and by having one good account a man is more likely to have good attention than when he has a multiplicity of small ones. Also he is more likely to receive consideration should he find himself in a technical difficulty and ask advice thereon. But as he grows in importance the dealer or electrical engineer will find that he can do better for himself by purchasing dynamos from dynamo makers, transformers from their manufacturers, lamps and telephones from the respective factories where they are made instead of from the general wholesalers with the "needle to an anchor" variety.

Profits. A frequent discount by makers and factors is 33⅓ from list price with an extra 2½ per cent. for monthly payments. To the casual buyer there will be no cutting unless the seller be foolish There is no occasion for it. But to large buyers and regular customers list prices can seldom be maintained.

The bulk of the business will probably be found to be a matter of quotation, and certain commercial principles should guide the casting up of an estimate. It should be recognised that goods taken from stock ought to carry a heavier profit than articles which may be ordered on direct from the manufacturer to the "job."

Labour, again, should carry a higher profit than either of the two classes of goods mentioned. A fair average profit to apply to the three departments of a working job are as follows:

Goods taken from stock, 25 per cent.

Goods got in direct for the job, 15 per cent.

Labour, 33⅓ per cent.

These rates of profit are satisfactory, but by no means exorbitant. The electrician who goes below these rates as a general practice may make a living at his business, but he will scarcely gain a competency.

The rates we have given take no account of the uncertain "contingencies" which arise in every job. In exact calculation there should be nothing under this head in the materials required. It ought to be possible to include in any new work all material to the last screw and nail. But with time it is otherwise, and the estimate of time should always be liberal if the probability of loss would be avoided, and the profit on labour should be added after the liberal time estimate has been made.

Rules to be Followed. There are certain defined rules which the electrician in any district must follow in his practice. These are framed upon the requirements of public safety. They are seldom onerous and must always be known. There are the requirements of the fire insurance companies, who will accept a policy upon a building containing an electrical installation only if the equipment has been made in accordance with their rules.

The regulations of the Phœnix Fire Office are frequently taken as the standard.

Then each corporation or other electrical service company issues regulations to which any building electrically equipped must conform before they will permit connections to be made with their service mains, and the electrician must ascertain what these are in his individual district. The requirements of the Board of Trade are incorporated in the rules issued by the assurance companies and the supplying companies or corporations.

Reference Works. Every electrician must provide himself with some textbooks to guide him in his practice. The technical handbooks on electricity are legion and we cannot attempt to enumerate more than very few here. For a general concise survey of the principles of electricity and of electrical engineering practice, nothing better than the course on Electricity by Professor Silvanus P. Thompson in this work can be consulted. The most exhaustive and up-to-date authority covering the whole field of the generation of electricity and its industrial uses is the work in five volumes, "Electrical Installations," by Rankin Kennedy, C.E., published by the Caxton Publishing Co. Good books upon various departments are: "Dynamo-electric Machinery," by Silvanus P. Thompson (Spon), 2 vols., 30s. each. "Central Stations," by C. H. Wordingham (Griffin & Co.), 24s. "Primary Batteries," by Cooper (Electrician Co.), 10s. 6d. "Continuous Current Dynamos and Motors," by W. R. Kelsey (Technical Publishing Co.). "Practical Electric-wiring for Lighting Installations," by Charles C. Metcalfe (Harper), 5s. "Practical Electric Bell Fitting," by F. C. Allsop (Spon), 3s. 6d. "Telephones: Their Construction and Fitting" (Spon), 3s. 6d. "Electric Lighting and Power Distribution," by W. Perrin Maycock (Whittaker), vol. 1, 6s., vol. 2, 7s. 6d. "Electric-wiring Tables," by W. Perrin Maycock (Whittaker), 3s. 6d. "Electric Wiring," by W. C. Clinton, B.Sc. (Murray), 1s. 6d. "Modern Lightning Conductors," by Killingworth Hedges (Crosby Lockwood), 6s. 6d.

SPINNING TEXTILE YARNS

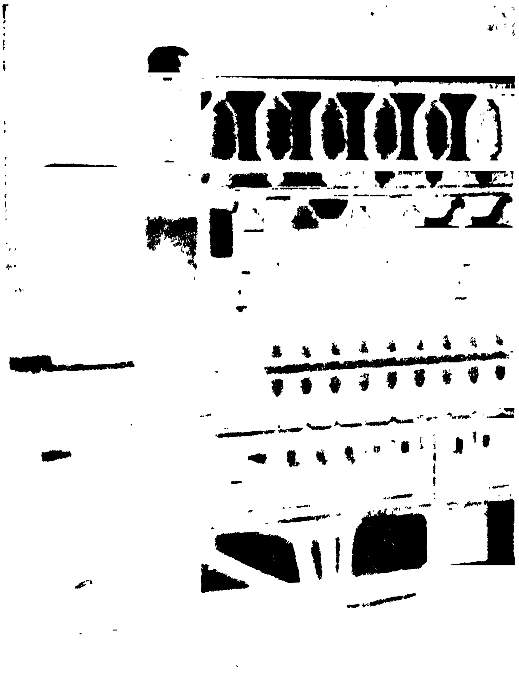
Spinning Machines: The Throstle, Cap Frame, Ring Spinning Frame, and Mule. Production of Cotton, Woollen, Worsted, Waste Silk, Linen, Rope, and Jute Yarns

By W. S. MURPHY

Spinning Machinery. Essentially, the whole process of forming fibres into yarn is spinning; but the work has been broken up into parts, and each division has been given a different name, the general term being reserved for the last of the series. As now understood, the spinning frame is the machine which finally draws, twists, and spools the yarn. It is important to note that there are three acts in the operation. Those acts may be performed simultaneously or successively, and the alternatives mark the difference between the two classes of spinning frames in use.

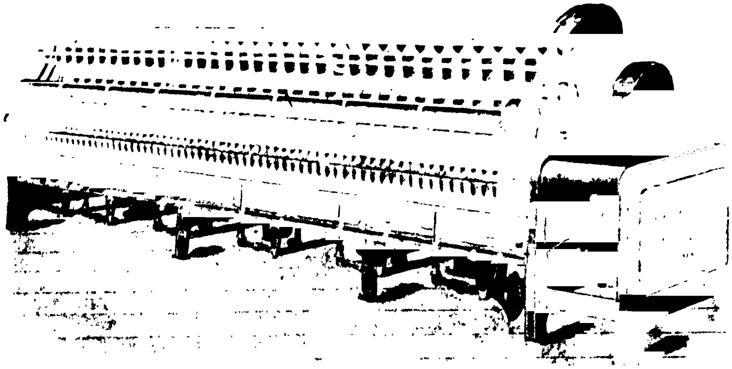
Abstractly, we should say that the machine which performs the whole operation at once is the better; but in actual fact the machine which proceeds automatically from the one act to the other is universally admitted to be the superior. Arkwright's water frame and Crompton's mule were the progenitors of the two opposed types. The strenuous organiser of the cotton factory aimed at producing a machine which would spin and spool the fibre in one operation. On the other hand, the gentle Crompton was content to accomplish the purpose in three successive steps. The present-day representative of Arkwright's contrivance is the *throstle* spinning-frame, of which we have several varieties. Crompton's mule is still the "mule," but it has been improved beyond recognition.

Throstle. This frame [89] is upright, and in three divisions. On the top are the fixed spindles which hold the bobbins of rovings, collectively called the *creel*. Midway we find the drawing rollers, similar to those on the drawing frames, but finer and swifter. The third tier is composed of spindle and flyer, bobbins and lifter plate. Note, however, that bands from a horizontal cylinder run through the whorls on the spindles only, and that no drive is carried to the bobbins. From the creel above the rovings pass down through the drawing rollers, and the attenuated thread is coiled round the leg and on to the hook of the flyer. Next it is lapped round the bobbin by hand to give it grip, and then the work begins. We see that the flyer is attached to the bobbin by the yarn, and if that were all, the bobbin would be bound to follow the flyer. But the yarn which is the cord of attachment is being given out from the drawing rollers. In order to keep up with the flyer, the bobbin must wind on the amount of slack constantly being paid out from the rollers and through the hook of the flyer. Of course, having no motion of its own, the bobbin must obey the combined rule of the roving and the flyer, and wind itself full. A traverse lifter-rail conducts the yarn evenly on the bobbin, moving up and down in regular motion across the whole frame.



89. THROSTLE SPINNING FRAME
(H. Bannerman & Sons, Manchester)

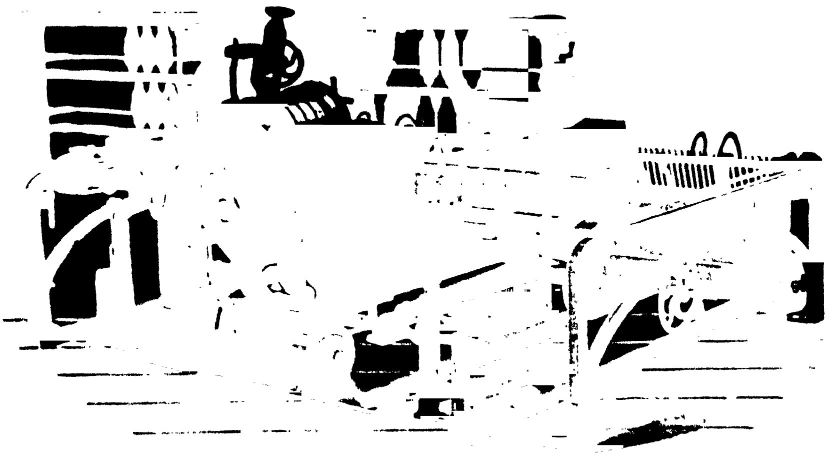
Cap, or Tube Frame. Originally the patent of an American named Danforth, the cap frame was patented and improved in this country by Mr. J. C. Dyer, of Manchester, in 1825. Instead of the flyer, this machine has a cap fixed on the spindle, the cap acting like a lever on the bobbin, which has its own driving gear. The tube frame is an early example of the daring genius of the American mechanic; where the steady British inventive imagination depends only on steel or iron for action, the Transatlantic contriver trusts to intangible force. From the drawing rollers the thread is fastened on to the bobbin, which, having a motion of its own, draws the thread with it. But this would never form a spool. It is here the characteristic genius of the American appears. The cap is being driven at high speed, and it encloses both bobbin and thread. By the motion of the cap a centrifugal force is developed which winds on the thread, and the cap, moving up and down on the bobbin, distributes the yarn as evenly as possible all over the spool. A gradual reduction of the traverse of the cap produces the sloped ends, which are much favoured on all bobbins.



90. RING SPINNING FRAME (Platt Bros. & Co., Oldham)

Ring Traveller. The simple and rather haphazard winding method of the throstle was further improved upon by the invention of the ring traveller. Otherwise the construction of the frame [90] is unaltered. The various parts are distributed in this way. The bobbin sits on the spindle, which passes through the bolster rail, and is driven in the usual way. On the lifter rail, however, we find a ring with flanged rims, and within the rim a little hoop of steel grips with hook ends. The ring is wide enough to let a full bobbin through, and the hoop, or traveller, slides easily on the ring. When brought down from the guide eye the thread is passed through the hoop, and thence on to the bobbin. When the bobbin begins to whirl round, it cannot drag the thread round itself, except at such a rate as the ring traveller will permit. The drag of the little hoop is not great, but it is sufficient, and the revolving motion of the latter imparts a twist to the thread. Besides giving the thread the twist required, the traveller has another function to perform. Borne on the lifter rail, which moves up and down over the length of the bobbin, the traveller carries the thread in such a way as to distribute it evenly over the bobbin [93]. The ring spinning frame [90] shows double rail, patent flexible spindles, inclined roller stand, and the Birkenhead creel.

The Mule. Having been public property for over a hundred years, the spinning mule has been brought to a high pitch of perfection. Machinists, unable to patent any one of the principles, have been compelled to fall back on the expedient of producing the highest class of machine. As a result we have what has been described as the finest mechanism ever invented by the wit of man. In regard to the mule itself it is not necessary that the student should become acquainted with the various and intricate mechanical details. To exhibit these properly, we would require to explain several complex mechanical problems, and show many diagrams, while at the same time adding but little to the student's knowledge of cotton spinning. The headstock, in which the whole of the mechanical parts reside, is not the concern of the spinner so much as the engineer. Our business is with the spinning frames.



91. SELF-ACTING COTTON MULE—RUN AT BACK (Platt Bros. & Co., Oldham)

Working the Mule. First, we note the working of the self-acting mule [91]. The rovings are placed on the creel at the back of the upright, stationary part of the mule. Led through the guide wires, the threads are passed in between three pairs of rollers, and on to a range of bare spindles. Before we examine the spindles, we should pay close attention to the drawing rollers. Closely resembling the drawing rollers of the drawing frame, the mule rollers have special features of their own. The first pair merely grip on the thread and feed it to the second pair. This is necessary, because the roving bobbins have no power of resisting the draft. The second pair move more swiftly, but not more than is needed to hold the threads tight and draw them slightly; the third pair revolve at a much higher speed, attenuating the threads, and feeding them to the spindles.

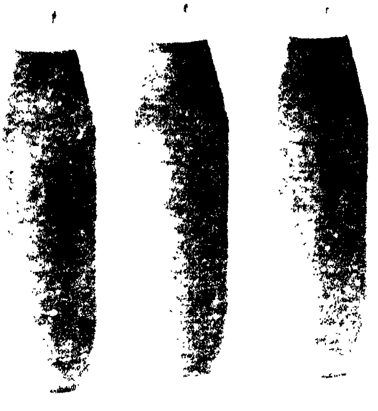
Note, further, that all these rollers have the power of stopping as soon as a certain fixed amount of thread has been given off. The reason for most of these particulars is to be found in what we may describe as the other half of the mule. This is a carriage borne on wheels running on rails. The average run of the carriage—the stretch, as it is called—is 64 in. in the case of cotton, and a few inches less for wool. On the top of the carriage, leaning slightly towards the frame, sit the spindles which take on the yarn as it is delivered from the rollers. Starting from close up to the frame, the carriage bears the spindles away, taking up the yarn, and stretching it across the widening space. Just before the limit of the run, or stretch, has been reached, the rollers stop and cease to deliver thread, the carriage slows, and the spindles rapidly revolve, twisting the thread. The whole machine stops for the fraction of a second, and the spindles perform a kind of reverse movement, unwinding the threads that have got wound on the tops of the spindles. At this moment a faller wire comes up, and helps the threads to lift off the points of the spindles. This done, the carriage begins its return journey at double speed, the spindles reversing their movement and winding on the threads, while another faller wire comes down to press down the threads and send them on to the body of the spindles, so as to form a regular cop.

Spindles. Every spinning machine, slubbing, intermediate and roving frames, throstle, ring spinning frame, cap frame, and mule has its own special spindle. In **94** we have an assembly of the chief types of spindle, arranged in something like the order of their development, though not exactly. There is a special feature in the "Rabbeth" to which attention must be given. In an ordinary spindle, by capillary attraction, the oil which lubricates the spindle is drawn up, and stains the bobbin and the yarn; to obviate this the "Rabbeth" has been devised. In No. 10 of the figure the structure is most obvious; there we see the sleeve with its hollow cup round the spindle. The bobbin sits on the rim of the sleeve, which takes in all the oil, and by its hollow shape tends to preserve the lubricant. No. 11 is another device directed to the same purpose. When we come to the doubling department, we shall see various forms of these spindles at work.

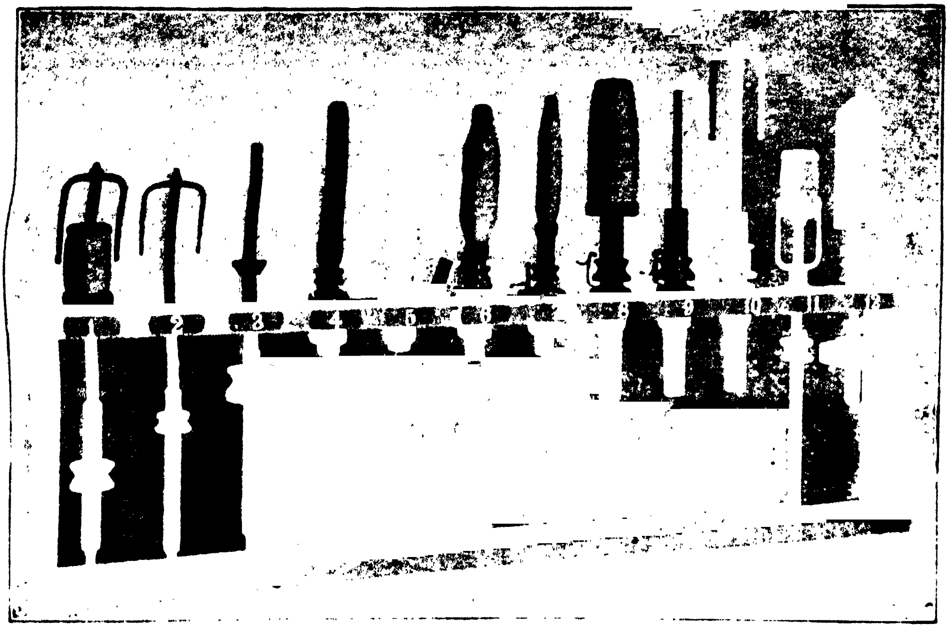
92. WEFT YARN SPUN

Spinning Cotton. It is very seldom that a cotton spinner meets with a throstle frame of the old model, and Danforth's cap frame has never obtained a strong footing in cotton mills. The honours are divided between the ring traveller and the mule. For the rapid, cheap production of low counts, the ring frame has no equal. In working with the traveller, it is important to note that the weight of the ring is exactly proportioned to the work. If too heavy, it breaks the yarn, which is unable to drag it round; if too light, the yarn will not be twisted, and the delivery is sure to be faulty. Oiling and cleanliness are specially to be attended to, for it is obvious that the least obstacle to a ring travelling at such a speed would be attended with serious results, and the constant friction would quickly heat both ring and traveller to fusing point.

Draft is a subject of general interest; but it is on the mule its most delicate issues are tried. To spin a thread which will give eighty six miles to the pound calls for fine adjustment of the means, and this is what is done when we produce a 180 count [**92**] There are even higher counts,



93. YARN FROM RING SPINNING FRAME



94. VARIOUS SPINDLES (Brooks & Doxey, Ltd., West Gorton, Manchester)
1. Flyer doubling spindle 2. Flyer spinning spindle 3. Plain ring doubling spindle 4. Self-contained ring spindle 5. "Mayor" ring spindle 6. "Union" gravity twist ring spindle 7. "Union" gravity weft ring spindle 8. "Ferguslie" ring doubling spindle 9. "Union" gravity ring doubling spindle 10. "Union" gravity flyer spinning or doubling spindle 11. Inverted flyer doubling spindle 12. Cap spindle

but these are generally produced by the hand mule and exceptionally skilled workers. We have seen the manner in which draft is put upon rollers, but the stretch of the mule carriage brings in another factor. You can use the carriage to attenuate the thread by simply making it run more quickly than the rollers deliver. In cottons of short staple this is risky; but with long-stapled cottons the practice is good, because by that means a fine twist is put on the threads, and all the soft parts are fully drawn, so that the final twist reduces the whole length to uniformity.

Spinning Wool. Woollen thread is taken directly from the condenser to the mule. But the action of this mule is quite different from the cotton mule. In the first place, there is only one set of drawing rollers on the woollen mule—one fluted roller paired with a heavy top roller—the chief use of which is to hold the yarn for the draft of the carriage. This brings out the second difference. The spindle carriage moves out, drawing the threads from the rollers, and when about half-way on its course the delivery ceases. Our carriage goes on its way, twisting and drawing out the yarn. At the end of the traverse or stretch the carriage stops, but the spindles continue to revolve, twisting up the thread. By a curious motion the yarn is let out for a few inches, to avoid hardening and breaking the thread. Now the spindles reverse, and the faller wires come into play, lifting off the loose threads from the head of the cop, and stenting the thread for the next act. The spindles stop, reverse, and then the carriage moves rapidly inwards, winding on the spindles the spun yarn.

Worsted. In worsted spinning any one of the three frames—the flyer, the cap, or the ring traveller—may be used. The latter has not come much into use, though some very tempting machines of that model are on the market. The throstle flyer is the favourite for general work, and specially for long-stapled wools. Only one thing is to be noted in worsted, as distinct from the general use of the flyer and spindle, and that is the amount of twist required. The flyer must be carefully adjusted by the change pinion, so that the required amount of turns may be given.

Spun Silk. Here we have a use for the old fashioned throstle. The silk drawings are mounted on the creel of the throstle frame, and passed through drawing rollers and flyer on to the bobbin. Driven by a motion of its own, the bobbin pulls the thread round it, while the lifter plate and flyer regulate the delivery. No simpler, more direct method of spinning has been invented, and this strong staple suits it very well.

Linen Yarns. In linen manufacture we use the throstle spinning-frame, but with improvements and modifications which require special notice. Flax is a strong fibre, and in some ways rather intractable. An objection to the throstle by the cotton spinner is that it demands too much from the half-spun thread. A slender fibre like cotton could not be expected to carry round a bobbin and wind itself upon it by mere drag.

The difficulty with flax is all the other way. As the bobbins fill they develop a force of their own, and would soon overrun the supply of thread if nothing were done to prevent it. To meet this, a spring self-acting apparatus has been devised.

Along the traverse rail lies a long rod, with little steel springs attached, which apply a gentle and graduated pressure to the growing bobbins and keep them moving at a steady rate. The degree **of pressure is very simply adjusted** by means of **the worm and ratchet wheel** at the end of the machine.

Closely associated with this, and called into existence by the same cause, is the hot water trough. This trough sits in the middle of the machine, just below the creel on which the rovings are fixed. By the hot water the gummy substance of the flax is softened, and the fibre made amenable to spinning. From the trough the roving passes into the grip of the retaining rollers, the lower one brass and fluted, and the upper wood covered with felt or leather. Across the space known as the *reach* the threads are carried in between the drawing rollers, the speed of which is as much greater than the retaining rollers as the draft requires. When it has issued from the drawing rollers the thread begins to twist from the action of the flyers working on the spindles below the thread plate. Through the eye of the plate it is taken to the flyer, and on to the bobbin. It should, perhaps, be admitted that the patent self-acting drag of which we spoke has not come into universal use. The older method of dragging the bobbins by means of drag bands held against the bases of the bobbins by means of weights is still used. When the pressure has to be increased the spinner moves the weight a peg further away from the point of contact, and by widening the distance increases the leverage. The doffers, when the bobbins are filled, remove the flyers, break the threads, put on fresh bobbins, and the frame starts again.

Rope Yarns. The rope manufacturer has **taken most of his machinery from the flax spinner; but he has made his own use of the appliances. It is very seldom you will find wet spinning in a rope factory.** The softening of the **fibres reduces their strength, and strength is the quality most desired in ropes. When water is resorted to, it is cold, and therefore does not melt the gum of the fibre to an injurious extent. For a long time the rope spinner was allowed to pick up his machinery where he would; but now the machinists have taken to considering his wants seriously.** The consequence is that we have a **good many machines** on the market which have not stood the test for long use. As a rule, rope yarns are spun on horizontal spinning frames **[95]**. These frames have not yet been studied by us. Drawing rollers and spindle, with flyers, are all on one level. No new principle is involved, however, the chief recommendation of the horizontal form being the wider distribution of the weight of the frame.

Jute Spinning. The jute spinner uses a throstle spinning-frame, which is more elaborately mounted than any other textile spinner. The frame is of vast size, with bobbins, flyers, and rollers in proportion. The roving winds off the bobbin set on the creel on the head of the machine, and passes through the guide eye to the first pair of rollers, in through the binder plate, over the curved conductor plate, in between the drawing rollers, on through the thread plate, twining round the flyer leg, and on to the bobbin. As this is the only spinning frame proper of the jute worker, he must make the most of it, and it is no uncommon thing for a draft of 7 to 1 to be put on. Drawing out a thread with about one twist to the inch, and already drawn out to considerable tenuity, to such a length, involves some risk. For that reason we have a continuous succession of supports to the thread. The binder plate and conductor plate, before the drawing rollers, and the thread plate after, are necessary to support the yarn till it gets its final and strengthening twist from the flyer.

STRESSES IN ROOF TRUSSES

Timber Trusses, Iron and Steel Trusses for Various Spans, Curved Trusses, Effect of Wind

By Professor HENRY ADAMS

Collar Beam Truss. This truss [187], although the simplest from a constructive point of view, is by no means simple when the stresses are considered. The legs of the truss tend to spread with the weight of the covering, and the part of the principal rafters below the collar is in the condition of a lever, so that if the walls are not rigid, a bending moment is produced at the junction with the collar. Modifications of this form are frequently used for the open roofs of churches, and the walls are only prevented from being thrust outwards by their dwarf height and the buttresses placed against them opposite to each truss. When the walls are higher, the overturning effort is greater, and many cases have occurred of the walls being actually thrust out. Under such conditions the collar beam is in full tension, but any intermediate condition may occur between this and full compression owing to rigid walls. It is this uncertainty of condition that creates the chief difficulty of estimating the stresses, but when allowance has to be made for the wind blowing on one side the difficulty is further increased. The frame and stress diagrams for vertical loading and rigid walls are shown in **188** and **189**, and for vertical loading and yielding walls in **190** and **191**. In **190** the bending moment diagram due to the leverage of the ends will be observed on the upper sides of the principal rafters. The dotted lines are virtual force lines to replace the bending moment diagram, and allow the complete stress diagram to be drawn.

King Post Truss. The king post truss [**192**] is the most common form for wooden roofs from 28 to 30 ft. span. The frame and stress diagrams with the wind on one side are shown in **193** and **194**. Upon a superficial view of **192** it appears as if the roof were supported by the king post standing on the tie beam, but the reverse is the case, as the tie beam is held up to the foot of the king post by an iron stirrup.

Composite Roofs. Composite roofs are formed of a combination of wood and iron, the compression members being of wood and the tension members of iron, which from its great tensile strength is more suitable, but these roofs are not very frequently adopted.

Queen Post Truss. The queen post truss [**195**] is a convenient form for wooden roofs of 30 to 45 ft. span. Under irregular loading, such as is produced by the wind acting upon one side, it is a deformable structure, owing to the want of cross bracing in the central space. Bending moments are caused in the tie beam, but its stiffness prevents the roof from suffering much actual change of shape. The frame diagram is shown in **196** and the stress diagram in **197**. As the latter involves some difficulty of construction, a full description will be given. First set down the load line 1 to 8 of stress diagram, join the extremities, which will give the direction of the reactions and substituted forces 1-11-10-9-8 on frame diagram without fixing the amounts. From point 2 draw an indefinite line parallel with 2-12 on frame diagram, and fix the position of point 27 upon it by a line from point 7 parallel to 7-17, then 17-9, being horizontal, will fix the position of point 9, thus obtaining the right-hand reaction. Next draw 4-15 and 5-15, giving point 15, and as points 15, 14, and 10 are all separated by parallel lines, the points will be on a straight line passing through point 15. This fixes the position of point 10, and at the same time the amount of substituted force 10-9, and as the substituted force farthest from the wind is equal to half the amount of the substituted force nearest to windward side, it will be seen that point 11 will be central between points 9 and 10. The remainder of the stress diagram presents no further difficulties, and after completion may be tested for accuracy by drawing a funicular polygon on the frame diagram as shown by stroke and dot lines, which will be found to close. The following tables of scantlings will be found suitable for ordinary cases, and will obviate the necessity for making calculations.

SCANTLING FOR KING POST TRUSSES

Baltic fir. 10 ft. apart. Pitch, 25° to 30°. Slate

Span Feet	Thickness of Truss and all Members	Breadth on Elevation				Purlins	C. R.
		Tie Beam	King Post	Struts	Principal Rafters		
20	4	8	3	2	4	8 × 4	3½
22	4½	9	3¼	2¼	4	8 × 4	4
24	5	10	3½	2½	4	8 × 4½	4
26	5½	11	4	2¾	4	9 × 4¾	4½
28	6	12	4	3	4	9 × 5	4½
30	6½	13	4½	3¼	4½	9 × 6	5

Head and foot of king post twice width of middle. Reduce the thickness of truss by ½ in. and the depth of tie beam by 1 in. if there is no ceiling.

Wrought-iron and Steel Roofs. Omitting a few cast-iron ribbed roofs, it may be said that all metal roofs were formerly of wrought iron, but the greater tenacity of mild steel and its extensive manufacture render it *the* material of the present day. The same types of construction are used, the difference being only in the lighter sections employed. The arrangement of the trussing of all roofs varies primarily with the span; the roof covering is supported usually by "common rafters," and, in order that these may

Span Feet	Thickness of Truss and all Members	Breadth on Elevation.					Purlins.	Common Rafters.
		Tie Beam.	Queen Post.	Struts	Principal Rafters.	Straining Beam.		
32	4	9	4	2	4½	6	8 × 4	3½ × 2
34	4½	10	4	2	5	6½	8 × 4	4 × 2
36	5	10½	4½	2	5½	7	8 × 4½	4 × 2
38	5½	11	4½	2	5½	7½	8 × 4½	4 × 2
40	5½	11½	5	2½	6	8	9 × 4½	4½ × 2
42	6	12	5	2½	6	8	9 × 4½	4½ × 2
44	6	12½	5½	2½	6½	8½	9 × 5	4½ × 2
46	6	13	6	2½	7	9	9 × 6	5 × 2

have economical dimensions, the purlins that carry them require to be within certain limits of spacing, say 5 to 10 ft. apart. This spacing fixes the position of the supports to the principal rafters, and therefore the number of bays into which they are divided. The distance apart of the trusses is partly determined by the strength of suitable purlins and partly by the desirability of securing a sufficient load upon each truss to obtain convenient and economical sections of the various members. Owing to the necessity of providing against the effects of corrosion, no bar or plate may be less than ¼ in. thick or ½ in. diameter, and where the load is very light, some material may be practically wasted from this cause. The external pitch of a roof is fixed by the nature of the covering and climatic or æsthetic conditions; the under side may be varied by giving more or less camber to the tie rods at pleasure, and this affords another means of adjusting the stresses in the members to an economical value, the stresses being increased as the camber is greater owing to the reduction of the central depth.

Number of Bays for Given Spans. The following table gives the average practice for iron and steel roofs, but so many points have to be considered in designing roofs that no precise rule can be laid down.

1 bay in rafter is suitable for roofs up to 15 ft. span.

2 bays in rafter are suitable for roofs 15 to 30 ft. span.

3 bays in rafter are suitable for roofs 25 to 50 ft. span.

4 bays in rafter are suitable for roofs 40 to 75 ft. span.

5 bays in rafter are suitable for roofs 60 to 100 ft. span.

Iron roofs to cover a large area are generally cheaper when the number of separate roofs is reduced and the trusses increased in span up to a maximum of 60 ft., owing to the more accurate proportioning of the material to the stress and the saving of supports.

Types of Construction for Various Spans. Typical arrangements of trusses with the principal rafters divided into one to four bays are shown in outline in **198** to **205**. With the exception of **205**, these involve no difficulty in determining the stress diagram and resultant stresses so that they need not be dealt with further; but the one referred to, known as a Fink, French, or Belgian truss or compound trussed rafter roof will well repay a more detailed investigation.

Fink Truss. Having drawn the frame diagram and marked on the external loads, set down the load line of stress diagram [**206**], join the extremities, and proceed with the diagram in the usual manner until point 14 is reached, when it will be found that point 15 cannot be obtained as only one of the surrounding spaces is known—*viz.*, 14, and it is at this point that the method of *substituted members* will have to be resorted to, in order to find point 18. For the members 15, 16, 17 on frame diagram substitute the member *a*-*b*, as shown for clearness on separate sketch [**207**], then, turning again to the stress diagram, draw 14-*a*, 4-*a*, giving point *a*; *a*-*b*, 5-*b*, giving point *b*; and *b*-18, 11-18, obtaining point 18. The remainder of the diagram may now be added without further difficulty.

Curved Trusses. A crescent or sickle-shaped truss is sometimes used for large roofs, as in the case of the Charing Cross, Cannon Street, and Fenchurch Street railway-stations in London. In such cases it is necessary to provide cross bracing to allow for the effect of the wind on one side or the other, so that whichever side it blows from one member of the cross bracing in each bay will take the whole of the load as a tensile stress. The Charing Cross truss is shown in **208**.

Effect of Wind. It is not an easy matter to measure the velocity of the wind, and it is still more difficult to estimate its force against a plane surface in any position. Although consideration has been given to the subject for more than a hundred years there is still a need for practical investigation upon a large scale. It may, however, be assumed that in ordinary positions a pressure of 28 lb. (¼ cwt.) per square foot is very rarely exceeded, and that in the most exposed positions an allowance of 56 lb. (½ cwt.) per square foot will cover all contingencies. The larger the area taken into account at one time the lower the pressure is likely to be. It does not always blow horizontally, and when there are many buildings in the neighbourhood it may be deflected downwards upon any given roof. Assuming the wind to blow horizontally with a force of 42 lb. per square foot against a roof of 30 degrees pitch the effect normal to the roof plane [**209**] will be reduced to $p \sin \theta = 42 \times \sin 30° = 21$ lb. In the same way, if the wind be assumed to blow horizontally with a force of 56 lb. per square foot the normal pressure will be reduced to 28 lb. Authorities are, however, not agreed as to the true normal pressure, some take it as the $p \sin \theta$, others $p \sin^2\theta$, and still others as $p \sin \theta^{1\cdot84 \cos \theta - 1}$. These values are contrasted in the curves shown in **210**

NINETEENTH CENTURY PROSE

2.—Being a Brief Review of the Essayists, Historians, and Philosophers, from William Cobbett to Thomas Carlyle

By J. A. HAMMERTON

The Characteristics of Cobbett. WILLIAM COBBETT (b. 1762; d. 1835) started life by scaring crows, but left a name which will be remembered with those of the most famous writers of his own time. He may be said to personify the whole art of self-education. By self-denial and perseverance he acquired a vast sum of varied knowledge, and wielded immense influence as a politician and a journalist, inspiring his countrymen with a reasoned love of their native land. Despite extraordinary difficulties, he learnt English and French so well as to be able to write grammars in both languages, and developed a literary style as natural as Defoe's, as vigorous as Swift's, brightened by humour and telling invective, and perhaps as characteristically Saxon as any that could be named. He was a clean-living man, who delighted in the open air, being a born student and lover of Mother Earth. Above all, Cobbett saw clearly, thought clearly, and uttered clearly. His varied career from plough to Parliament will well repay study. The works he left are as diversified as was his life.

Cobbett's "English Grammar" and "French Grammar" are written in the form of letters to his son, and are unsurpassed in the lucidity of their arrangement and their quality of genuine liveliness. We could wish that everyone read the former. Despite its unattractive title, it may be commended as vastly entertaining as well as instructive. His "Weekly Political Register," started in 1802, was continued, apart from one small break, until his death; it was for two years edited from prison, where he was sent for his strictures on flogging in the Army; and for a time from America, whither he fled to escape from further imprisonment. In 1803 he began the "Parliamentary Debates," whence originated our present "Hansard." He wrote a "History of the Reformation," which is still read, though chiefly by Roman Catholics; but his "Advice to Young Men" is full of practical common-sense for all. Every young man should read it, and young women also. Its vigour and frankness are as refreshing as the breath of the sea. His best work is to be found in the picturesque accounts of his political tours on horseback, which are familiar as "Cobbett's Rural Rides," and the student in search of a guide to muscular English would do better to read a chapter from this each day than from almost any other prose work. Of his faults, his egotism has counted too much to his detriment. That it was a reasoned egotism may be seen in a brief passage from the "Rural Rides."

A Specimen of Cobbett's Style. The writer remarks on the beneficial effects of early rising on the traveller, abstinence from wine and spirits, and moderation in eating, and on the fact that, under conditions specified, the riding of twenty miles was not so fatiguing at the end of a tour as the riding of ten miles was at the beginning of it. He goes on to say:

"Some ill-natured fools call this egotism. Why is it egotism? Getting upon a good strong horse, and riding about the country . . . requires neither talents nor virtues of any sort; but health is a very valuable thing; and, when a man has had the experience which I have had, in this instance, it is his duty to state to the world, and to his own countrymen and neighbours in particular, the happy effects of early rising, sobriety, abstinence, and a resolution to be active. It is his duty to do this; and it becomes imperatively his duty when he has seen, in the course of his life, so many men, so many men of excellent hearts and of good talents, rendered prematurely old, cut off ten or twenty years before their time, by a want of that early rising, sobriety, abstinence, and activity, from which he himself has derived so much benefit, and such inexpressible pleasure . . . It is seldom that rain, come when it would, has prevented me from performing the day's journey that I had laid out beforehand. And this is a very good rule: stick to your intention, whether it be attended by inconveniences or not; to look upon yourself as bound to do it."

Here we have Cobbett the man; no dreamy theorist, but a master of hard facts and a master who is compelled to convey his knowledge in a manner which none can misunderstand. Cobbett is not a great literary character; but his style is the best of models for all who aspire to write clearly and correctly, and he occupies by right a definite place in the pages of the SELF-EDUCATOR.

Anecdotes and the Minor Morals. ISAAC D'ISRAELI (b. 1766; d. 1848), the father of Lord Beaconsfield, wrote a number of anecdotal works which, though somewhat slipshod, offer evidence of much culture and wide reading, being chiefly notable for the entertainment they afford and the stimulus they give to further inquiry in the by-paths of literary history. The "Curiosities of Literature" is the best of these; its companions are "Calamities and Quarrels of Authors," "Amenities of Literature," and "The Literary Character." JOHN FOSTER (b. 1770; d. 1843), a Baptist minister, was the author of a series of "Essays," one of which, that "On Decision of Character," should be read with Cobbett's "Advice to Young Men"; the "Self-Culture" of JOHN STUART BLACKIE (b. 1809; d. 1895); and the "Self-Help" of SAMUEL SMILES (b. 1812; d. 1904).

Landor's "[illegible] Conversations." Walter Savage Landor (b. 1775; d. 1864) was an author who, as Mr. Birrell says, "preferred stately [illegible] to chatty familiarity." He lived, in a sense, alone, and his work is also independent. Writing poetry for "amusement" and prose as "business," his "Imaginary Conversations" possess strong dramatic qualities which have caused many to wonder that their author failed to write a great play. Describing these "Conversations," the late H. J. Nicoll, in a brilliant passage of summary writing, says that they "are full of fine thought, expressed in a style so finished, so eloquent, so clearly bearing the impress of genius and cultivated taste, so felicitous in imagery and diction, that one wonders why they are in general so little read. The reason probably is that their subjects have little interest to people in general, and that their tone of sentiment does not, for the most part, appeal to the ordinary sympathies and emotions of humanity." The "Conversations" were published between 1824 and 1853; they range over a vast area of topics, and are 125 in number. In these lofty and earnest pages we are, says the "Edinburgh Review" of 1846, by turns, "in the high and goodly company of wits and men of letters; of churchmen, lawyers, and statesmen; of party-men, soldiers, and kings; of the most tender, delicate, and noble women; and of figures that seem this instant to have left for us the Agora [Greek equivalent of the Roman Forum] or the schools of Athens, the Forum, or the Senate of Rome. At one moment we have politicians discussing the deepest questions of state; at another, philosophers still more largely philosophising; poets talking of poetry; men of the world of worldy matters; Italians and French of their respective literatures and manners." Landor, in fine, is our English Lucian: that classic writer of dialogues who flourished in Greece during the second century. Among Landor's dialogues especially admired for their dramatic intensity are those between Peter the Great and Alexis, and Henry VIII. and Anne Boleyn. "I shall dine late," said Landor, in an oft-quoted phrase; "but the dining-room will be well-lighted, the guests few and select." Yet we may all some time or other "dine" with Landor as our host and be assured of excellent entertainment. When one is studying the life of Shakespeare, Landor's "Examination of William Shakespeare" may be read as a charming piece of imaginative prose.

Some Lesser Litterateurs. William Hone (b. 1780; d. 1842) was a sort of minor Cobbett, with something of D'Israeli's feeling for letters. His "Every-Day Book," "Table-Book," and "Year-Book" bear tribute to his industrious study of old manners and customs. The first-named contains a tenderly-worded dedication to Charles Lamb, and to the "Table-Book" the "gentle Elia" contributed his selections from the Garrick Plays. But Hone's books are chiefly valuable as works of reference to the literary man. The "Papers" of John Wilson Croker (b. 1780; d. 1857) and Thomas Creevey (b. 1768; d. 1838) supply much intimate detail of the Court, literary, and political life of their time, the one from a Tory and the other from a Whig point of view. Croker, who is much better known, Creevey having been a "discovery" of Sir Herbert Maxwell in 1903, was a frequent contributor to the "Quarterly Review." His chief work was an edition of Boswell which drew forth a remarkably bitter criticism from Macaulay, and he also began an edition of Pope which was completed in our own time by Whitwell Elwin (b. 1816; d. 1900) and Dr. W. J. Courthope (b. 1842).

Leigh Hunt. James Henry Leigh Hunt (b. 1784; d. 1859) was an essayist of considerable charm and versatility, whose friendships secure for him a greater meed of recognition than his writings, though these are not unimportant. He introduced Shelley and Keats to one another, and brought these poets before the public in the "Examiner," of which he was editor and part proprietor. The student of English literature will find much profit in his "Imagination and Fancy," "Wit and Humour," and "Men, Women, and Books." His "Dante's Divine Comedy: The Book and its Story" is also of value, while his "Autobiography" contains enough to secure for it the permanent interest of all bookmen. London and "The Cockney School" found in him an energetic champion, and his gossipy volume on "The Town: Its Remarkable Characters and Events" retains a certain measure of popularity. As a critic he was appreciative; and his method of handling such themes as old age and child life easily secures for him the affection of sympathetic readers. He had another link with Charles Lamb: he stammered. It was only in part—and that part a small one where his real worth is concerned—that he can be associated with Charles Dickens's satirical portraiture of Harold Skimpole in "Bleak House."

Nassau William Senior (b. 1790; d. 1864) was an acute literary critic as well as a political economist. His "Essays on Fiction," articles on Scott, Lytton, Thackeray, and others, contributed to the "Quarterly," "Edinburgh," and other reviews, were published in collected form in 1864, and will well bear perusal by the student. William Maginn (b. 1793; d. 1842), scholar, critic, humorist, was once a great force in the magazine world. He remains, despite all his great gifts, a "might-have-been," the original of the Charlie Shandon in Thackeray's "Pendennis." He was one of "Blackwood's" most brilliant contributors, and as the conductor of "Fraser's Magazine" he gathered round him some of the choicest and most distinguished of contemporary writers. Anna Brownell Jameson (b. 1794; d. 1860) wrote a volume on "The Characteristics of Shakespeare's Women," which is still a favourite.

A Short Study of Carlyle. Thomas Carlyle (b. 1795; d. 1881) began his literary career as a writer in the "Edinburgh Encyclopædia," for which, between 1820 and 1823, he wrote articles on Lady Mary Wortley Montagu, Montaigne, Montesquieu, Dr. John Moore, Sir John Moore, Necker, Nelson, Mungo Park, Lord Chatham, William Pitt, and several papers of a topographical character. Only one of these—the paper on Sir John Moore—can be described as inadequate. From the first Carlyle seldom spared himself. In 1824 he published two translations—one from the French (Legendre's "Geometry"), and one from the German (Goethe's "Wilhelm Meister"). The latter work, praised by "Blackwood's" and the "Edinburgh," was attacked by De Quincey in the "London Magazine," to which Carlyle had been contributing his "Life of Schiller." The last chapters of the "Life of Schiller" appeared simultaneously with the unjustifiable attack. Whatever pain may have been caused by De Quincey was more than assuaged by the commendation from Goethe, who wrote a eulogistic introduction to a translation of the Schiller volume which was published at Frankfort in 1830, three years after Carlyle's period of apprenticeship may be said to have been brought to a close with his studies of "German Romance." Meanwhile Carlyle had met Jeffrey and become a contributor to the "Edinburgh Review," his connection with which lasted for seventeen years.

Carlyle's Literary Style. One of the real curiosities of literature is the distinction between the form of Carlyle's early writings and that known as "Carlylese," the undoubtedly powerful, but electrical, explosive, ejaculatory style whose beginning may be noted in his "Sartor Resartus," a work of autobiographical as well as of philosophical interest, which, originally published in "Fraser's," first won adequate recognition in America. The student who would read Carlyle aright can do no better than begin by digesting Professor Nichol's masterly monograph in the "English Men of Letters" series; Froude's contentious pages should be left for a later period. Carlyle's greatest works are those in history, sociology, and politics. But there is a great deal in his miscellaneous essays—those on Burns, Johnson, Scott, Voltaire, Diderot, and Mirabeau, for example—that must not be overlooked by any reader who desires to understand the man himself. Carlyle has been greatly misunderstood; but his influence has been almost incalculable in Germany as well as in England. He was "human, like ourselves"; more, perhaps, of an iconoclast and a prophet than a constructive power; but he looked to the "foundations of society," he had a genuine love of truth, and his striving after truth has left to posterity a standard of thought which must remain a permanent social as well as literary force.

The Influence of Carlyle. Essentially masculine in view, Carlyle has yet had a marked influence on women readers. The Swift of the nineteenth century, many a Stella has been his pupil. Appreciations—and depreciations—of his labours there are in abundance, but perhaps Walt Whitman in his "Specimen Days" touched the reality as closely as anyone. "As a representative author, a literary figure," he wrote, "no man else will bequeath to the future more significant hints of our stormy era, its fierce paradoxes, its din, and its struggling periods than Carlyle. He belongs to our own branch of the stock, too; neither Latin nor Greek, but altogether Gothic. Rugged, mountainous, volcanic, he was himself more a French Revolution than any of his volumes . . . As launching into the self-complacent atmosphere of our days a rasping, questioning, dislocating agitation and shock, is Carlyle's final value." Carlyle began life, in a sense, by teaching mathematics in a Fifeshire school; he remained a teacher to the end of the chapter. As a stylist he is the greatest "free lance" in the language; but the reader should beware lest he impute to the leader the sins of his would-be followers, as many a one has sought to thunder in Carlylian strain with the most unhappy results. Where Carlyle's style is concerned we must not judge him by the standard of any other writer; he claims by right to be judged by the vivid (and vivifying) result. Of no great writer could it be said with more cogency that "the style is the man." His view of the literary calling is indicated in his lecture on "The Hero as Man of Letters," where he writes:

Carlyle on the Man of Letters. "On the whole, one is weary of hearing about the omnipotence of money. . . . There ought to be Literary Men poor. . . . Who will say that a Johnson is not perhaps the better for being poor? It is needful for him, at all rates, to know that outward profit, that success of any kind is *not* the goal he has to aim at. Pride, vanity, ill-conditioned egoism of all sorts, are bred in his heart, as in every heart; need, above all, to be cast-out of his heart,—to be, with whatever pangs, torn-out of it, cast-forth from it, as a thing worthless. Byron, born rich and noble, made-out even less than Burns, poor and plebeian. Who knows but, in that same 'best possible organisation' as yet far off, Poverty may still enter as an important element? What if our Men of Letters, men setting-up to be Spiritual Heroes, were still *then*, as they now are, a kind of 'involuntary monastic order'; bound still to this same ugly Poverty,—till they had tried what was in it too, till they had learned to make it to do for them! Money, in truth, can do much, but it cannot do all. We must know the province of it and confine it there; and even spurn it back, when it wishes to get farther."

We cannot well in a few words arrive at any plan for the especial study of Carlyle. From the wide range of his writings the general reader will take to such works as his fancy prompts, the student to those his studies suggest, and both may be left safely to come under the all-compelling influence of this mighty and original thinker. The least that should be known of Carlyle's works are "The French Revolution," "Sartor Resartus," "Heroes and Hero Worship," and "The Life of John Sterling." If one begins with "Heroes and Hero Worship," the appetite is more likely to be whetted than by entering the Carlyle treasure-house through the gate of "The French Revolution."

PATTERN CONSTRUCTION & MOULDING

The Materials and Tools for Patterns. Pattern Making. Moulding Tools and Practice. Bedding-in. Turning over. Sweeping

continued from page [illegible]

By JOSEPH G. HORNER

We are now in a position to consider first the methods of pattern construction, and then the broad systems of moulding adopted.

The Pattern. The pattern must be considered from two principal points of view—that of its method of construction and maintenance of form (matters which it has in common with wood-working generally), and that of its moulding, or facility for delivery from the sand. It is the last named which separates pattern-making as a trade from carpentry and joinery.

The Materials. It is obvious that maintenance of form may be secured in one of two ways, either by employing a non-perishable material, or by adopting those strong methods of construction which are practised in the wood-working trades generally. Both are employed in pattern-making. Articles of small and moderate dimensions, from which hundreds or thousands of moulds have to be taken, are made in metal, while others—namely, those of large dimensions, and those of any sizes from which comparatively few castings are required—are constructed in wood. These last include by far the largest number.

Timber. Then, as there are different kinds of timber, some stronger and more durable, some less given to warp and shrink than others, selection is made from several sorts to suit different classes of patterns. Yellow pine and mahogany are chiefly used. Other woods are occasionally employed, but not to any considerable extent. Yellow pine is suitable for large patterns, mahogany for those of small size. Both woods must, of course, be well seasoned, and the straighter the grain and sounder the stuff the better. The choice of yellow pine as the principal material for pattern-making might seem to be objectionable on account of its softness and openness of grain, as being ill-adapted to stand the rough usage of the foundry and to resist the action of the moisture in the foundry sand.

But in patterns properly constructed these objections have little reality in fact, for they are protected from excessively rough usage by the insertion of rapping and lifting plates, and the porous grain is protected with varnish or paint. And, on the other hand, these possible evils are much more than counterbalanced by the advantages of moderate price, straightness of grain, workability, and fair capacity for resistance to heat and moisture. And, further, many patterns are moulded from only once, or a few times, and for these pine is amply good enough. For patterns which are to have a very large number of mouldings, and of not excessive dimensions, there is always the harder but more costly mahogany available.

Tools. Being a wood-working trade, the tools used are nearly identical with those employed by carpenters, joiners and others. The principal ones will be found illustrated in the series devoted to Carpentry and Joinery, while underlying principles of their design are treated in the series on Tools, so that only a bare list of pattern-makers' tools need be offered here. They are the following:

SAWS. Hand, tenon, dovetail, bow, compass, and keyhole.

PLANES. Jack, trying, smoothing, rebates, and rounds

CHISELS. Paring, 1½, 1¼, 1, ¾, ½, ¼ in.; firmer, 1½, 1, ¾, ½, ¼ in.

GOUGES. Paring, flat, 1½, 1, ¾ in.; middle-flat, 1¼, ¾ in.; quick, 1¼, 1, ¾, ½, ¼ in.; firmer, 1½, 1¼, 1, ¾, ½, ¼, ⅛ in., to which may be added a few bent gouges for core-box work.

TURNING TOOLS. Gouges, ¾, ½, ¼ in., chisels, ¼, ¾, ½ in.; side tools, right and left handed, ¾, ½ in.; round noses, ¾, ½, ¼ in.

BORING TOOLS. Brace and set of bits, half-dozen gimlets, half-dozen bradawls.

MEASURING TOOLS. 2 ft. standard rule, 2 ft. iron contraction rule, 12 in. try-square, 4½ in. try-square, two set squares, bevel, two pairs of trammels, large and small; wing compasses and spring dividers, two small marking gauges, and a panel gauge. Two pairs of callipers, one inside, one outside.

MISCELLANEOUS TOOLS. Hammers, light and heavy; wooden mallet, two screwdrivers (one large, one small), drawknife, axe, spokeshave, hone, two gouge slips. A somewhat smaller selection will suffice for a beginning. Many workmen will double the number. This is only a representative selection, and no more.

Machine Tools. The machine tools used in pattern shops embrace lathes, circular and band saws, planing machine, trimmers, and sometimes a special apparatus for the setting and sharpening of circular and band saws. So much of economical working necessarily depends on the employment of the machines that even in small shops employing only half-a-dozen hands these should find a place. There should be even in these two or three lathes, ranging in dimensions from 5 in. to 10 in. centres, one of which should properly be a face lathe, also a circular saw, either of the common type, or of the dimension kind, the latter being preferable where one saw-table only is used, a band-saw of light construction, with wheels of not less than 2 ft. 6 in. diameter, the width of saws to range from ⅜ in. to 1 in., and one planing machine, being either a surfacing machine or a thicknessing machine, or both in combination. All these machines should be under the charge of one man, as increased efficiency is thereby obtained.

The Pattern: Its Permanence of Form. There are five principal methods by which permanence of form is secured in patterns,—open joints, boxing-up, halving, lagging-up, and segmental construction, each one being adopted in different classes of work, and two or more often being combined in one piece. Their necessity is due to the treatment to which patterns are subject, of moisture in the sand, and of dryness out of the sand and in the stores.

Open Joints. These fill a valuable place in pattern work. The necessity for their use occurs in wide pieces. If, for instance, a piece of board be 6 in. or 8 in. wide it cannot shrink or expand much under changeful hygrometric conditions. But if, say, 18 in. wide, or if a broad pattern of 3 ft. or 4 ft. in width be glued up like a table-top, its width will be constantly changing, according as it is in or out of the sand. These changes are minimised by using narrow strips with joints open to the extent of $\frac{1}{16}$ in. or ⅛ in., in which space the movements of the boards are localised. Fig. 53 shows a broad plating with open joints. The separate pieces are often dowelled, and they are retained flat by the other parts of the pattern on which they are fastened.

Boxing-up. This is preferable to making large patterns of solid timber, for three reasons—first, because shrinkage is lessened; secondly, because timber is economised; and thirdly, because the weight is reduced. Patterns are boxed up by nailing or screwing top and bottom sides to cross bars [53 and 54]. There is a right and a wrong way of doing this. The right way is to carry the sides up, as in 53 and 54. The wrong way is to bring top and bottom right across, as in 55. The reason for this difference is that when the top or bottom shrink or swell they cause overlaps, which tear the sand up.

In wide, boxed-up patterns, the top and bottom are made with open joints [53].

Halvings. Halvings [56] fill a large place in pattern work, as they do in carpentry. But they are employed more frequently in the former trade, being adopted in most cases where tenoned and mortised joints would be made by the carpenter and joiner. They are more easily cut, and are substantially as serviceable for patterns, besides which they have the very great advantage of permitting subsequent alterations in patterns, which fill a large economical place in the trade.

Halvings are adopted when framings have to be constructed for which the crude device of cutting out of solid board would involve short grain. A single example of a halved frame, typical of hundreds of variations in outline, is given in 56. With the halving a dovetailed form is frequently combined (A) to prevent all risk of the joints opening.

Lagging-up. This is adopted in cylindrical pieces, as pipes, columns, and engine cylinders, when the diameter exceeds 4 in. or 5 in. The "lags" [57] are narrow strips laid round on cross bars and glued thereon, and also by their adjacent edges. The object is the same as in the preceding examples—namely, to localise and lessen the change of form. Solid stuff would curve on the joint faces [58], with loss of the truly circular form, while in a lagged-up pattern changes due to desiccation and moisture are localised. How this method is embodied in a pattern column is shown in 59, which represents such a half pattern laid open in the joint face, with the cross bars to which the lags are attached. Methods of fitting flanges, end core prints, and mouldings are also indicated.

Segmental Construction. This is an exceedingly important detail of pattern-work, being adopted for nearly all patterns of sweeped and annular form, such as curved portions generally, and for the rims of wheels and pulleys of all dimensions. In principle it is paralleled by the disposition of bricks in a wall, in superimposed layers, with end joints alternating. The segments are sawn out, jointed, glued in layers, and frequently strengthened by the insertion of wooden pegs. The latter would not be employed but for the fact that the rough usage to which patterns are subjected in the foundry and the moisture of the sand are in time liable to overcome the adherence of the glue alone.

Example of Segmental Work. A typical example of segmental work is that afforded by the ring [60], for any common wheel. It is easy to see what would happen if such a ring as this were made of solid wood. However hard, close grained, and well seasoned it might be, it would not only become elliptical by the alternate wetting and drying to which it is subjected in the foundry, but the short grain would snap, and the pattern be falling to pieces before half a dozen moulds had been made from it. But being built up, there is no tendency to depart from the circular form; the only shrinkage which can take place being of a local character—namely, in the width of each individual segment, and in their thicknesses, the amounts of which are almost inappreciable.

Each glued segment binds its fellow, and the wheel is as strong as a wooden structure of this form can possibly be made, while the application of varnish prevents the glue from becoming moistened and working out of the joints by the action of the damp foundry sand. The drawing [61] illustrates the commencement of the building up, the first segments being glued to the face plate with paper joints. A pattern of a sheave pulley built up in this way is shown in plan, and half external view and half sectional view in 62, with its dividing joint along a—a. The arms, also divided, it will be noted, are made of three separate pieces, lap-jointed together with "halvings," and are therefore strong, the grain being straight in each. A

BROAD TYPES OF PATTERN CONSTRUCTION

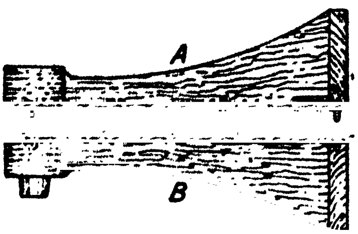
53. Example of open joints and boxing-up **54.** Boxing-up **55.** Improper method of boxing-up **56.** Halvings **57.** Lagged-up column **58.** Warping of solid timber **59.** Complete pattern column lagged up, with attachments **60.** Ring built in segments **61.** Commencement of the work **62.** Complete sheave-pulley pattern, built up in segments **63.** Pipe pattern, jointed along the centre **64.** Unjointed pipe pattern **65.** Iron pattern, unjointed built-up wheel is the perfection of pattern work, and will stand moulding from hundreds of times.

Metal Patterns. We have already mentioned the fact that metal is used for some patterns in preference to wood, with the reason for its employment. Cast iron, brass, white metals, are pressed into service. Always in such cases a pattern of wood or of plaster has to be made first, having double shrinkage, one shrinkage for the metal pattern, the other for the castings moulded from the latter. Generally, too, allowances must be made on the metal pattern for filing or tooling, to produce surfaces smooth enough and sufficiently accurate for moulding from. Lead and leather are both used frequently in patterns, the first-named for those which have to be of curved and awkward forms, the lead pattern being used from which to mould one in iron or brass. Also, the two materials are employed largely for lining up and thickening portions of patterns to effect slight alterations in them.

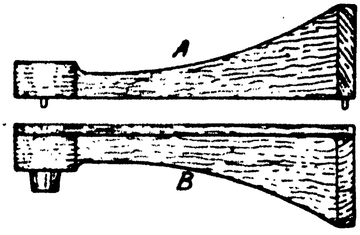
Varnish. Patterns are varnished to protect them from the moisture present in the sand, to preserve them, and to facilitate their withdrawal. A plain shellac and spirit varnish is generally used, in its natural yellow colour. Sometimes lampblack is mixed with it, and used on core prints to distinguish them from the other portions. Large cheap patterns are sometimes seared with a hot iron. Large patterns for permanent use are sometimes protected with two or three coats of oil paint.

Jointing Patterns. We will now consider the pattern from the point of view of its delivery from the sand. This, as has been illustrated in the two preceding articles of this course, involves the great question of jointing.

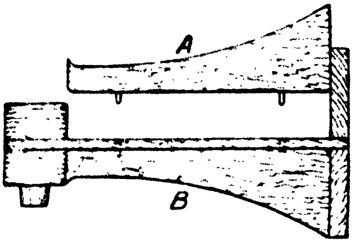
An observant youth on going into a pattern shop or a pattern stores for the first time would at once be struck by the fact that very few of the patterns were whole or entire. The bulk of them, probably nine-tenths of the total number, are pieced up, jointed in some way or another. Sometimes they are divided down the centre only, into two symmetrical halves; sometimes there are several divisions, in planes parallel with each other. Or the pattern, as a whole, is unjointed, but subsidiary portions are jointed in a loose and readily removable fashion. But in all cases means are taken to preserve the due relative positions of the several parts, so that when in their proper places with closed joints there is no risk of those relative positions being changed. The means employed to preserve these relationships are seen to be pins, or dowels, dovetails, and skewers, or wires.



66. METHOD OF JOINTING BRACKET PATTERN



67. METHOD OF JOINTING BRACKET PATTERN



68. METHOD OF JOINTING BRACKET PATTERN

Reasons for Jointing. If, from the pattern shop the student goes into the foundry, he soon learns the reasons for this jointing—that without it there would, in many cases, be no possibility of withdrawing the patterns without producing violent disturbance and fracture of the sand, quite destructive of its accurate shape and outlines. He sees that the joints in patterns, and in foundry boxes and moulds generally, correspond, but that in others they do not, except in an approximate fashion. In this way he learns the difference between the plain and obvious joints of boxes, and those of sloping joints, drawbacks, and rings of sand carried on grids. In many cases, also, though joints are not absolutely necessary for the proper withdrawal of the pattern, they are seen to be nevertheless desirable, either for the easier cleaning up of the mould, or for the insertion of cores, or to save additional jointing of moulding-boxes. Further, he observes the reason why dowels, dovetails, and skewers are employed, since without them the pattern sections would become moved relatively to one another in the mould by the process of ramming; hence he will conclude that proper jointing lies at the very foundation of the art and trade of pattern-making, and that there is only one reason for the jointing of patterns—namely, to facilitate the clean withdrawal of the pattern sections from the mould.

69. VERTICAL SECTION THROUGH MOULD OF BRACKET PATTERN

Varieties of Joints. The plainest and commonest joints are those which coincide precisely with the joint of the mould and of the moulding-box. This type of pattern is represented by the cylinder, pipe, or column, jointed longitudinally down the central plane or axis. This divides the pattern into symmetrical halves, one of which goes in the bottom, and one in the top box. Fig. 63 is a pattern of this type, jointed and dowelled in the plane *a*—*a*. Nine-tenths of patterns of this type used for jobbing and casual orders, and large quantities for standard work—those of very small diameter excepted—are jointed in this way.

The exceptions to the common practice are several, but may be included under two heads, as follows: Patterns unjointed, being so made with a view to economy, and patterns made unjointed either in order to prevent risk of lapping joints in their castings, or to maintain the maximum strength possible. Thus, the pattern is often made as in 64, solidly, but leaving the top halves of the flanges loose, for reasons given in a previous section. In 63 the pattern joint coincides absolutely with that of the mould; in 64, the two only match at the jointing of the flanges, yet the joint of the mould must be carried along the central, or longitudinal, plane of the pipe, just as in 63.

Jointless Patterns. This device of making patterns without joints is adopted generally in those made of metal. The brassfounders do much less jointing than ironfounders, employing bottom, or joint boards, by which the labour of making sand joints by hand afresh for every mould is saved. Fig. 65 shows a pattern made of iron for producing the same moulds as 63 and 64. It is cast hollow, to lighten it, and the top flange, of wood, is left loose. Such a pattern is generally turned smooth in the lathe.

There is a good deal of give and take in moulding and pattern making. The bracket pattern [66—68] illustrates the fact that patterns and moulds alike might be equally well jointed in three different ways, and this is only typical of alternatives in practice that are for ever occurring. The drawings are almost self-explanatory. In 66 the jointing of pattern and mould alike takes place in a horizontal plane that coincides with the exact centre of the bracket. In 67 the joint is made on the top face of the main web, the advantage of which is a slightly stronger pattern, because the web or plate is in one thickness. In both cases the portions A A come in the top box, and B B in the bottom. In 68, the top rib only is dowelled loosely, and here the rib is the only portion that is left in the top. The mould joint, instead of being in a strictly horizontal plane, follows the outlines

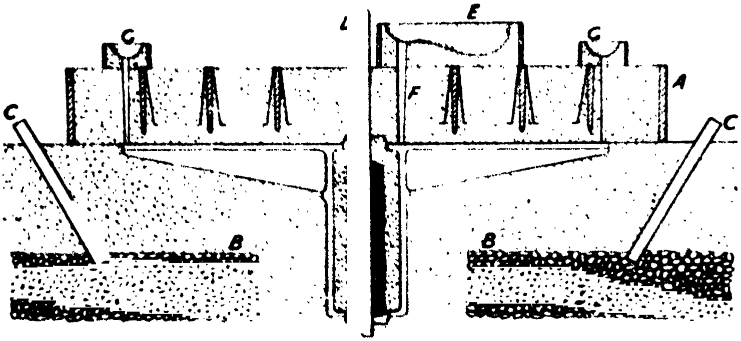
shown in 69, the rib and a bit of the boss being the only portions in the top of the mould.

Systems of Moulding. Turning now to the great divisions of the moulder's work, we revert to the remarks made on page 2110 of this course relating to the differences in sand—strong and weak, green, dry, loam—and cores. In the main these coincide with the great divisions which exist in foundry work, but not absolutely so. A more natural and all-embracing classification is that of bedding-in, turning over, sweeping, and machine moulding. Both strong and weak sands are used in bedding-in and in turning over, both green sand and loam in sweeping up, and cores are present in every class of work. Machine moulding deals with all kinds of sands, loam excepted, but it is done principally in green sand. We shall consider presently the broad methods just enumerated, prefacing the subject with a brief mention of the principal tools common to all branches alike.

Moulders' Tools. The group 70—85 illustrates the principal tools used by moulders. It will be noted that they mostly belong to the same broad divisions as those employed by plasterers and modellers—that is, they impart shapes to the sand by pressure chiefly, and that their shapes are generally the counterparts of the impressions they produce. Rammers are an exception. Some were shown on a previous page [2111].

Running through the group, 70 is a small *bench rammer*, double-ended, the upper end in the figure being the pegging end, the lower end being for flat ramming; 71 is a *cleaner*, used for smoothing vertical faces in narrow openings or the bottoms of narrow spaces (as shown in 72); 73 is another form of cleaner; 74 and 75 are front and edge views of a *boss tool*, employed for smoothing the edges and bottom faces of boss moulds, and made double-ended with different radii; 76 is a *flange bead*—that is, its curved working ends are rectangular in cross-section for smoothing the edges of flange moulds. If made with flatter curves, it is a *girder tool*. Similar tools made convex in cross-section are *bead tools* or *circular beads*. Fig. 77 is a *trowel* made in four forms—the *taper* trowel shown, the *square*, or *Scotch* trowel, the *long heart*, and the *broad heart*; and double-ended with an iron connecting shank, as the *heart* and *square*, all for smoothing flat faces of sand, and much useful work besides. Figs. 78—83 are various *sleekers*, or *smoothers*. As each is shown in the act of [illegible] a body of sand the utilities are apparent. Figs. 78 and 82 are *square-corner sleekers*, but 79 is a *round-corner sleeker*. Figs. 80 and 81 are *pipe smoothers*; 83 boasts the title of *button smoother* or *bacca-box smoother*; 84 and 85 are *vent wires*, and 84 is commonly used as a *picker* for withdrawing small patterns.



86. VERTICAL SECTION THROUGH MOULD MADE BY BEDDING-IN

Bedding-in. The sphere of bedding-in lies mostly in heavy work which is too large for the capacities of ordinary moulding boxes. The pattern is rammed in the floor sand in the position corresponding with that of its casting—that is, bottom side lowermost—and the mould is covered with a plain top-box. The method is also adopted in patterns of medium dimensions if boxes of suitable size or shape do not happen to be available. It is, moreover, to some extent decided by the general practice of a given shop, some foundries doing more in this way than others. There are several disadvantages in its adoption, one of the principal being the difficulty of ensuring even ramming, another the necessity for laying down a cinder-bed to receive the air from the vents.

Bedding-in assumes two phases—that in which the surface of the bed is level, or approximately so, and that where the form is very irregular in the vertical planes. In the first case a bed is levelled, using two winding strips set in the sand with a spirit level, and making their upper edges the guides by which to strickle off a truly horizontal bed, upon which the bottom face of the pattern is laid, to be succeeded by the ramming of the sides. Level beds are also often made with a plain striking-board attached to a central bar. If the board be truly horizontal it is evident that the bed will be horizontal also in every portion of its area.

Bedding-in Irregular Patterns. But when the lower face of a pattern is of irregular outlines, or shallow and deeper in different parts, the pattern has to be lightly beaten down into the sand and removed, and the sand gone over in detail by the moulder carefully ramming it to suitable consistency, and this may have to be repeated three or four times in succession before the pattern makes a proper bedding. The ramming of the sides is easy enough, but it is obvious that the bottom sand—that underneath the pattern—cannot be rammed while the pattern remains in place.

Fig. 86 illustrates a vertical section through a completed mould made by bedding-in, with top box A, cinder-bed B, and vent pipes C C. D is

the vent pipe from the boss core, E the pouring basin, F the runner, G G flow-off gates, or risers. Lifters will be noticed suspended from the box bars.

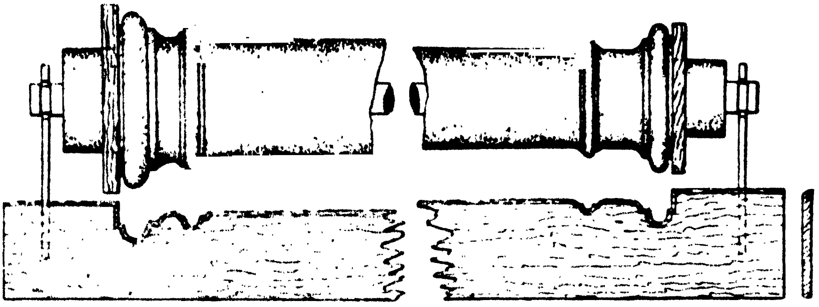
Turning Over. In this method, which includes much the larger majority of moulds made, the face of the mould that is lowermost at the time of casting is rammed first and uppermost, to be turned over subsequently. The great advantage is that the sand is rammed directly against the face of the pattern, and therefore its proper consolidation is more easily effected than by bedding-in.

To mould by turning over, the pattern is first laid on a very loosely rammed body of sand either on the floor or on what is to be the top box, and with its bottom face uppermost. Fig. 87 shows the first stage in moulding a spur wheel laid upon the top box. A joint face (*a a*) has been made on the body of sand roughly shovelled into A and tramped down, the joint face dusted with parting sand, and the box B, which is to come in the bottom, has been laid on and rammed over the pattern face and down the sides of the teeth. The two box parts being then cottared together, are turned over [88], bringing the bottom box (B) into the position which it will retain until casting. The top (A) is then lifted off, its comparatively loose sand knocked out, the joint face brushed over, strewn with parting sand, and then set over for its permanent ramming on the top face of the pattern. It is then lifted off its fellow, and the pattern is withdrawn. The mould is then cleaned and cored, and the top put on, the pouring basin made—the stage seen in 88—and the metal run into the mould.

Sweeping. This is an important economical section of foundry work. It signifies the making of certain moulds without patterns—those moulds which, being of symmetrical shapes, can be prepared by a process of formative scraping, *sweeping*, or *strickling* of sand, and of loam. It includes work both in green and in dried sands, and in plastic loam, the formation of cylindrical, annular, and curved cores in core sand and in loam. It may also be either that a mould or core is produced wholly by this process, or, as is often the case, that the main portion only is so made, and for which several separate pattern pieces have to be prepared in wood and embedded. Allied to this is the sweeping of large patterns in loam instead of making them more expensively in timber, and then, too, wood pattern parts are often attached to loam bodies. These afford very many examples of mutual give-and-take between moulder and pattern-maker, with the *object of* economical manufacture.

Methods of Sweeping. Sweeping up is done first by the revolution of a board set vertically, having an edge cut to any required profile, and chamfered, and fastened to a spindle at a certain definite distance from the centre of rotation—works in loam are commonly struck or swept thus—or, secondly, by the revolution of a horizontal core-bar, with its covering of haybands and loam against a similar board laid on trestles. Cores are struck up in this way. Or, again, by the guidance of a templet or strickle against the edge of a plate, or a rod of iron, either cores or loam patterns whose outlines are not symmetrical in the longitudinal direction are readily struck up. In each case the pattern-makers' work is almost nil, while moulder is rendered more responsible. The importance of an intimate knowledge of the entire details of sweep-work, including the choice of the best and most economical methods of striking up, the most practicable details, the conditions under which moulds and cores must be made is therefore indispensable.

Green Sand Sweeping. Figs. 89 and 90 illustrate how a mould is swept up in green sand. It is a large dished cover, the pattern for which would be expensive, but the boards would cost little, while the time occupied in sweeping not be much greater than would be spent in moulding from a pattern.



93. A LOAM PATTERN MADE BY SWEEPING UP

Two striking-boards are required. A in 89 sweeps a dummy mould upon which the top box is rammed; B then is substituted to strike the bottom directly. Or the top might be swept directly by a board cut the reverse to A, the top mould being then turned over on the bottom one. Or the convex side of the cover might be moulded downwards instead of upwards.

Cylindrical Sweeping. Cases that are always occurring are the sweeping of cylindrical cores, loam patterns, and loam moulds, with or without extraneous fittings. In each of these, loam is struck against the edges of boards which are the counterparts of the forms struck, or the profile boards are worked over the loam. In the making of wooden patterns or core boxes of large dimensions, all intricate and involved outlines, curves, and mouldings materially increase the expense of pattern work, often rendering it out of all reasonable proportion to the cost of the casting or castings required. But the expense of cutting the striking edge of a board or boards is a mere trifle, and is not affected at all by the question of diameter, that being then a question of moulder's labour and not of pattern work at all. The question of relative cost between striking-boards and complete patterns would be usually one of a few shillings versus many pounds.

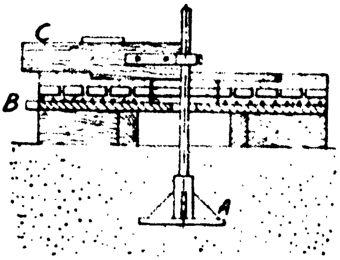
Examples of Sweeping-up. Fig. 91 illustrates the sweeping up of a core A, for a fusee drum, against a board B; C being the core-bar, pierced with vent holes. The outline of the pattern is seen marked upon the board as a guide to the moulder in setting the core in place. This device is a good one to adopt. Fig. 92 shows a core in section for an with its board. The central core-ba to be encircled with plates to retain the haybands, on and among which the loam is plastered. The end plates have prods to carry the loam there. Fig. 93 is a column pattern swept in loam against its board, the board being shown withdrawn away. Here the top and bottom flanges are made separately in wood, and slipped on the loam body. The iron bar seen projecting at the ends has journals turned on it to run in the core trestles. The body of the loam is built up on plates and hayropes as in 92.

Work which is in the main symmetrical, as in 93, often includes other attachments of more or less irregular outline to be made as parts and fitted to the struck-up pattern, core or mould. The flanges in 93 are a mere nothing in comparison with the fittings to, say, a hydraulic cylinder. Sometimes these are so numerous that it becomes a question whether in view of the time occupied in making and fitting such pieces to the circular portion of a mould —with the possible risk of their becoming displaced—it is not cheaper to make an entire pattern of wood. Such jobs do occur frequently, occupying the border-line between economical and non-economical striking up of work.

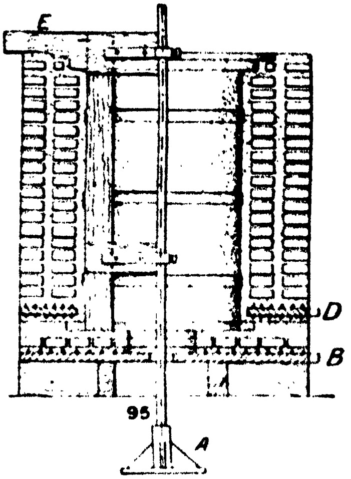
Sweeping in Loam. This involves the employment of bricks as a skeleton framework to support the loam, and the use of iron rings to carry the bricks. This is a distinct branch of moulding, involving very different methods of treatment from those of green sand work, and it is usually practised by men who do not work in green sand. The main outlines of the moulds are produced by means of a board or boards having chamfered edges, and attached to a central bar turning in a socket. In many, or in most cases, there will be portions that cannot be swept, but for which pattern pieces will be wanted, and these are embedded in the loam, being set by measurement, and so constructed as to be readily withdrawn after the loam has become partially or wholly set.

The brickwork skeleton or framework of a loam mould which forms the backing for the loam is cemented together also with loam, and the *spacing of the joints is left wide to permit* of due shrinking of the mould, and of sufficient venting spaces. In situations where the shrinkage is considerable, or where it is necessary to cut away portions of the mould, or where a portion of the mould has to be rapidly removed soon after casting, loam bricks—that is, loam moulded in the form of bricks and dried—are used.

Loam moulds generally make the best castings, because, owing to the moulds being thoroughly dry, there is much less gas generated than in green sand moulds; and the surface of the mould is hard, and therefore better able to withstand pressure of metal.



94



95

97

STAGES IN SWEEPING UP A LOAM MOULD

Cylinder Moulding in Loam. Figs. 94 to 97 illustrate the moulding of a plain cylinder in loam. The socket is seen at A, carrying the striking bar to which the boards are attached. The plates, bricks, and loam are all shown. Briefly, the sequence of operations is as follows:

The base of the mould is the plate (*B* in 94) prodded, and which, being bricked over, receives the loam, swept to outline with the board (C) that forms the bottom flange. This is then dried in the stove. Upon it another plate (D) has to be carried to sustain the outside of the mould, and this plate has to be swept over on both sides, the lower side to make a joint with the loam on B. This involves sweeping, drying, and turning over into place in order that the outer mould shall be built up on it, in which position it is shown in 95. As the loam would tumble down and fill up the flange already swept, this is temporarily filled with sand [95] during the building up of the bricks on D, and the sweeping of the mould with the board (E). This is then dried while the core, and the top, or cope, is being swept. The core is built around bricks on a plate [96] with lifting eyes, by the sweeping board (F). The cope is swept up similarly to the bottom [94], and dried and turned over into place, after the insertion of the core [97], completing the mould. The top and bottom plates being clamped or bolted together fasten the mould securely, and the annular pouring basin is made within an iron ring on the top plate [97].

CLASSES OF VEHICLES

A Comprehensive Description of Passenger and Goods Vehicles for Road and Railway, for both Private Use and Public Service

By H. J. BUTLER

THE formation of roads and their maintenance is one of the chief factors by which the progress of a country is determined. Being given these means of communication, the next step is to make the best use of them by the employment of suitable vehicles whereby we ourselves may be quickly and safely conducted from one place to another, and by means of which all classes of goods may be transported with despatch. The advent of the railway at the beginning of last century was a big step forward in the development of vehicular traffic, and made an enormous difference to trade and the welfare of the country generally. At present we have the advent of the motor-car, which will develop the use of our highways to the utmost.

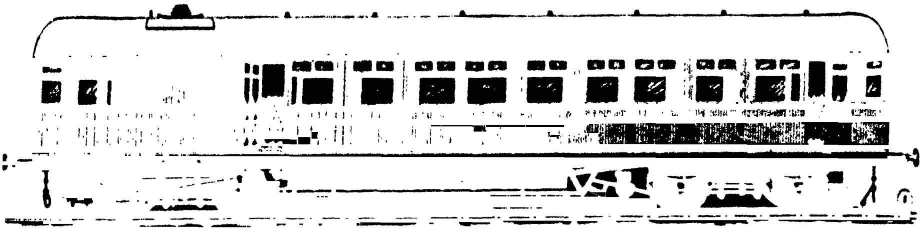
Surely, then, the study of the different classes of vehicles may call for our interest, seeing that we depend so much on their existence. In their variety, and the ingenuity displayed by their constructors, there is much that is interesting and worthy of examination.

Classes of Vehicles. Vehicles are broadly divided into two classes: (1) Passenger Vehicles; (2) Goods Vehicles. Passenger Vehicles may again be subdivided into: (*a*) Railway Rolling Stock, including Tramcars; (*b*) Motor-cars and motor-cycles; (*c*) Carriages, private and public; (*d*) Cycles. Goods vehicles also have their subdivisions. The more numerous class are separated into: (*a*) Railway and Tramway Rolling Stock; (*b*) Motor-cars; (*c*) Vans, Waggons, Carts; (*d*) Cycle Carriers, Trucks, and other small types.

Passenger Railway Vehicles. Passenger railway rolling stock serves the business man for getting from suburb to town, and from one town to another. Four and six wheeled carriages, fitted with separate transverse compartments, constitute a type that has had its day. The introduction of the four and six wheeled bogie or pivoted under-carriage at once allowed the increase in the length of the vehicle, and now we have carriages up to over 70 ft. in length. Some of the recent types are veritable travelling palaces of comfort, and are fitted up as breakfast, luncheon, dining, and picnic saloons, and adapted for the preparation as well as the serving of meals. Thus one may sleep, read, smoke, observe the country through which one passes, stroll from end to end of the train, and, where long distances are encountered, as on the continent of America, one's personal comfort is studied, even to the ministrations of the barber. Trains nowadays are well lighted in the later types, besides being heated more effectively, and, should emergency arise, means are provided to gain assistance. Even on trains running comparatively short distances every lavatorial convenience is supplied, every effort being made to combine the pleasures of travelling with the comforts of home.

Although so much thought is displayed on the interior in railway work, it must be admitted that the exterior, although plain, is neat and symmetrical.

Types of Railway Carriages. There are first, second, and third-class carriages, which may be of the compartment, corridor, or corridor-vestibule type. *Composite* is a term applied to carriages accommodating more than one class of passenger, and if with a guard or luggage compartment is termed a *brake composite.* Brake-vans are those entirely set apart for luggage and the travelling custodian of the train.

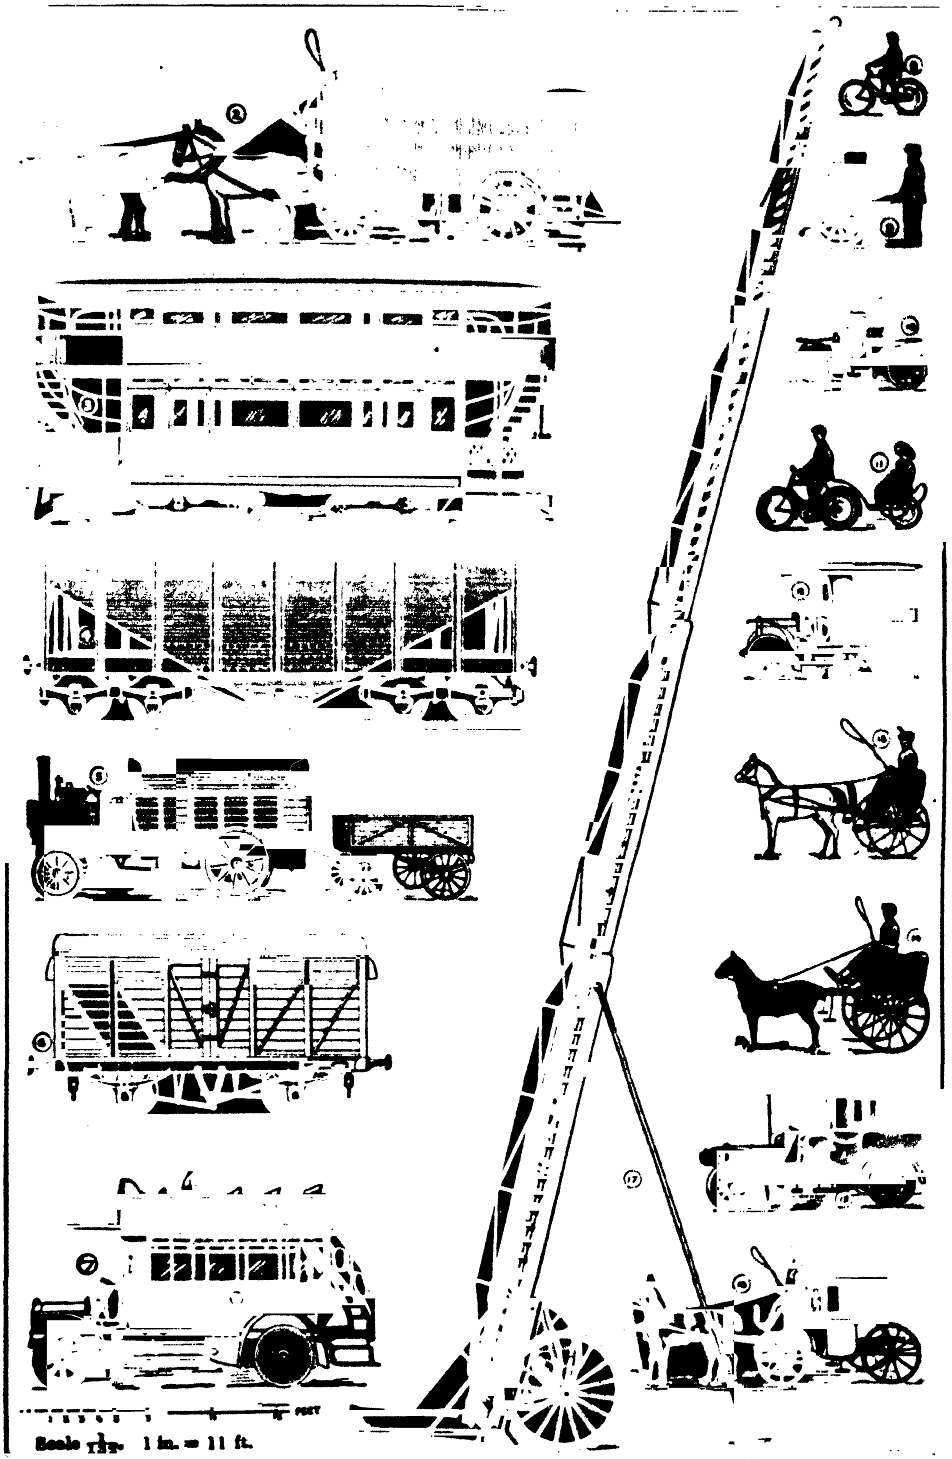


1. RAILWAY STEAM MOTOR COACH

Besides dining and sleeping cars and those already mentioned, there are family saloons and various special cars, such as are provided for Royalty. Under this heading may be included the various mail vans, for they usually travel as a part of a passenger train.

Railway builders do not favour the double-deck style, but carriages of this type may be seen around Paris and in Portugal; their further construction, however, is being discontinued. This type of vehicle is closely allied to our street double-decked tramcars, which we shall now consider.

Tramcars. Tramcars are single and double decked [3]. The horse-drawn variety is on the wane, and although cable, steam, compressed air, and other mechanical means are, and have been, used, the electric car, be it on



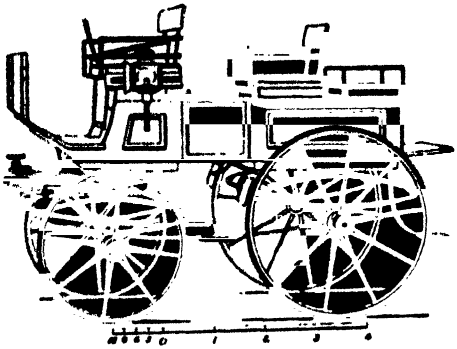
Scale $\frac{1}{132}$. 1 in. = 11 ft.

VARIOUS TYPES OF VEHICLES DRAWN TO A UNIFORM SCALE

2. Pantechnicon drawn by three horses 3. Double-decked, conduit system, electric car 4. High capacity hopper waggon, central discharge 5. Five-ton steam van with 3-ton trailer 6. Covered railway goods waggon 7. Double-decked motor omnibus 8. Juvenile cyclist 9. Baker's barrow 10. Two-seated petrol car 11. Petrol motor cycle and trailer 12. Petrol light delivery van 13. Lady's driving car 14. Butcher's cart 15. Seven-seated petrol motor car 16. Double brougham 17. 85 ft. 4-ladder fire escape, standing on its own support poles and fully extended.

the trolley or conduit system, is no doubt the type that is before us, unless the motor omnibus people succeed in proving effectually that their system is more economical, especially when ratepayers have to be considered.

Trams are suitable for conveying passengers from one to six miles, and, as may be expected, are keen rivals to the suburban railway traffic.



18. BEAUFORT PHAETON

The single deck, practically monopolised in the States, may have a closed body or be open to the floor or waist. *Composite* (a different designation to the railway term) cars consist either of a closed central general compartment and closed end smoking compartments with seats on the platform, or the centre part only may be closed and the rest open. The double-deck types have their various forms of stairways, more or less successful in keeping the streams of passengers to the roof and interior separate, and both classes may have end vestibules to form protection from the weather, and the seating may be either of the transverse or longitudinal type both inside and outside.

Motor-cars. Motor-cars that convey passengers are divided into *touring* or *pleasure* cars and those set apart for *racing*. In the general design of the body of the motor-car one sees a certain originality in the outward form, and, being a speedier vehicle than its horsed prototype, much development has taken place in schemes for protection from the weather. The speed also determines that the body shall be panelled and not of the open sticked or simple rail type, a remark of course applying to railway work.

The engineer classes the various types under the different makes of engines and means of transmission. The coachbuilder makes his divisions according to the type of body. The small *two-seater* [10] is sometimes fitted with a third fixed or collapsible seat, and occasionally a vis-à-vis seat. The two-seated vehicle in a simpler form, with more powerful mechanism, becomes a racing car. Sometimes the car is enclosed, and then resembles a brougham without a driving-seat.

Then comes a large class, the *tonneau*, a type that has a special plan shape, first being made with cramped proportions, and hind or front entrance, now more comfortably designed, and, as in many other types, fitted with a side entrance. *Limousines* [21] are bodies that are enclosed, not [illegible] the driver's seat, and in which the occupants [illegible] forward. Entrance is made from the front, side, and back.

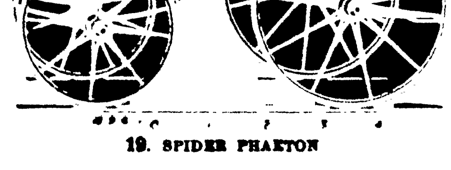
In the body of a *waggonette* one sits face to face along the length of the vehicle. When fitted with a side-folding leather head it is termed usually a *Lonsdale waggonette*. A waggonette fitted with a solid top becomes an omnibus. Often the top is removable, a remark applying to limousines.

Motor Omnibuses. *Omnibuses*, as their name suggests, are used for public service purposes, and London, in conjunction with other towns, is daily increasing the number on the streets. There is the small private type, seating from four in the body, to the double-deck public service omnibus, holding in all from 32 to 42 passengers [7].

A favourite vehicle that has been copied from the horse-drawn type is the *landaulette* [22]. This has a folding head, making the carriage suitable either for fine or bad, hot or cold weather. It can be used for shopping, paying calls, or the opera. The single type holds normally two, and the double, with its square, or Dee front, holds four in the body. The front may be either fixed or made wholly or partly to fold. The *Brougham* is similar to the landaulette, except that the top is fixed and not made to fold. Then, continuing through the list, there may be noted the various *phaeton types*, besides private and public *hansoms*; but these will be mentioned at greater length under Horse Vehicles.

The remaining patterns include *saloon*, or *pullman cars*, noteworthy for the luxury and comfort of their fitments, and the various large cars seating six, seven, and eight persons.

All types, except those already fitted with weather protection—*viz*., broughams, landaulettes, limousines, and single-deck 'buses, have designed for them when required various folding leather heads, cape cart and double extension heads, canopies, and glass screens placed in the front, the centre, or the back of the car.



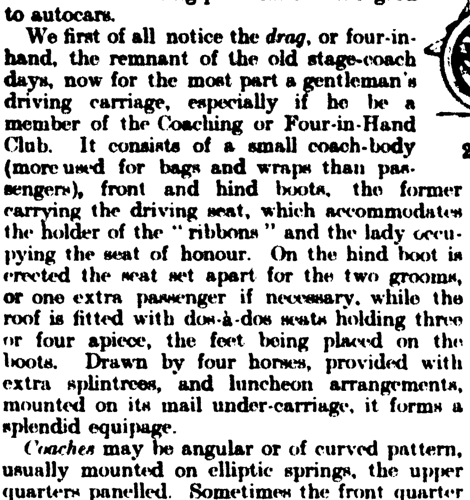
19. SPIDER PHAETON

Motor-cycles. *Motor-cycles* [11] are more popular in the two-wheeled form, and represent the cheapest form of the automobile. Tricycles are not so much used as formerly, and when more than two wheels are adopted it is usually in the form of the tricar or "quad"—a class of vehicle which in some instances resembles closely the lighter forms of motor-cars.

Horse Carriages. This brings us to the trade that is much threatened, especially as regards new work, owing to the coming of the automobile. Still, the principles of construction used in this work are the basis on which railway carriages and motor bodies have taken their copy, and it will be remembered that the earlier types were so like their horse-drawn examples that the new form of locomotion brought upon itself much contempt. In the same way that railway-carriage builders have designed for themselves special vehicles suited to their needs, so a similar process of evolution is being performed with regard to autocars.

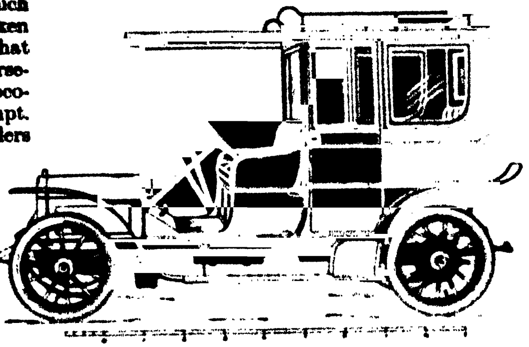
We first of all notice the *drag*, or four-in-hand, the remnant of the old stage-coach days, now for the most part a gentleman's driving carriage, especially if he be a member of the Coaching or Four-in-Hand Club. It consists of a small coach-body (more used for bags and wraps than passengers), front and hind boots, the former carrying the driving seat, which accommodates the holder of the "ribbons" and the lady occupying the seat of honour. On the hind boot is erected the seat set apart for the two grooms, or one extra passenger if necessary, while the roof is fitted with dos-à-dos seats holding three or four apiece, the feet being placed on the boots. Drawn by four horses, provided with extra splintrees, and luncheon arrangements, mounted on its mail under-carriage, it forms a splendid equipage.

Coaches may be angular or of curved pattern, usually mounted on elliptic springs, the upper quarters panelled. Sometimes the front quarter is glazed, but very seldom the hind quarter. Coaches carry four inside and two on the driving seat. They are not much used now, except when attending the obsequies of a friend, and they are drawn by one horse or by two horses. *State coaches*, as their name implies, are used on special occasions, and are of generous proportions and elaborate design being drawn by two or more horses, and often mounted on C and under springs.



20. PAIR-HORSE STATION OMNIBUS

Landaus and [illegible]ms. A *landau*, whether of the angular, curved, or canoe pattern, is a vehicle seating four inside, but is roomier than a double landaulette, as described under Motor Bodies, and the front seat has a folding head also, so we have a double-folding head, meeting over the doorway. This collapsible head is perhaps one of the most useful inventions applied to road vehicles. Landaus are drawn by one horse or by two horses. King Edward VII. had a new *State landau* built for him recently, and it is the only one in the British Royal household. It has been drawn by the eight cream horses familiar to sightseers. *Landaulettes* are either of the curved or angular type, and find little favour, strange to say, as horse-drawn vehicles.



21 SIDE-ENTRY LIMOUSINE PETROL MOTOR-CAR

Broughams drawn by one or two horses are curved [16] or angular [23] in outline, or a combination of the two, and are single and double, as landaulettes. A circular fronted brougham (also a landaulette) seats three in the body. All types can accommodate two on the driving seat.

A *four-wheeler* is a square-fronted brougham. A *dress chariot* is a full-quartered, two-seated body, provided, as most semi-dress, dress, semi-State, and State vehicles are, with a hammer-cloth and cradle seat, Salisbury boot, hind standards, box, bound platform, and block, all suitably carved. Sometimes a folding head is provided. Chariots were much in vogue 100 years ago, and earlier, but now they are seldom seen.

Barouches and Sociables. *Barouches*, originally constructed with deep panels, now with shallow, are similar in shape as regards the body to a canoe landau, but only the hind seat is protected with a folding head, the front seat being protected with a flap. On C and under springs a barouche is a noble carriage when mounted with front scrolls, splasher, folding step, and high driving-seat. Barouches are also made with solid ordinary boots and mounted on elliptic springs, short wings being used.

Sociables are curved or angular in outline, and may be full or open panelled. The seats are protected as in barouches; long wings, extending to the steps, or short elbow wings, are used, and the term "sociable" is designated by the best authorities to a vehicle with a door. A *double* *victoria* is a similar carriage, but without a door, usually with long wings. A *barouche sociable* has the body of a sociable with the refinements of a barouche.

Omnibuses. *Private omnibuses* range from the single-horse vehicle carrying two on the driving seat and four in the body, to the heavy pair-horse type [20] holding eight inside, three on the roof, three on the box, and perhaps a hind groom's seat. It is used for station work. Railway companies, hotels, and other large establishments maintain their own omnibuses.

The familiar *garden-seat omnibus*, much condemned by those who themselves cannot improve it, needs no description, except to say that as regards distribution of weight on the wheels it stands unrivalled. Born in France, introduced into London by Shillibeer as a single decker, it is one of the chief items of traffic in the main thoroughfares of the metropolis.

Waggonettes carry two passengers in front and four or more in the body. Besides the *Lonsdale waggonette*, as mentioned under Motor-Cars, the *Fife waggonette*, with a large folding head, similar in operation to the front seat of a landau, is occasionally adopted.

A *waggonette brake* has a high driving-boot, is fitted for at least a pair of horses, and is often used for exercising. The largest types are well known, catering as they do for beanfeast and sight-seeing parties.

The gentleman's *char-à-banc* is made in many designs. It has normally four seats, facing according to taste, either high or low, open or panelled. It always has a high driving-seat, and is fitted for at least a pair of horses. The public service type has a use similar to that of the brake mentioned above. *Beaufort phaetons* [18] are a type of char-à-banc.

22. ELECTRIC SINGLE LANDAULETTE WITH UNDERSLUNG BATTERY

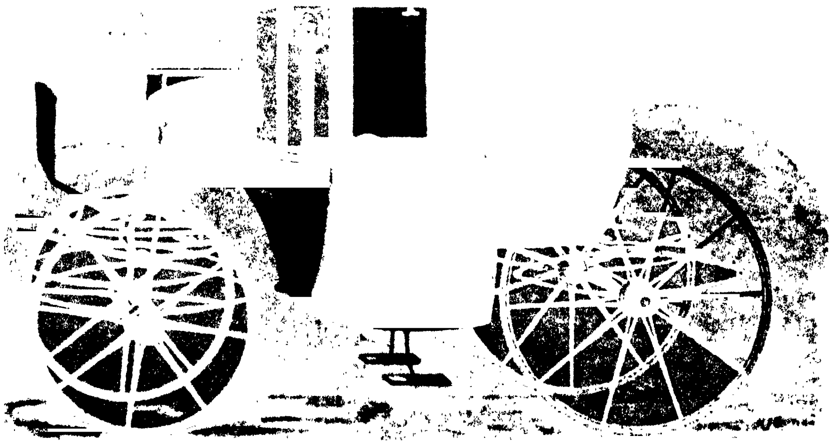
Phaetons. *Phaetons* embrace a large class of vehicles. *Victoria phaetons*, better known simply as *victorias*, are curved or angular in outline, open or full panelled. They carry two in the body, which is protected by a folding head, and is much lower than the driving seat. A *Stanhope phaeton* has a front curved pillar and rails to the front seat, hind seat with irons, oblong box body, usually provided with an arch, and folding head to front seat. If no folding head, it has a special designation—"T" cart. *Mail phaetons* are mounted on a mail under-carriage, have no arch, a heavier body with well, and are provided with a folding head similar to the Stanhope. The hind seat has a double rail. A *demi-mail phaeton* has the characteristics of both the mail and Stanhope. A *Vienna phaeton* is an angular Victoria phaeton. *Park phaetons*, or lady's driving phaetons, usually have a folding head to the hind driving-seat, with hind rumble for groom; generally a splasher in front, sometimes a vis-à-vis front seat. *Spider*, or *skeleton phaetons* [19] have a folding head to the high front seat, and are mounted on iron or wood-cased cranes, the groom's seat being at their hind extremity. *Road phaetons* and *dog-cart phaetons* have dos-à-dos seats, are adapted for carrying dogs or luggage, and are mounted on a box body, which may be slatted, or solid-sided, or provided with panels or sham louvres.

Two-wheeled Carriages. Having dealt with four-wheeled vehicles, we shall now consider briefly the two-wheeled varieties.

The *hansom cab*, most numerous of London's public vehicles, is a refinement of the type introduced in 1834. The position of the driver and the sliding front glasses are well known. Private hansoms are not uncommon, being patronised by Royalty. The hansom cab front is adopted in several types of two-wheeled carts, the advantage being its ease of access.

Gigs are vehicles seating only two, and in their different forms have been in vogue for a great many years. The *Stanhope* gig has a front like the Stanhope phaeton or waggonette, bent, strongly-plated ash shafts, and is mounted on two side and two cross-springs. The *Dennet* is a gig mounted on two side and one cross spring only, while the *Tilbury*, now little used, has two side, two front elbow, two hind elbow, and a cross-spring, and the part of the body under the seat line is much cut away. Polo, or *Liverpool gigs*, or, better, *carts*, are frame-sided, two wheelers, and carry two persons.

Carts and Cars [13]. Carts and cars have many fancy names, and their variety is very great. When seating two and four, the seats generally slide, the front over the back, the hind part of the body being let down to form the footboard. The finish may be open-sided or rustic, solid, and often the top is bent, forming the mudguard as well as giving a pleasing finish. The mounting varies, sometimes elliptic, sometimes side-springs, often in conjunction with a cross-spring. Now and then imitation C springs are used.



23. ANGULAR DOUBLE BROUGHAM

As an example of bewildering nomenclature of two-wheelers, the following is a selection: Archer, Battlesdean, Canterbury, Cleveland, Concave, Covert, Dagonet, Dalmatian, Empress, Harrington, Kensington, McGorris, Manchester, Morvi, Morgan, Norfolk, Oxford, Poly, Prince, Princess, Princess May, Raleigh, Ralli, Ranmore, Royal, Salisbury, Shooting, Sporting, Stanley, Tynegate, Whitechapel and Wilberforce.

Cabriolets, with graceful, flowing lines, and generally a folding head, carry two persons. The term formerly denoted a special type of hanging. *Tandem carts* are high driving two-wheelers, often with sliding body, and are used as the name indicates. There are many other types, both two and four wheeled, but space will not permit of greater detail. Among foreign types the American platform waggons, curricles, buggies, surreys, concords, and runabouts are quite distinct in general appearance from anything else previously mentioned.

Cycles, in the form of bicycles [8], tricycles, tandems, and other multi-seated types are so familiar as not to require any more than mention

Vehicles for Goods. We now come to the strictly utilitarian type—*goods vehicles*. As in passenger railway work, the bogie has revolutionised the design of goods waggons, and together with the adoption of pressed steel and other frames, an entirely new pattern of useful vehicle is being brought into use [4]. Not only cheaper in haulage and in outlay, but the tare in comparison to the load is in itself a great reason for the adoption of this new stock. Slowly English railways are taking to themselves what has already been long in practice, especially in America. They are called *freight cars*; the large box-cars are specially constructed for carrying furniture, road vehicles fitted up as refrigerators, and for the conveyance of live stock, coke, barrels, etc. The hopper cars carry coal and ore [4], and the low-sided gondola cars have similar uses. Machinery, tramcars, boilers, girders and other large articles have long trucks built for their transport. Our own 10, 15, and 20 ton four-wheeled waggons [6] are a well-known sight on the sidings, and brake, fish and gunpowder vans are also familiar. Tramway companies have their own water, salt, sanding and ticket waggons. *Vans*, *waggons*, and *carts* mechanically propelled or animal drawn have all specific vehicles designed for the special trade or commodity they are destined to carry.

Trade Cycles and Trucks. The *cycle* as a trade vehicle is seen in the cycle carrier. Butchers, stationers, fruiterers, tailors, and other tradesmen find it quick and economical for the delivery of goods.

One might easily fill a moderate volume with the description and interesting points of *trucks*. We see them as useful adjuncts at railway stations; in the factory they are invaluable; the Post Office places huge orders for them; the baker's barrow, the milkman's perambulator, all have their constructional differences.

TAILORING

continued from p. [illegible]

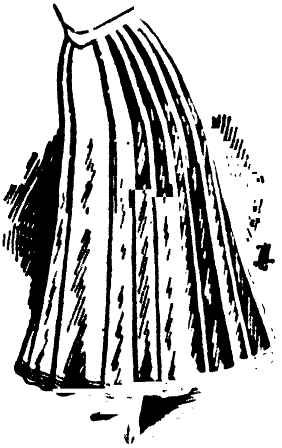
TAILORING FOR GIRLS

Drafting and Making Girl's Box-pleated Skirt. Fastenings, Waistband, and Lining. Drafting & Making Sacque Coat. Measurements & Materials Required

By Mrs. W. H. SMITH and AZÉLINE LEWIS

As the methods employed for making ladies' and girls' clothing are practically the same, we have considered two garments enough for description in this section. If the instructions given in the last portion have been carefully followed, as well as those for boys in the preceding one, the learner should be able to handle successfully any type of coat or skirt.

We will first consider the skirt, for which we have selected a box-pleated model, as this enjoys much favour at the present, and is a graceful and becoming style for walking skirts generally [85]. It requires, however, to be well cut and made, as its smartness depends entirely on the set of the pleats, their accuracy—a most essential point—the hang of the lower edge, good pressing, stitching, and finishing, and all those details which go to the making of a good tailor-made skirt. We cannot, therefore, too strongly insist upon the learner paying very careful attention to these matters, and thus profiting to the utmost from the lessons given in this course.



85. BOX-PLEATED SKIRT

Box-pleated Skirt. Diagram 86 represents the foundation which we have to work upon to model a pleated skirt.

Measurements. Waist 24 in.; hips (measure taken 5½ in. below waist easily), 36 in.; length, 32 in.; working scale, half-waist, 12 in.; half hips, 18 in. A piece of paper 37 × 43 in. is required.

The short edge of paper must be towards the worker.

The Drafting. Draw a line 1 in. down from top, letter the corner A. A to B, half waist less 1 in. (11 in.). C midway between A and B. A to D, one-fourth of waist plus ¼ in. (3¼ in.). C to E, ¼ in. less than A to D. Curve carefully from D through E to B.

D to F, 5½ in.; D to G, length of skirt (32 in.); F to H, half hip (18 in.) [see broken line]. Draw line from B through H; make I the length of skirt (32 in.); D to J, one-fourth of waist less ½ in. G to K, one-fourth of hip (4½ in.). Now measure down from waist, at equal distances, the length of skirt, to obtain the round for lower edges.

This system applies to all size waists for pleated skirts, and it is an easy matter to make them any length desired.

The directions given are for a panel front. If, however, one prefers the pleats the same distance apart all round, the spaces between the pleats at the bottom must be increased to 4 in., and those at the top to 1 in. Divide the bottom from K into 11 parts, 3½ in. apart, for the width of pleats and spaces between, leaving 1½ in. from last pleat for centre-back space [86]. This will give six pleats on the half skirt, but any arrangement is possible as to number and width.

The waist must be divided from J to B in the same manner, placing 1 in. for width of pleats, ¾ in. for spaces, and ¾ in. beyond B, or the actual waist measure (this is to be closed in under the pleats when making).

Draw lines for the pleats as in diagram. The lines on either side of 1 and 2, etc., represent the pleat folded and pressed.

It is advisable first to model the skirt pattern in soft paper, as it will be found easier to work and save a waste of material. For this purpose a very large sheet will be required.

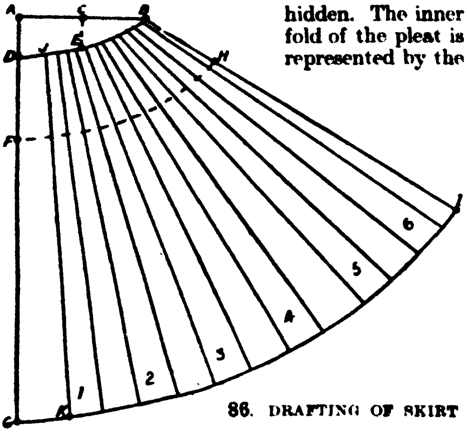
Place the paper on the foundation, edge to edge, with the greater length to the left—*i.e.*, above the waist; pin in position. Mark the waist line and the curve at the bottom (both of these will have to be watched throughout the modelling, and marked after each pleat is completed, to ensure their being correct) [87].

Make J 2½ in. from edge, and K 4½ in. from edge. Draw a line from J to K, K to L, 2½ in. (under part of pleat); J to 2, 1 in. Draw line from 1 to 2 and fold ever to meet J and K. The lines must be drawn in every instance.

1 to 3, 3½ in. (width of pleat); 2 to 4, 1 in.; 4 to 5, the same; 3 to 6, 2½ in.; fold 3 and 4 over to meet 5 and 6. 6 to 7, 3½ in. (space); 5 to 8, ¾ in. Repeat these directions until there are 6 pleats and 5½ spaces.

Perfect accuracy is absolutely necessary to make this skirt a success, both in measuring and in the depth of pleats. Remember to have the waist line and bottom curved to the foundation after the pleats are made.

Cut the pattern up at the double broken lines [87], taking care to put the notches on each gore, as these are placed together when making. A 46 in. material cuts to the best advantage for this length skirt, 3 yds. being sufficient; but for a longer and wider skirt a 54 to 56 in. material will be required. If narrower goods be used the skirt will require more gores, and the pattern can be arranged with as many as may be wished, provided that each be cut through the fold of the pleat so that the seam comes here and will thus be hidden. The inner fold of the pleat is represented by the broken line, and this is where the gores must be cut through. If cut with more gores than those shown in the diagram, care must be taken to number each gore very carefully, and to notch them well, so that the wrong edges shall not be put together, so spoiling the hang and fit of the skirt. It should also be remembered when placing and cutting out that the edges towards the front must be put to the selvedges.



86. DRAFTING OF SKIRT

To place the pattern on the material to the best advantage, providing there is no up or down, proceed as follows: Place the cloth on the table with the fold towards the worker. Place the back gore on the left hand, with the bottom 2½ in. from cut edge, and the three notches from ½ to ¾ in. (according to the material) from the selvedge; the same amount of turnings must be left on each side of every gore.

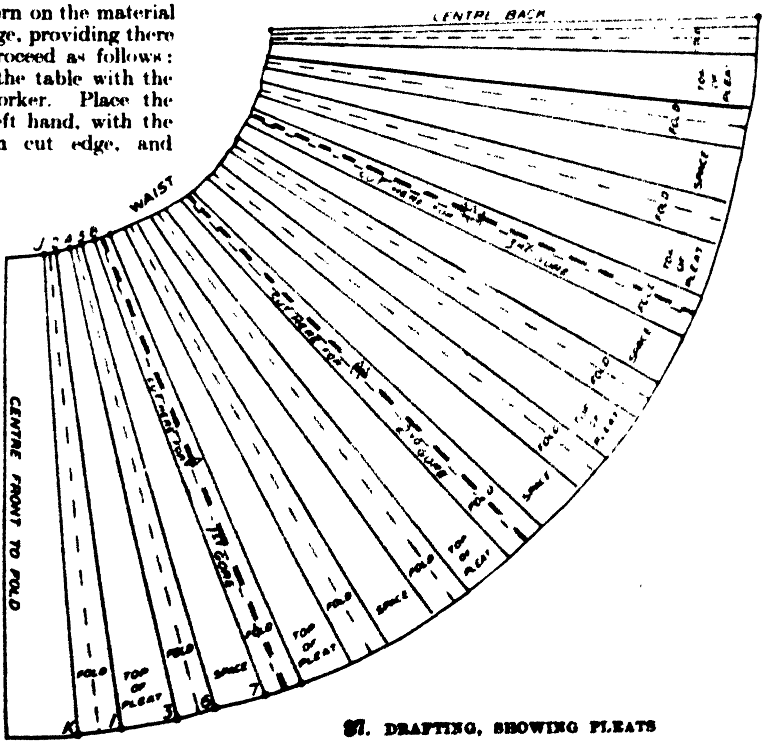
Then place the second side gore with the two notches ¾ in. from the fold, and waist to the left. Put the front to the fold, with the bottom 2½ in. from the cut edge on right hand. Now, the bottom of the first gore must be placed 5 in. from the bottom of the second one, to allow 2½ in. for turnings on each; the side with one notch must go ¾ in. from the selvedge.

The chalk-marking and measuring for this skirt must be done with the greatest care and accuracy or it will be a failure. No lining is required for a pleated skirt, but a foundation with two or three little frills can be made to wear with it if desired.

Before cutting the material, chalk all round the patterns, also every line on the waist and bottom; then remove the patterns, and with a long ruler or lath (a flat blind-stick answers the purpose very well), draw all the lines as on the patterns. Leave sufficient turnings all round when cutting the various parts.

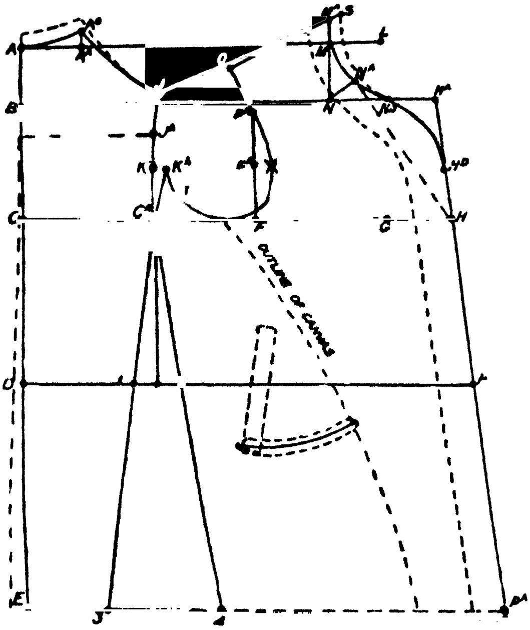
The Making. Then take a needle and cotton and put several stitches along each line and all round. Turn the parts over and chalk-mark; draw lines over the cotton to ensure their being the same on both sides; carefully mark the notches on each gore. Cut and remove the bastings—this should be done in every case to avoid damaging the material. Pin the gores together, keeping the top and bottom even and the notches together; baste carefully and stitch. Remove the bastings, and well press the seams. The raw edges must be loosely overcast. Turn up the bottom to thread-marks, baste, and machine. Remove the basting and press well.

The foot part can be, and in woollen goods more frequently is, faced with lining cut to the same shape as the foot part of skirt, from 4 to 6 in. in depth. This gives a little more substance to the lower edge and allows the



87. DRAFTING, SHOWING PLEATS

stitching to be done much higher up, which is sometimes considered an improvement. In this case, only 1 in. turnings should be left at the bottom, instead of 2½, and 1½ yd. of lining will be required.



28. DRAFTING OF SACQUE JACKET

Fold all the pleats and baste in position. Great care is needed in doing this to keep the pleats perfectly flat and even; they must be well basted on each side. Now stitch each pleat on either side, according to taste—three-quarters of the length is a good depth, graduated to about 7 in. at centre-back. If they are not stitched, they will have to be taped on the wrong side two or three times to keep them in position.

It is advisable to fasten this skirt at the back. A wrap should be put on the left side of opening 1½ in. wide and 9 to 9½ in. long, and a facing on the right side. Both sides should have a linen stay to prevent the edges from stretching, and to act as a foundation for the fasteners, which may be small spring hooks and bars. The wrap should be faced with a piece of silk or lining the same colour as material. The right side should be turned in over the linen stay, and faced with a strip of silk not more than ¾ in. wide, or it will interfere with the set of the pleat. Make the bottom of placket opening neat and secure. Stay the waist with a piece of selvedge-wise linen to avoid stretching while pressing the pleats, or the waist will be too large. To press the pleats successfully, a board is required.

Turn the skirt inside out and press each pleat with a cloth slightly damp (not wet) and a hot iron. The iron must be lifted, not moved along, and the pressing done thoroughly. After the pleats are pressed, remove the basting, and, should there be any shine left on the right side as a result, it must be pressed again with a slightly damp cloth and a warm iron over the shiny parts.

Waist Part. The waistband, of double web, must be cut 26 in. long—*i.e.*, 24 in. for waist, 1½ in. for wrap, and ½ in. for turnings. Turn in the ends ½ in. Mark off 1½ in. for the wrap; 12 in. from wrap make a mark for the centre. Place the centre of band to the centre of waist, and baste on, easing the pleats into the band. Try the skirt on, and when satisfactory stitch the band and sew on the fasteners or hooks and bar loops—in any case the band must have hooks and bars. The first one must be put 12 in. from the centre of waist and the second near the end; one hook should be placed ½ inch from the end and the other to fasten in the second bar. Sew on two hangers and the skirt is completed.

[For the finishing of the placket opening see also Dressmaking.]

The Lining. Unlined skirts are now usually provided with a lining in the front breadth, as this prevents any bulging or stretching at the knees, or clinging to the underskirt, which not infrequently happens with a soft material. In this case the lining may be carried down the full length of front, but in the skirt under consideration it would be best to have it only across the panel portion and just below the knees. It must be felled neatly to the pleat of skirt on either side and hemmed at the lower edge. The lining selected should be of a slippery nature—either of silk or glissade—although some of the new mercerised makes of lining answer the purpose almost as well.

Sacque Jacket. Our second model is a sacque jacket for girls from 14 to 16 years of age.

MEASUREMENTS. Neck, 14½ in. Chest, 31 in. Length of back, 15 in. Full length, 25 in. Sleeve from centre-back to elbow, 18½ in. Elbow to wrist, 10 in. Working scale, half-chest (15½ in.); ¼ in. turnings are allowed on all seams.

This pattern will require 1½ yd. of cloth 54 in. wide; ¾ yd. canvas; ¾ yd. sleeve lining, and 1½ yd. double-width lining.

The Drafting. Square lines at right angles 2 in. down from top of paper and 2 in. in from edge, letter the corner A [28]. A to B, one-sixth of back; B to C, two-thirds of back. A to D, length of back (15 in.). E to E, full length (25 in.). Square lines from B, C, D, and E at right angles.

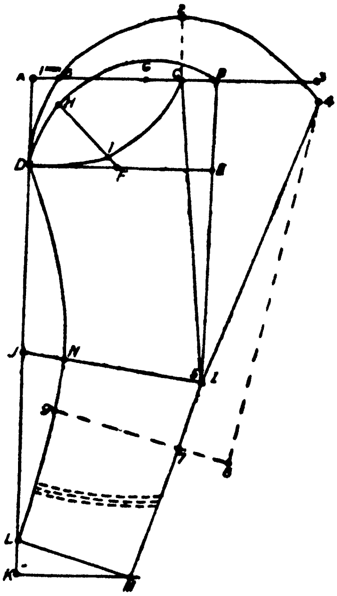
A to A^2, one sixth of neck; A^2 to A^3, ¾ in.; C to C^2, one-third of chest plus ¼ in. (for seams); C to F, two-thirds (10½ in.); C to G, half chest plus ¼ in. (15¾ in.); G to H, three inches; 3 to I, one-twelfth plus ¼ in. (1¾ in.).

Square up from C^2 to half an inch above B line; make J. J to J^2, 2 in.; C^2 to K, 2 in.; K to K^2, ½ in.; F to F^2, one-fourth of chest plus ½ in. (about 4½ in.). F^2, midway between; F^2 to X, ½ in. Square up from G to neck line; make L. L to M one-sixth of neck (2½ in.); M to M^2, 1 in. Square down from M^2 to B line; make N.

N to N^a, one-twelfth of neck plus ¼ in. (about 1¼ in.). Square up from G to B line; make N^b. N^b to H^a ½ in. less than G to H. M^a to O, the same as A^b to J; drop O a quarter of an inch. Draw the neck curves, shoulders, and armholes as in previous drafts. D to P, 1 in. more than C to H. Draw line from H^a through H to P^a for the length of coat. H to H^b, 2½ in.; M^a to S, ½ in.; curve from N^b through N^a to S; connect S to M^a. H^b to S is the neck proper. A to A^b must be raised ½ in. to correspond with front neck, and connected to J [see broken line].

Square down from C^a to waist line, and make a dot. 1 and 2 are each 1 in. to the right and left of this dot. Draw line from C^a through 1, make 3 the length of coat, and from C^a through 2 make 4. Curve from C^a to K^a.

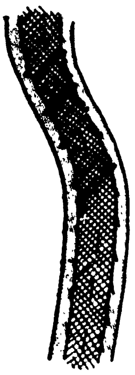
Should the back be required fuller, add 1 to 1½ in., or more, out from E, and draw line to B [see broken line, which must be placed to fold]; drop the front ½ in. and curve from P^a to 3. Any sized jacket can be made from this system.



90. THE SLEEVE

Two pockets are shown on diagram [88], a welted and a jetted—whichever may be preferred—with the making of which we have already dealt.

The broken lines at the back of neck and front represent a trimming of strapping with several rows of stitching, which makes a smart trimming, particularly if it is striped [88]. Another method is a strapping down the centre of back, and from centre of shoulders, back and front. Strapping is very fashionable, and looks well if made half an inch wide and put on to form a design. This model results in a very stylish coat providing it is carefully made. It could have revers if preferred; in this case the front would turn back as from H to N^a [see broken line, 88].



89. THE STRAPPING

Full directions have been given for making coat, revers, etc., in Tailoring for Women. The canvas should be cut (as in diagram 87) one inch beyond F, and taking in the end of the pocket. It should have a facing 2½ in. wide, shaped to the front. For full directions for inserting the canvas, linen stays, facings, and linings, in fact for general making and finishing, refer back to the Making of Boy's Coat. The strappings should be lined with very fine canvas, made and pressed well before putting on [89].

The Sleeve. The sleeve is drafted in the same manner as for Lady's Princess Robe, with a few exceptions [90]. F to 1, ½ in.; C to 2, 3 in.; B to 3, 4½ in.; 3 to 4, ¾ in.; 4 to 5 must be the same length as 5 to C. This line takes the place of B to 5. A to 6, 1 in. Curve from D through 6 and 2 to 4; this takes the place of D to B and is the top of the sleeve proper. N to 5, one-third of scale plus 1 in.

Should a full three-quarter sleeve be desired, make 7 3½ in. below 5. 7 to 8, 2½ in. Connect 8 to 4; N to 9, 2 in.; draw line from 8 to 9. This portion should be pleated or gathered into a deep band or gauntlet.

SUBORDINATE CLERKSHIPS

The Position and Prospects of Second Division Clerks. Examinations. Assistant Clerkships

By ERNEST A. CARR

FIRST Class Clerks, as we have seen, form the foremost grade of the general civil staff—that is, they are employed, not in a particular department only, but throughout the service. In the present article and that which follows we shall review in turn each of the remaining appointments on the general staff

These posts may be arranged in order of value, thus:

Second Division Clerk.
Assistant Clerk or Abstractor.
Officekeeper and Messenger.
Boy Clerk.
Boy Messenger.

Second Division Clerkships. Like the "non-commissioned man" of Kipling's ballad, the Second Division Clerk may fairly claim to be "the backbone of the service." He is, indeed, an element of considerable importance in the general economy of Government business, and in certain respects his rating may not inaptly be compared with that of an army sergeant or sergeant-major. While not enjoying anything like the position or prospects of the Class I. clerk—who is the commissioned officer of the civilian army—he holds distinctly intermediate rank in the public service, is entrusted with somewhat responsible duties, and commands the respectful consideration of his subordinates. Moreover, he has moderate chances of attaining commissioned rank. In two important respects, however, the analogy fails. As a rule, the Second Division clerk is not promoted to that grade, but is appointed to it directly; and his normal duty is not the instruction or supervision of others, but an executive task of his own.

Second Division clerks are employed in 62 Government offices, and numbered 3,440 in all when last scheduled. Of this total, 391 were then engaged in Dublin, only 111 at Edinburgh, and practically all the remainder in London—that colossal department the General Post Office absorbing no less than 1,136, or about one-third of the whole force.

Duties, Pay, and Prospects. Except for copying and merely mechanical duties, a large proportion of the clerical work of the service is entrusted to these officers. Nominally, their function is restricted to "routine work"; and in the Post Office and certain other branches the official phrase is a fairly exact description. In many departments, however, they are occupied with involved or confidential tasks to which that definition does not apply at all, and for which their pay is certainly inadequate. In this way, on the other hand, claims to promotion are often established. "The special character of the duties performed" is the reason most frequently assigned for such advancements.

The Second Division clerk may be required to perform temporary duty before receiving a permanent appointment, and during the first year of his service on the establishment is upon probation. His hours of duty are seven daily, with a half holiday weekly or on alternate Saturdays, according to the custom in individual offices. In addition to the usual public holidays, the annual leave for clerks of less than five years' service is fourteen working days, and for their seniors twenty-one working days—that is, three weeks and a half.

Second Division clerks are remunerated as follows. Starting at £70 a year, they advance by £5 annually to £100, and thence by £7 10s. to £190, afterwards progressing by £10 increments to £250, and on entering the higher grade, to £350. Promotion to the higher grade is not automatic, but depends on merit, the regulations providing that although an appointment to this grade shall be made whenever a clerk attains his £250 limit, the promotion will not necessarily be of that particular officer. This provision is by no means a dead letter. It happens not infrequently that an indifferent clerk is left waiting at the £250 barrier, while a more efficient junior, who had not attained that salary, is advanced to the higher grade in his stead.

Another incentive to good work is the recent regulation that a clerk of not less than six years' standing may receive, as a reward for exceptional merit, a special increase of salary not to exceed four annual increments.

Apart from such individual advancements the progress of the Second Division clerk is certainly slow. A simple calculation shows that in the ordinary way his maximum salary is reached only after 34 years. Yet, the certainty of his position, its steadily advancing stipend, and the fair prospects it affords of promotion to the better paid posts, combine to make Second Division clerkships among the most eagerly contested appointments in the national service.

Promotion. The regulations provide that after eight years' service these officers are eligible for advancement to the first class. Hitherto, however, such promotions have been sparingly made, averaging only three or four cases yearly. On the other hand, a number of less valuable staff posts, with salaries ranging from £400 to £750 a year, are reserved for meritorious members of the Second Division. About 30 promotions of this character take place every year. The proportion of these higher positions differs greatly in the various branches. The Colonial Office, Home Office, and other great administrative departments afford many such openings, while in the Post Office they are conspicuous by their absence. Successful competitors are usually allowed, in order of merit, a certain—or rather, an uncertain—range of choice among the numerous offices. But their selections are necessarily often disregarded, the appointments being determined mainly by the occurrence of vacancies. Candidates should, therefore, recognise clearly at the outset the possibility that they may find themselves, through no fault of their own, practically debarred from advancing beyond the £350 yearly which is the maximum of the Second Division.

To an ambitious officer thus unfortunately placed there is one avenue of advancement always open, at least during the earlier years of his service. He may employ his leisure in studying for one of the examinations by which better-paid appointments are recruited. For this task he will be peculiarly fitted, not only by his previous training, but also by the valuable extension of age allowed (as explained on page 2161) to candidates already in the National service.

The Examination. Open competitions for Second Division clerkships are held once or twice yearly, the number of appointments offered at each varying between 50 and 300, according to the needs of the departments. Candidates must be between 17 and 20 years of age on the first day of the examination, but boy clerks and others who have served for two years or more in a Government office may enter until 22 years old.

The educational scope of these contests corresponds generally with that of an ordinary second grade school. There are, in addition, a few special Civil Service subjects such as few schoolmasters teach. They comprise copying manuscript, précis, and digesting returns. For the first of these exercises the candidate is given a lithographed copy of a badly-written document, so altered and interlined in parts as to be almost undecipherable. Of this he is required to make, in the half-hour at his disposal, a neat and clearly legible transcript, with as few erasures as possible. A little practice with the specimen manuscripts included in former examination papers robs this test of its terrors.

Before starting to write, it is useful to glance down the lithograph, so as to grasp its general purport. Difficult passages are best deciphered by a fairly rapid perusal, as in a really illegible hand the context, rather than a minute study of individual characters, affords the readiest solution to the problems it presents.

The précis subject is more difficult. A number of printed letters and papers relating to some official matter is handed to the competitor. After reading these he must prepare an index giving the date of each document, the persons between whom it passed, and a brief and distinct statement of its subject-matter. He must then write a précis or summary, in the form of a continuous narrative, of the whole correspondence, so that a perusal of the précis would place anyone in possession of all the leading features of what had passed. The merits of such a summary, in official phraseology, are: "(*a*) to include all that is important in the correspondence; (*b*) to present this in a consecutive and readable shape, expressed as distinctly as possible, and as briefly as is compatible with distinctness."

The index should first be written, letter by letter, avoiding wordy, indirect phrasing, and taking care to omit from the summary mere side-issues and unimportant details in the documents. A "wrinkle" worth noting is that in official correspondence an admirable summary of a letter may often be found in the reply to it. Thus, the answer frequently runs: "Referring to your letter informing me that——" the rest of the sentence recapitulating in a few terse expressions the purport of the communication referred to. The student should keep a sharp look-out in the examination-room for such legitimate aids to indexing as may be furnished in this way by the correspondence itself. If the index be carefully done, the précis will become a fairly simple task.

Digesting Returns into Summaries. This quaintly named subject is a simple test of the clerkly qualities of neatness, care, and accuracy of calculation. Candidates are required to rule a form of statistical table like that given in their examination papers, to insert the various column headings, and finally to fill in the columns from printed particulars supplied. The task is never one of mere transcription, but involves always some rearrangement and mathematical work, such as the calculation of percentages, the substitution of kilogrammes for English weights, or the conversion of pounds sterling into marks or francs.

No special difficulty is presented by any of these exercises, yet in each case some preliminary practice is essential in order to complete the paper within the allotted time and to avoid mistakes; for as they are tests of exactness, every mistake, even though corrected, involves a loss of marks. Elementary as they are, the student cannot afford to neglect them. He may generally ensure sufficient practice in them by attending for a term or so one of the day or evening classes for the Civil Service to be found in almost every town.

"Tots." The arithmetic test in these competitions includes a special paper that merits the particular attention of candidates. This is the "tots" paper—a familiar feature of Civil Service examinations, and a simple trial of speed and precision. Candidates are given a printed set of exercises in addition, some having the figures arranged in vertical and others in horizontal columns. The *totals* of these figures have to be inserted in the form itself; hence the students' slang term "tots." Simple as the paper is, candidates who have not accustomed themselves to work accurately at top speed are certain to lose marks for errors or for failing to finish the exercise. On the other hand, steady practice will enable almost any student to ensure obtaining full marks.

The full list of examination subjects for Second Division clerkships, the maximum for each, and the actual marks obtained by the first and last successful candidates at a recent contest, are shown in the following table. It should be noticed that of the 11 papers only 7 may be taken, including not more than two languages; and further, that although no subject is obligatory, the competition is so keen that a candidate who took less than the full number permitted would not have the slightest chance of success. At this examination 1,197 students competed for only 70 places, an abnormally high proportion of candidates to vacancies.

EXAMINATION FOR SECOND DIVISION CLERKSHIPS

Order of Merit.	Service Marks.	Handwriting, Orthography, and Copying Manuscript.	Arithmetic.	English Composition.	Not more than Four to be Taken.								Total.
					Précis, Indexing, and Digest of Returns.	Bookkeeping and Shorthand.	Geography and English History.	Two only may be taken.			Elementary Mathematics.	Chemistry and Physics.	
								Latin.	French.	German.			
Max.	—	600	600	600	400	400	400	400	400	400	400	400	3400
1	–	618	510	450	—	—	353	280	308	—	306	—	2733
70	—	532	485	387	206	—	207	—	247	—	210	—	2364

Service Marks. A curious feature of these competitions is the allowance of special marks, proportionate to their term of service, to candidates who have been employed in Government offices as boy clerks. Thus 20 "service marks" are given for a year's service, 60 for two years, and the maximum of 120 is secured by three or more years' employment. These form very substantial additions to the examination total. For instance, in the competition to which our table of marks relates, no fewer than 16 successful candidates owed their good fortune to service marks.

Assistant Clerkships. The post of assistant clerk or abstractor, which has replaced the wretchedly paid and now obsolete rank of man copyist, offers few attractions beyond permanent employment and a slowly progressive salary. Its mechanical duties are repaid by a salary less than that of any other office on the permanent clerical staff. On the other hand, this grade is recruited wholly from the ranks of former boy clerks who have lacked the energy, ability, or fortune to secure better positions in the Second Division or elsewhere. The pay of assistant clerks, commencing at £55 a year, rises by £5 annually to £150, subject to a special certificate of efficiency at £100. They are allowed 14 days' annual leave, and after 10 years' service this becomes 18 days. They may be promoted to the Second Division, on the ground of special merit, after not less than six years' duty, and a considerable proportion of the total number are so promoted, in fact; but beyond this their prospects of advancement are of the scantiest.

Examinations. Examinations for assistant clerkships are held twice a year, usually in February and July. Candidates must be between 19 and 21 years of age on January 1st or July 1st of the year in which they compete, and must have actually served as boy clerks (or in the now almost extinct grade of boy copyists) for two years if their service commenced before the age of 17½, or for one year if it began after that age. The subjects of examination are five in number—namely:

1. English composition (including handwriting and spelling).
2. Arithmetic (to vulgar and decimal fractions).
3. Digesting returns.
4. Précis and indexing.
5. Shorthand and bookkeeping.

Competitors whose total marks do not indicate "a competent amount of general proficiency" are disqualified from receiving appointments. This standard has latterly been fixed at 1,000 marks in a maximum of 1,900.

At each examination about 100 vacancies are contested by three or four times that number of aspirants. As one-third of these, however, usually fail to attain the qualifying standard of marks, the *effective* competition is seldom much in excess of two candidates for each post. The great majority of assistant clerks are employed in London.

Poor as the appointments are in themselves, they are useful to ambitious and resolute young men who find it necessary, after serving as boy clerks, to earn a living wage while preparing for better positions. Among the present writer's official acquaintances, for instance, are two ex-abstractors, one of whom receives £550 a year, and the other £400 with a certain prospect of £650. But these are exceptional cases, and for men of average abilities there is a danger lest an assistant clerkship, adopted in the first instance as a merely temporary footing in the service, should be accepted at last as the "be-all and the end-all" of an official career.

LAUNDRY WORK

Utensils Required for Washing, Mangling, and Drying. Ironing Implements. The Preparation of Water, Borax, Soda, Soaps, etc.

By ALICE E. MARSHALL

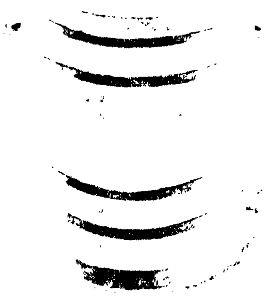
LAUNDRY work is a subject affecting every household, and ranking among the most important of the domestic sciences. The matter is one of no little importance to every home, directly or indirectly, and we shall, therefore, deal with it in the most thorough and practical way possible in such a course.

Laundry Utensils. Taking the various phases of laundry work in their natural sequence, we shall, in the first place, deal with the requisite utensils.

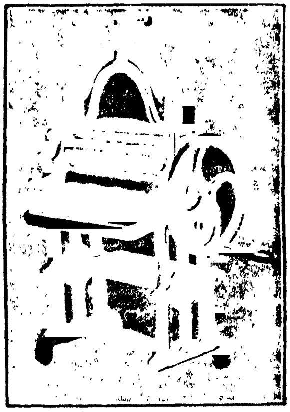
The Boiler or Copper. The boiler is generally a fixture, and is made of copper or iron, heated by gas or by a fire underneath. The former method of heating is coming more into general use, and is certainly cleanly and easily managed. The boiler must be kept perfectly clean and free from dust and dirt, being washed and dried well each time after use, otherwise there is a danger of the clothes becoming stained. A little washing-soda dissolved in hot water will remove any scum which may have adhered to the sides; or soap and powdered bath-brick may be used with like effect.

Washing Machines. Washing machines lighten the labour. They are of various kinds; one combining washing, wringing, and mangling is excellent, though somewhat expensive, costing about £5 [1].

1. WASHING, WRINGING, AND MANGLING MACHINE



3. DOLLY-TUB



2. MANGLE

The Mangle. This is useful for wringing and pressing clothes. A good make—we should not advise the purchase of any other—may be bought for £3. It saves a great deal of labour in wringing the clothes, and should, of course, be kept very clean. A cover should be thrown over it when it is not in use, and the screw must be loosened to relieve the pressure on the rollers; while the wheels need to be oiled occasionally in order to make it work easily [2].

The Wringer. A wringer is used sometimes in place of the mangle; this does not press the clothes, but only helps to remove the water. It may be bought as a separate article or fixed to a tub. The rollers are of indiarubber, and nothing very hot must be placed between them, or the rubber may crack. A cloth that has been dipped in an equal quantity of turpentine and water and then wrung out is useful for wiping the rollers occasionally. It helps to keep them soft and also removes any grease. A wringer costs about £1.

The Dolly-tub and "Posser." A dolly-tub [3] and "posser," or dolly-legs, will be needed for large things, such as sheets, which do not require much rubbing. The tub is made of wooden staves, bound together with iron bands. No nails are used in its manufacture, so care must be taken not to let it get dry, or it may fall to pieces. A little clean water should be left in the bottom when the tub is not in use. The "posser" is an American invention, and acts by suction. It is worked up and down in the tub, and draws the water through the clothes, thus freeing them from dirt.

The "dolly-legs" answer the same purpose, but are much heavier to use, and more unwieldy; with the tub, however, they save a great amount of labour which would otherwise be necessary in rubbing the clothes [4].

The Clothes-horse. A clothes-horse will be required, and a wooden rack is also desirable. The latter should be suspended from the ceiling, and will be found invaluable in drying and airing clothes. The wood of both "horse" and rack must be hard and well-seasoned, or it will stain the linen [5].

Lines and Pegs. These are necessary for outdoor drying; they should be brought indoors as soon as the clothes are dried and kept in a bag when not in use. They may be boiled in the copper occasionally. Pegs should be made entirely of wood, without a tin band, as the tin will sometimes cause a stain when the clothes are wet [6].

A Clothes Basket.

Zinc Baths. Two or three zinc baths for washing purposes are also needed; these do not rust, and they have the advantage of being much lighter to lift than those made of wood or earthenware.

Bowls. One or two papier-mâche bowls may be included in the outfit; they are particularly useful for small things, such as collars and laces, and though rather expensive—costing about 2s. 9d. each—they repay the outlay by being practically indestructible. With the mention of two wooden sticks for use in the boiler, we may leave the washing utensils.

4. DOLLY-LEGS 5. CLOTHES HORSE 6. PEGS 7. TABLE 8. SKIRT BOARD 9. SLEEVE BOARD 10. SHIRT BOARD

Ironing Implements. We have now to consider the "implements" used in ironing.

The Table. This is of the utmost importance; it should be fairly long, and not less than 3ft. wide, steady, and with an even surface. Anyone who has ironed on a table with one short leg, or with two or three cracks in the top knows the discomfort produced. It must not be too high, as pressure is required, and this is impossible when the arm has to be raised; neither should it be too low [7].

The Skirt, Sleeve, and Shirt Boards. These are aids in ironing, though they may be dispensed with. A local joiner will make any of them at a small cost. The skirt board is generally about 5 ft. long by 1½ ft. wide, narrowing a little at one end. This is inserted in the skirt, the ends of the board resting on two tables, a cloth or paper being placed on the floor underneath to prevent the skirt from getting soiled [8].

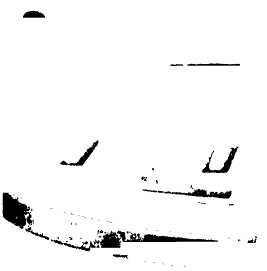
A sleeve board is similar in shape, but about the size of an ordinary shirt sleeve [9].

A shirt board is used in ironing the front of men's shirts, the usual size being about 16 in. long by 10 in. wide [10]. All the boards should be covered with felt or flannel, tacked together at the back of the board, and should then have clean white covers slipped over them, and tied on tightly with tapes. The ironing table must also be covered with felt or blanket, without any seams or joins, and over this a clean cotton cover, which should be tied down tightly at each corner, any "ruckling" being very undesirable whilst ironing. The felt may be bought for about 9d. per yard.

Irons. These are of various kinds—flat [11], box, gas, charcoal, etc. The two latter retain the heat longest, but some people object to the fumes which come from them. Flat irons are excellent to use if heated by gas, or on a closed stove; but it is almost impossible to keep them sufficiently clean for ironing starched things if heated in front of the fire. When the fire has to be used for heating purposes, the box-iron is preferable. A good fire must be kept up for the heaters. Irons should never be put on the fire, as this spoils the temper of the steel. Other irons used are polishing [12], goffering, crimping, etc., all of which are useful in giving a nice finish to the work, but are not absolutely necessary.

To clean the irons, wash them occasionally with soda and hot water, dry them well, rub them on a board sprinkled with bathbrick, and dust them thoroughly each time before use. When not in use, smear them with vaseline or mutton fat to prevent rust.

Materials. WATER. Among the materials used for laundry purposes water is the first consideration. This is, of course, of two kinds—hard and soft—and the degree of hardness may be determined by the amount of soap solution required in order to obtain a lather. Londoners are conscious of a difficulty in this respect. Rain-water is the purest form and the best for washing purposes; it dissolves soap readily, and is therefore economical. Work is much more quickly done when it is used, for as a cleansing agent the soap comes into action at once, and there is therefore no waste. In the country the rain-water can be collected for use; but in towns and cities the soot and organic matter render it useless for laundry purposes. Next in value to rain-water comes that from rivers and streams, and some river water is, indeed, as soft as rain-water. Spring and well water are the hardest. All hard water contains to a greater or lesser extent mineral salts, which it has taken up in its passage through the earth. Hard water has a peculiar effect on soap, which it curdles and makes into a substance known as "lime soap." This is easily recognised as the dirty scum which floats on the top of the water, and until sufficient soap has been added to overcome this hardness and form a lather, the water is unfit for washing purposes.



11. FLAT IRON

The softening of water may be brought about in different ways:

By exposure to the air, as in the case of reservoirs.

By boiling, when the lime becomes deposited.

By the addition of some softening agent, such as soda or borax.

The latter method is the one generally employed, as it is the easiest and the least expensive.

BORAX. This is much less harmful than soda, but is not so powerful in its action. One tablespoonful of powdered borax may be added to two gallons of hard water, but the borax must be previously dissolved in boiling water. Borax has the properties of:

Softening hard water, giving a gloss to linen, acting on grease.

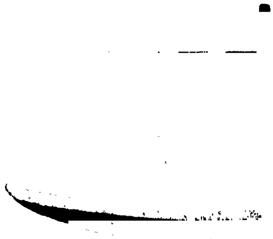
It does no harm to colour or material, and is inexpensive, costing about 2d. per lb.

SODA. This is a powerful alkali, chiefly obtained from common salt. It is a valuable cleansing agent, but requires to be used with great care, as it may destroy the colour and texture of any material with which it comes in contact. Soda should never be used for woollen clothes; it makes them yellow, hard, and less elastic. It should always be dissolved in boiling water before use. If a small piece settles on the clothes it causes brown stains to appear, which afterwards break into holes. For washing very dirty materials, such as oven cloths, it may be used with advantage, as it softens the water and acts on the dirt, assisting greatly in its removal. Add a piece of soda about the size of a walnut to two gallons of water, first dissolving the soda in boiling water. Soda should be kept in a covered jar in a dry place, or it will waste and lose its strength.

Washing powders should never be used for coloured materials.

SOAP. Soap is a chemical compound of fat and soda or potash, with the addition of resin. Soda is the alkali used in hard soap, and potash in soft soap. The latter is very powerful in its effects, and should be but rarely used.

The combination of fat with soda in soap neutralises the caustic effects of the latter, the two together, with the addition of resin, forming soap. Of this there are many varieties. The cheaper kinds generally contain an excess of alkali and water. The best for laundry purposes is the ordinary yellow soap. This should be bought from a reliable firm, in fairly large quantities, if possible, and should then be cut in convenient sized pieces, and stored away in a dry place, so that it may harden. New soap is very wasteful. The average cost of soap is about 3d. per lb., but it can be had cheaper if bought in large quantities.



12. POLISHING IRON

AMMONIA. In its liquid form ammonia is very useful in laundry work. It softens hard water, acts on grease, and is generally used in the washing of woollens. With melted soap and warm water it forms a soft lather; the garments are quickly cleansed, and their soft woollen nature is retained. Ammonia, being of a volatile nature, should be kept in a tightly-corked bottle, and be labelled "Poison." Before washing-day, the stores should be examined to see that all requisites are at hand.

BLUE. This will be required to tint the clothes.

SALT and VINEGAR for coloured materials.

STARCH, WAX, and TURPENTINE for stiffening purposes.

GUM ARABIC to stiffen silks, etc.

MELTED SOAP for flannels and prints, etc. This should be prepared by shredding some soap (the odd pieces can be used up) into a pan, covering it with cold water, and allowing it to dissolve slowly by the side of the fire; then pour it into a jar, and it is ready for use.

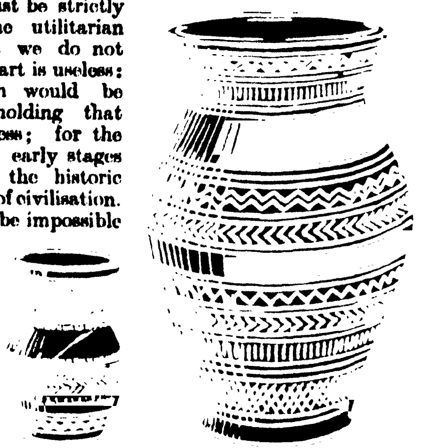
A SHORT HISTORY OF ART

A Survey of the Beginnings and Evolution of Art through all Ages: Stone and Bronze Ages, and the Influence of Religion on Early Art

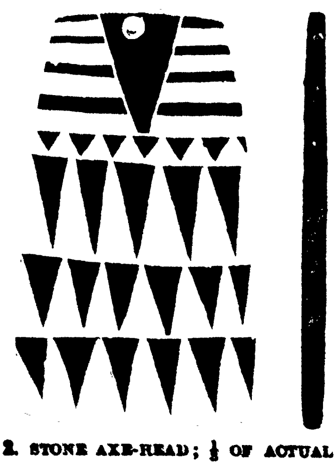
By P. G. KONODY

THE origin of art is shrouded in the impenetrable veil of the unknown past. To trace the earliest manifestations of the artistic instinct belongs more to the sphere of the geologist than to that of the historian; and it is indeed difficult, if not impossible, to define the beginning of the artistic functions of prehistoric man. But it seems fairly obvious that the exercise of the artistic function must be strictly separated from the utilitarian principle. By this we do not mean to imply that art is useless: to maintain which would be equivalent to upholding that civilisation is useless; for the history of art, in its early stages more than during the historic period, is the history of civilisation.



1. DRINKING CUPS (*British Museum*)

Civilisation would be impossible without the establishment of human communities, and art is essentially a manifestation of the social instinct which leads to the formation of communities. When the cave-dweller of Perigord and of the Pyrenees chipped his axes and spearheads out of flint, his object was entirely utilitarian; but when he tried to give them as symmetrical a shape as was in his power [2], and began to decorate them with simple ornaments—more so still when he painted his body with ochre—his motives were of a social character: he did this to please the eye of his fellow-man; and here we have the first manifestations of art. When prehistoric man at a later period shaped his first earthenware vessels, his object was utilitarian; when he adorned them with zig-zag lines and patterns scratched into the clay, he was actuated by the art instinct.



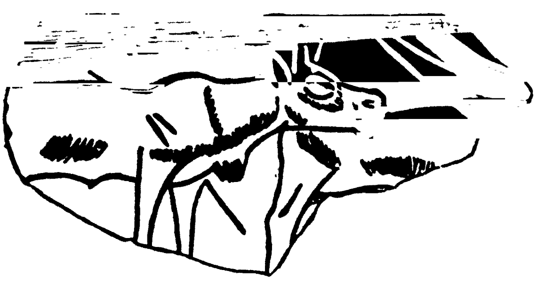
2. STONE AXE-HEAD; ½ OF ACTUAL SIZE (*British Museum*)

The Beginnings of Art. There can be little doubt that personal adornment gave the man of the Quaternary period his first scope for the exercise of art, if we use the word in its widest sense. He wanted to increase his personal attractiveness, and what in the lower stages of organic life is wrought by sexual selection had thus become a conscious function of the human mind. And considering the matter from this point of view, we lose again the demarcation line between the utilitarian and the artistic principles.

Where art is first met in an unmistakable and clear form, it reveals to us a comparatively high stage of development which can only have been the result of slow evolution. The art of a nation has to pass through the same stages that can be observed in the first attempts of a child; but the wonderfully realistic rendering of animals in motion, incised with flint instruments on reindeer bones, found in the caves of prehistoric man in England and France, and on the walls of these caves [see page 2256], have little in common with the childish stuttering of an infant's first pictorial attempts. They are rather the scarce remains of a primitive civilisation, dating 12,000 to 14,000 years back, which was followed by an age of decadence setting in approximately with the disappearance of the reindeer from this region [3-6].

So faultless are some of these early representations of animals as regards clear delineation, expression of varied movement, bold simplification, suppression of detail, and grasp of all that is really essential, that these early attempts will lose nothing by being placed beside the sketches of the most competent and advanced of modern artists. And as the scratching of these outlines on bone mark the first attempts at drawing, so in the filling in of the contour with earth colours may be discovered the first stage of the art of painting.

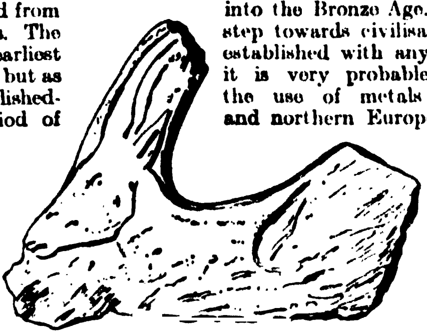
The child, in its attempts at drawing passes from merely ornamental line to animal and, finally, to human forms. The artist of the Quaternary period never passed beyond the second stage. He would depict animals on his implements, scratch them upon the walls of his cave dwellings, incise them on reindeer bones, and carve them in bone and horn; but he never advanced to the representation of the human figure. This achievement was left to a later civilisation, which had its origin in the East—in the valleys of the Nile and the Euphrates, in India and in China, and of which we shall have to speak later.



3. BONE ENGRAVING OF REINDEER, LA MADELAINE

(*British Museum*)

The Stone Age. If what may be termed "pictorial art" appears to us in an advanced form in these remote ages, monumental sculpture and architecture can be traced from their very earliest beginnings. The simplest and earliest form (earliest not as regards actual date, but as regards development; the polished-stone age and bronze period of Northern Europe coincide with the flourishing of a very high civilisation in Egypt, which had its prehistoric period several thousand years earlier) is the artificially raised burial mound, or tumulus, or a mighty rude block of stone, or menhir, erected in memory of some fallen hero or great event. The single stone block can scarcely be described as a work of art, though at times it was ornamented with geometrical designs, and even carved into an approximate semblance of a human being; but the artistic intention becomes clearly perceptible when the stones are planted into the ground in rows at regular intervals to form a pattern, as can be seen at Carnac in Brittany. The table-like altars at Stonehenge mark a further development [7]. Flat stone blocks are laid on to two to four upright stone supports of equal height, which have the function of walls or pillars, as the case may be, and thus for the first time introduce an architectural motif. To a little later period belong the lacustrine dwellings, about 3500 B.C. These were wooden buildings erected on piles driven into the mud at the shores of the Swiss and French lakes—the first buildings, properly speaking, and a great step forward from the cave dwellings of the Quaternary races. Now polished stone had taken the place of chipped flint, and rude pottery was extensively used; but no specimens of "pictorial" art, like the incised bones of Perigord, have been found among the remains buried in the mud of the lakes [1].



4. IBEX HEAD; ⅔ OF ACTUAL SIZE

(*British Museum*)

The Bronze Age. The Stone Age passed into the Bronze Age. Exactly when this great step towards civilisation was taken cannot be established with any degree of certainty; but it is very probable that the knowledge of the use of metals was brought to central and northern Europe by the Phœnicians, and that the lacustrine dwellers shaped ornaments of gold and objects of copper before they had learnt how to produce bronze by fusing copper and tin. Innumerable articles for personal adornment and for daily use that have been brought to the light from the lake dwellings and burial places of Great Britain, France, Germany, Switzerland, and Scandinavia have a distinct claim to be considered as works of art, since many of them are wrought into exquisite shapes, and, moreover, profusely decorated with ornamental design—spiral, circular and curved lines, in faultlessly symmetrical arrangement. The ornamentation is either incised or welded on to the body of the object. But with all his skill of craftsmanship, taste in design and inventiveness, man of the bronze period never attained to the artistry of that much earlier period to which belong the wonderful representations of animals carved on bone with rude flint implements by the contemporary of the mammoth and the reindeer [8]. It is extraordinary that he did not rise to the

(*British Museum*)

7. STONEHENGE *Valentine*

imitation of the forms of nature, and restricted himself to the abstract invention of ornament. The reason for it may perhaps be found in some religious superstition which forbade the representation of man and beast and plant ; perhaps some severe law like that of the ancient Jews, which placed God's creation beyond the pale of art.

Influence of Religion on Art. Altogether it is impossible to lay too much stress on the influence of religion on art from the dawn of civilisation to the end of the Middle Ages. Religious belief, the worship of the dead, and of the mysterious powers that rule human life, the desire to give tangible expression to the vague mysteries of religion, to create symbols for the idea of the invisible forces that shape human destinies, were ever the most powerful stimulants for the creation of art. Perhaps the very scratchings on reindeer bones and on the walls of the caves owed their origin to some religious superstition. The dolmens and menhirs, the whole early pictorial and plastic art of Egypt, the grotesque images carved in stone by the South Sea Islanders, and by the ancient Peruvians and Mexicans, are inspired by the religious beliefs of their makers. In fact, all early manifestations of art owe their origin to religion and to superstition—to the desire to pacify the invisible powers and to honour the dead, or rather to secure their intercession with the dreaded powers. And the first expressions of the artistic instinct are akin in all parts of the globe. They can be traced among the Celts and Scandinavians, and the South Sea Islanders, on the shores of the Mississippi and in the heart of Asia, though, of course, the dawning of the artistic intellect appeared at different periods in the different parts of the world. Thus the civilisation, or rather the art, found by the Spanish conquerors in the lands of the Incas and the Aztecs was in many respects similar to that of the Egyptians 3,000 years before Christ ; and the present day aborigines of some Polynesian islands have not yet achieved the civilisation of the Celtic period in Europe. It is for this reason that the introductory chapter of our survey of the world's art in its logical sequence takes us to Europe at a time about 1000 B.C., whilst Egypt had already passed through the great period of her civilisation. In northern Europe we are still in the primitive, prehistoric age, whilst in the East, history has been made, and mighty Empires have risen and fallen into decay.

ADJECTIVES

Adjectives agree in gender and number with the nouns they qualify.

Adjectives are of two classes: those that have a termination for each gender, as: *blanco*, white, fem. *blanca* ; and those that have only one termination for both genders, as : *grande*, great ; *vil*, vile.

Formation of the Feminine. All adjectives ending in *o* change the *o* to *a* in the feminine—example: *hermoso*, beautiful, fem. *hermosa*.

As a general rule adjectives ending in a consonant have the same ending in both genders, as: *un hombre feliz*, a happy man ; *una mujer feliz*, a happy woman.

The following adjectives ending in a consonant are exceptions to this rule and take an *a* in the feminine.

Adjectives ending in *on* or *an*, as : *holgazan*, lazy, fem. *holgazana* : *bribon*, thievish, fem. *bribona*.

Adjectives ending in *or*, as : *traidor*, treacherous, fem. *traidora* ; except : *inferior*, inferior ; *superior*, superior ; *mayor*, bigger ; *mejor*, better ; *peor*, worse ; *anterior*, anterior ; *posterior*, poster or ; and *ulterior*, ulterior ; which are invariable.

Adjectives of nationality take an *a* in the feminine ; those ending in *a* are the same in both genders.

inglés, English, *inglesa*
español, Spanish, *española*
frances, French, *francesa*
persa, Persian, *persa*

NOTE. Adjectives of nationality do not require a capital letter in Spanish.

Formation of the Plural. Adjectives, ending in an unaccented vowel take an *s* in the plural.

mas. *feo*, ugly, pl. *feos*
fem. *fea* pl. *feas*

Adjectives ending in accented vowels or consonants take *es* in the plural ; those ending in *z* change the *z* into *ces*, thus : *cortes*, courteous, pl. *corteses* ; *carmesi*, crimson, pl. *carmesies* ; *feliz*, happy, pl. *felices*.

General Remarks on Adjectives. Almost any adjective in Spanish can be used as a noun, and become subject to all the rules governing nouns, as : *traidor*, treacherous ; *un traidor*, a traitor ; *inglés*, English ; *un inglés*, an Englishman.

The following eight adjectives lose the final *o* in the singular before a musculine substantive : *Alguno*, some ; *bueno*, good ; *malo*, bad ; *uno*, one ; *primero*, first ; *tercero*, third ; *postrero*, last ; thus : *un buen amo*, a good master ; *el primer hombre*, the first man ; *un rey*, one king ; *algun dia*, some day. The adjective *santo* (holy) loses the final syllable before the names of all saints except Saint Dominic, Saint Thomas, and Saint Toribius, as : *San Pedro*, Saint Peter ; *San Pablo*, Saint Paul ; *Santo Tomas*, or *Tomé*, Saint Thomas ; *Santo Domingo*, Saint Dominic. When the island of St. Thomas is meant the last syllable is not retained.

Ciento, a hundred, loses the last syllable before substantives and adjectives, but retains it in every other case, as : *cien hombres*, a hundred men ; *ciento y uno*, a hundred and one.

Grande, great, when it signifies excellence, loses the last syllable and precedes the noun, unless the latter begins with a vowel, as: *un gran poeta*, a great poet ; *una grande amistad*, a great friendship. When it signifies size or extent, it is placed after the noun, thus; *una mesa grande*, a large table ; *un campo grande*, a large field.

Vocabulary	**Vocabulario**
The cows	Las vacas
The bulls	Los toros
The heifers, calves	Las terneras
The horses	Los caballos
The mares	Las yeguas
The colt	El potro

splendidos . . . .

PROSE EXTRACT IV.

From "Don Quijote," by Miguel de Cervantes.

Don Quixote and the Puppet-show.	Don Quijote y el retablo.
Don Quixote, seeing such a swarm of Moors and hearing such a clamour, thought it would be well to aid	Viendo y oyendo pues tanta morisma y tanto estruendo D. Quijote, parecióle ser bien dar ayuda á los

the fugitives, and starting up, he cried aloud, "It shall never be said while I live that I suffered villainy to be done in my presence to so famous a knight and so bold a lover as Don Gayferos. Forbear your pursuit and persecution, you base-born curs or you will have me to deal with!" So saying he drew his sword and with one spring got to the show and began to rain his blows upon the Moorish puppets with headlong fury, overthrowing some, beheading others maiming this, and demolishing that. Among others he delivered such an up and down stroke that if Master Peter had not ducked and crouched down, he would have sliced a piece off his head as easily as if it had been made of marchpane. Then Master Peter cried out, "Hold, hold, your worship! Think what you are about, Don Quixote. These are not real Moors that you overthrow and hack and kill, but pasteboard puppets. Sinner that I am! you are spoiling and destroying all my worldly goods." But Don Quixote did not cease cutting and slashing till in less than two credos he brought the whole show to the ground, with all the strings cut to pieces, and all the puppets smashed to atoms, King Marsilius wounded, and the Emperor Charlemagne's head and crown cleft in two. The audience fled in confusion; the monkey escaped over the tiles of the inn; the cousin was frightened, the page terrified, and even Sancho Panza struck with fear and wonder, for, as he swore when the hurricane was over, he had never seen his master in such a blind rage before. The general rout of the puppets being over, Don Quixote calmed down a little and said, "I wish I had here before me all those who do not and will not believe in the good done by knights-errant in the world; for see, if I had not been there, what would have become of good Don Gayferos and fair Melisandra? These ruffians would have caught them long ago and used them ill. Therefore long live knight-errantry above everything on earth!" "Long let it live," quoth Master Peter at that moment in a doleful voice, "and let me die, for I am so unfortunate that I can say with King Roderick, 'But yesterday I was lord of Spain and now I have not a turret to call my own.'"

que huian, y levantándose en pié, en voz alta dijo: no consentiré yo que en mis dias y en mi presencia se le haga superchería á tan famoso caballero y á tan atrevido enamorado como D. Gaiféros: deteneos mal nacida canalla, no le sigais ni persigáis; si no, commigo sois en la batalla; y diciendo y haciendo desenvainó la espada, y de un brinco se puso junto al retablo, y con acelarada y nunca vista furia comenzó á llover cuchilladas sobre la titerera morisma, derribando á unos, descabezando á otros, estropeando á este, destrozando á aquel, y entre otros muchos tiró un altibajo tal que si maese Pedro no se abaja, se encoge y agazapa, le cercenera la cabeza con mas facilidad que si fuera hecha de masa de mazapan. Daba voces maese Pedro diciendo: deténgase vuesa merced, señor D. Quijote, y advierta que estos que derriba, destroza y mata no son verdaderos moros, sino unas figurillas de pasta: mire; pecador de mi! que me destruye y echa á perder toda mi hacienda. Mas no por esto dejaba de menudear D. Quijote cuchilladas, mandobles, tagos y reveses como llovidos. Finalmente en menos de dos credos dió con todo el retablo en el suelo, hechos pedazos y desmenuzadas todas sus jarcias y figuras; el rey Marsilio mal herido y el emperador Carlo Magno partida la corona y la cabeza en dos partes. Alborotóse el senado de los oyentes, huyóse el mono por los tejados de la venta temió el primo, acobardóse el page y hasta el mismo Sancho Panza tuvo pavor grandisimo; como el juró despues de pasada la borrasca jamas habia visto á su señor con tan desatinada cólera. Hecho pues el general destrozo del retablo, sosegóse un poco D. Quijote, y dijo: quisiera yo tener aquí delante en este punto todos aquellos que no creen ni quieren creer de cuánto provecho sean en el mundo los caballeros andantes: miren si no me hallára yo aquí presente, que fuera del buen D. Gaiféros y de la hermosa Melisandra; á buen seguro que esta fuera ya la hora que los hubieran alcanzado estos canes y les hubieran hecho algun desaguisado. En resolucion viva la andante caballeria sobre cuantas cosas hoy viven en la tierra. Viva en hora buena, dijo á esta sazon con voz enfermiza maese Pedro, y muera yo, pues soy tan desdichado que puedo decir con el rey D. Rodrigo: Ayer fui señor de España y hoy no tengo una almena que pueda decir que es mia.

Miguel de Cervantes, (1547 to 1616), the greatest genius of Spain, had written many poems, plays, and tales in prose, and was fifty-seven before he produced "Don Quixote," the masterpiece which made his name immortal.

Miguel de Cervantes (1547–1616), el mas grande genio de España, escribió muchos poemas, comedias, ó historias en prosa, tenia cincuenta y siete años cuando publicó Don Quijote, la obra maestra que hizo su nombre inmortal.

KEY TO EXERCISE III.

1. *El* cometa luce de noche.
2. *Los* niños vuelan *las* cometas.
3. *El* cólera es peligroso.
4. *La* cólera es un pecado.
5. El *corte* de este traje es bueno.
6. *La* corte de St. James.
7. *El* moral tiene mucha fruta.
8. *La* moral de las naciones difieren.

9. *El* pendiente es de brillantes.
10. *La* pendiente de esta cuesta es grande.
11. Se saluda con la cabeza.
12. Los ojos son para ver, y la nariz para *oler*.
13. La boca es para comer, y los dientes para masticar.
14. Las manos son para tocar las uñas para arañar.
15. Los piés son para andar.
16. Ir de paseo.
17. El perro se pelea con el gato.
18. Las sillas del comedor son verdes.
19. El carnicero trajo la carne, y el panadero el pan.
20. La cocinera guisa bien.
21. El portero abre la puerta de la casa.
22. El juez juzga el pleito y el abogado lo defiende.
23. El magistrado administra la justicia.
24. Pleitear es costoso.
25. Se puede apelar cuando se pierde un pleito.

EXERCISE XI.

ON THE VERBS *Èssere* AND *Avere* (*continued*).

1. Se io avessi. 2. Se non avessi? 3. Che egli abbia. 4. Che egli sia. 5. Che voi siate. 6. Se noi non fossimo? 7. Se io non fossi. 8. Essi sarèbbero. 9. Essi avrèbbero avuto. 10. Se avessi avuto tempo, sarei venuto. 11. Se fossi . . . avrei . . . 12. Egli sarebbe . . . se essi non fòssero stati . . . 13. Avendo tempo . . . sarò . . . 14. Essi son poveri, ma sarèbbero ricchi se avèssero avuto . . . 15. Aver. 16. Di aver. 17. Abbiate pazienza. 18. Siate buoni.

NOTE. (i.) The infinitives *èssere* and *avere*, and their third persons plural *sono, erano, furono, avevano,* etc., are often contracted into *esser, aver, son, eran, furon,* etc. *Son* stands also for *sono,* first person singular.

NOTE. (ii.) *Se,* if, must never be used with the conditional; say, *Se io avessi,* and not: *se io avrei*; *se noi fossimo,* and not *se noi saremmo.*

OBSERVATIONS ON THE PLURAL OF NOUNS.

1. All nouns ending in *ca* and *ga* form their plural in *che* and *ghe,* if feminine, and in *chi* and *ghi* if masculine—*e.g., la barca* (*bàhrcah*), the boat, *le barche*; *la paga* (*pàhgah*), the pay, *le paghe*; *il monarca* (*monàhr-cah*), the monarch, *i monarchi*; *il collega* (*collèhgah*), the colleague, *i colleghi.*

2. Feminine nouns in *cia* and *gia* end in the plural in *ce* and *ge,* if the *i* is not accented—*e.g., piòggia* (*pee-ò-dgee-ah*), rain, *piogge*; *bilància* (*beelàhn-chee-ah*), scales, *bilance.* But if the tonic accent falls on the *i* of *cia* and *gia,* the nouns follow the general rule and change the *a* into *e* in the plural—*e.g., bugìa* (*boo-dgeè-ah*) lie, *bugìe*; *farmacìa* (*fahr-mah-cheè-ah*), pharmacy, *farmacìe.*

NOTE. Whenever the omission of the *i* might cause ambiguity the plural of such nouns may end in *cie* and *gie*—*e.g., camicia* (shirt), *audàcia* (audacity), and similar words, make in the plural *camicie, audàcie,* in order not to be confounded with *càmice* (vestment), *audàce,* audacious (adj.).

3. Nouns in *co* and *go* form their plural, some in *ci* and *gi,* and some in *chi* and *ghi.*

(*a*) Nouns of two syllables end in the plural in *chi* and *ghi,* as: *cuoco* (*koo-òco*), cook, *cuochi*; *fuoco* (*foo-òco*), fire, *fuochi*; *ago* (needle), *aghi*; *borgo* (borough), *borghi*; *luogo* (place), *luoghi,* etc. Exceptions: *il porco* (the pig), *i porci*; *Greco* (Greek), *Greci.*

(*b*) Nouns of more than two syllables in *co* end in the plural in *ci,* as: *amico, amici*; *nemico, nemici*; *medico, medici*; *Austrìaco, Austrìaci.*

Exceptions: *antico* (*ahnteèco*), ancient, *antichi*; *mànico* (*màh-neeco*), handle, *manichi*; *vàlico* (*vah-leeco*), passage, *valichi*; *rammàrico* (regret) *rammàrichi*; *càrico* (loaded), *càrichi*; *caduco* (frail, failing), *caduchi*; *pudico* (*poodeè-co*), chaste, *pudichi*; *opaco* (opaque), *opachi*; *ubbriaco* (*oobree-àhco*), drunken, *ubbriachi*; *dimèntico* (forgetful), *dimèntichi.* All nouns having a consonant before the syllable *co* end in the plural in *chi,* as: *Tedesco* (German), *Tedeschi*; *Polacco, Polacchi.*

(*c*) Nouns of more than two syllables in *go* end in the plural in *ghi,* as: *albergo* (inn, hotel), *alberghi*; *catàlogo* (catalogue), *catàloghi.* Exceptions: *teologo, teologi*; *geologo, geologi,* and a very few more, all of Greek origin.

4. Nouns ending in *io* simply drop the *o* in the plural, if the *i* is not accented, as: *bàcio* (*bàh-chee-o*), kiss, *baci*; *giudizio* (*dgee-oodeè-tzee-o*), judgment, *giudizi.*

But they have two *i's* in the plural, when they might be confounded with other nouns similarly spelt and of different meaning—*e.g., princìpio* (*preen-cheè-peeo*), principle, *augùrio* (*ahoogoòreeo*), good wish, make in the plural *princìpii, augùrii,* in order not to be confounded with *prìncipi* (princes), *àuguri* (diviners). But, as we have already seen, such nouns are also distinguished by the grave accent: *princìpi, augùri.*

If the tonic accent falls on the *i* of words ending in *io,* they follow the general rule, and change the *o* into *i* in the plural, thus ending in *ii,* as: *zìo, zii, addìo* (good-bye), *addii.*

NOTE. The *h* inserted between the *c* and *g* and the terminations of the plurals of the nouns ending in *ca* and *ga,* and some of those ending in *co* and *go,* is not an irregularity. It is simply an orthographic sign employed to indicate that the letters *c* and *g* preserve the *hard sound* of the singular, otherwise these letters would be pronounced *cheh*, *dgeh*, *chee*, *dgee*. The *i* of the nouns in *cia* and *gia* is also an orthographic sign, used to give the *c* and *g* a *soft sound* before *a*. In the plural the *i* is dropped, because it is no longer necessary, the sound of *c* and *g* being *soft* before the *e*.

ESERCIZIO DI LETTURA

(Manzoni, *I Promessi Sposi*, Cap. XI.).

Una delle più gran consolazioni(1) di questa vita(2) è l'amicizia(3); e una delle consolazioni dell' amicizia è quell' avere a cui(4) confidare(5) un segreto. Ora(6), gli amici non sono due a due(7), come(8) gli sposi; ognuno(9), generalmente parlando(10) ne ha più d'uno(11): il che(12) forma una catena(13), di cui nessuno potrebbe trovar la fine(14). Quando dunque un amico si procura(15) quella consolazione di deporre(16) un segreto nel seno d'un altro, dà a costui la voglia di procurarsi(17) la stessa consolazione anche lui. Lo(18) prega, è vero(19), di non dir nulla a nessuno(20); e una tal(21) condizione, chi la prendesse nel senso rigoroso delle parole(22), troncherebbe(23) immediatamente il corso delle consolazioni. (*Continued.*)

NOTES. (Expressions have been chosen which shall correspond as nearly as possible with the exact meaning of the Italian words). 1. Of the greatest consolations. 2. Life. 3. Friendship. 4. To whom. 5. Entrust. 6. Now. 7. In pairs. 8. As. 9. Everyone. 10. Generally speaking. 11. Has more than one of them (*ne*). 12. Which (referred to the preceding sentence). 13. Chain. 14. Of which no one can find the end. 15. Procures himself. 16. Of depositing. 17. Gives him an inclination to procure himself. 18. Him. 19. It is true. 20. Not to tell anything to anyone. 21. Such. 22. Were any one to take it in the rigorous sense of the words. 23. Would cut short.

CONVERSAZIONE.

Buon giorno (good morning), signore; siete già di ritorno (back) a Londra?

Sì, perchè mia sorella è stata ammalata (ill); ma sarò a Parigi fra due o tre giorni.

Vi sono molti Inglesi nel vostro albergo?

No, ma vi sono molti Tedeschi. Vi sono anche i due mèdici italiani e le due signorine polacche, che abbiamo conosciute a teatro l'inverno scorso (last winter).

Sono comodi gli alberghi in Francia?

Le càmere (bed-room) sono ordinariamente molto larghe e il servizio è eccellente.

Che cosa (what) avete comprato?

Abbiamo comprato due paia di guanti (gloves), un cappello e delle camicie. Le nostre amiche non hanno comprato niente (nothing), perchè non avèvano danaro.

Che cosa avrèbbero comprato se avèssero avuto danaro?

Esse avèvano intenzione di comprare (to buy) un anello.

Se avete sete, lì c'è (there is) dell' acqua (water) e una bottiglia di vino.

Gràzie.

KEY TO EXERCISE IX.

In our garden we have fruit[s] and flowers. The boys have gathered some flowers for the visitors, and they have had [got] some money. The dresses of the ladies are in the wardrobe. Your hands are dirty. The workmen will have their wages (the pay) every week. The lamps are on the table. In the schools, in the churches, in the theatres, they have collected money for those damaged by the earthquake. The inhabitants are without shelter. The soldiers had orders to go to the damaged cities. There are many victims. The pupils will have paper, pencils, and pens. The officers have given (gave) a dinner in honour of the English fleet; there have been (were) many toasts. They have opened a school for the deaf and dumb. We have many bottles of wine, but we have no corkscrew. We have not written the letters, because we have not found the addresses. When you [will] have written the answers you will be at liberty to go.

KEY TO EXERCISE X.

1. The hand has five fingers. 2. The laughter of the boys. 3. A waggon drawn by two pairs of oxen. 4. The two right wings of the enemy's army were of ten thousand men each. 5. We shall be cold this evening, because we have no firewood in the house. 6. We have bought some eggs and some bread because we are hungry. 7. I am very cold; I am chilled to the bone (literally, I have chills in my bones). 8. Where are the scissors? There they are, on the table, together with the spectacles. 9. The peasants have brought fruit[s] and flowers for the silver wedding of their masters. 10. On the death of her aunt that girl will have several thousands a year.

By Louis A. Barbé, B.A.

IMPERFECT INDICATIVE TENSE

The endings of the imperfect of the indicative are the same in all verbs. They are *-ais*, *-ais*, *-ait*, *-ions*, *-iez*, *-aient*. This tense is used to express customary or repeated action, and, in narratives, to describe accompanying circumstances, state, or condition:

Autrefois je le rencontrais tous les jours, Formerly I used [to] meet him every day.

Il ventait, il pleuvait, le temps était très rude, The wind [was] blowing, it [was] raining, the weather was very rough.

Un bon feu flambait dans la cheminée, A good fire was blazing in the hearth.

Imperfect Indicative of Avoir:

I had, used to have:

j'avais, *nous avions*
tu avais *vous aviez*
il avait *ils avaient*
elle avait *elles avaient*

Imperfect Indicative of Être:

I was, used to be:

j'étais *nous étions*
tu étais *vous étiez*
il était *ils étaient*
elle était *elles étaient*

Imperfect Indicative of Donner:

I used to give, was giving:

je donnais *il donnait* *nous donnions*
tu donnais *elle donnait* *vous donniez*
ils donnaient *elles donnaient*

In expressions of time *il y a* is equivalent to the English "ago." It always precedes the words that indicate the length of time:

Il y a dix minutes, Ten minutes ago.
Il y a trois ans, Three years ago.

Exercise XIX.

Vocabulary

aile (f.), wing
le bec, beak
le biscuit, biscuit
le bouvreuil, bullfinch
le bruit, noise
la cage, cage
la chambre à coucher, bed-room
le chènevis, hemp-seed
les cheveux (m.), hair
le compagnon, companion
la connaissance, acquaintance
le cou, neck
la croisée, window
le danger, danger
le déjeuner, breakfast
le dos, back
épaule (f.), shoulder
expression (f.), expression
la fin, end
le fumier, heap of manure
le gazouillement, chirp
la gorge, throat
le goût, taste
la griffe, claw
l'histoire, (f.), story
l'humeur (f.), temper
intrus (m.), intruder
la journée, day (day-long)
le lendemain, next day
la main, hand
la miette, crumb
le moineau, sparrow
le mois, month
oiseau (m.), bird
le pain, bread
le pas, footstep, pace
le plumage, plumage
la poitrine, breast
la poule, hen
la prison, prison
la provision, stock
le rebord, edge, sill
le rouge-gorge, robin
le secours, help
le séjour, stay
la soirée, evening
le son, sound, note
le sucre, sugar
la tête, head
la voix, voice
la vue, sight

aimable, kind, kindly
ample, ample
brun, brown
content, pleased
doux, sweet, gentle
dur, hard
entre-baillé, slightly open
épais, thick
gai, cheery
gentil, nice, amiable
hargneux, snappish, surly
heureux, happy
intolérant, intolerant
jaune, yellow
lustré, glossy
moelleux, soft
noir, black
rouge, red
rude, rough
tacheté, spotted, speckled
triste, sad
varié, varied

amuser, to amuse
apporter, to bring
attaquer, to attack
attirer, to attract
becqueter, to peck
caresser, to pet, caress
charmer, to delight
chasser, to drive off
demander, to ask for
donner, to give
ébouriffer, to rumple, disorder
égayer, to enliven, cheer
enjamber, to step over
entourer, to surround
éveiller, to waken
fâcher, to anger
filer, to warble, trill
flamber, to blaze
gratter, to scratch, scrape
houspiller, to worry, to mob
inquiéter, to trouble
passer, to spend, pass
rentrer, to come in, return
saluer, to salute
sauter, to jump
soigner, to tend
tirer, to draw away, rescue
tourner, to turn
trouver, to find
vagabonder, to roam about
voler, to fly
voleter, to flutter

endormi, asleep
entendu, heard
fait, made
mort, dead
ouvert, open
vu, seen

à travers, through
autour de, about, around
bien (before adjectives), very
dehors, outside
ne . . . jamais, never
même, even
pendant que, whilst
presque, almost, nearly
quelquefois, sometimes
souvent, often
trop tard, too late
vite, quickly

Translate into French.

You ask me for the story of my bullfinch; here it is. A friend of mine has a house in the country. I sometimes spend the winter at his house. *I* like the country in winter; *you* like the town better. Each one (to) his taste. Two years ago I (have) made a stay of several months there, and whilst I was there I made the acquaintance of a bullfinch. He was a little bigger than a sparrow; his beak was thick, black, and hard; his little eyes had a kindly expression. I have never seen any plumage more beautiful, more glossy than his. His head was black and his breast almost as red as a robin's. His wings were spotted with (*de*) red also. His voice was sweet, and I have never heard any notes softer and more varied than those which he warbled. He cheered me and delighted me. I tended him, I petted him. When my breakfast was brought me, I gave him his also. I gave him all that he liked most; crumbs of bread, little pieces of biscuit and of sugar. He pecked them in my hand. We were very good friends, he and I. The winter was rough, but that did not trouble us. A good fire blazed in the hearth. We had an ample stock, I, of books, he, of hemp-seed. We were both happy; we were pleased with (*de*) each other. For birds, a cage is often only a prison. *His* was only a bedroom. The door of it was always open. Almost all day long he roamed about through the room. It did not belong more to me than to him. Sometimes he fluttered round me; he jumped on my shoulder, and even on my head; he rumpled my hair. That amused him, and me too. He was a cheery companion. I have never had any nicer than that one. I did not spend all my evenings with him. When I returned I used to find him asleep. He had his head under his wing. The noise of my footsteps used to wake him. He used to salute me with (*par*) a little chirp. Next day I was awakened by my little friend. But the end of my story is something very sad. One day the bullfinch finds the window slightly opened. Whilst I have my back turned, he passes quickly outside. Twenty paces from the house, there is a large heap of manure, yellow and black, where half a dozen hens scratch and peck. It is nothing fine, but it is something interesting for him. From the ledge of the window he flies on to the manure heap. But he is an intruder. The hens have an (the) intolerant and surly temper. The sight of the bullfinch angers them. They surround him, worry him, attack him. The noise attracts me. I look through the window. It is he; it is my poor bullfinch. I step over the window; I go to the help of my little companion. I drive the hens away; I rescue him from their claws. It is too late. My poor little companion is dead.

KEY TO EXERCISE XVIII.

1. Où peut-on être mieux qu'au sein de sa famille ?
2. On nous a dit de vous donner ceci.
3. On obéit à ce roi parce qu'on le craint, mais personne ne l'aime.
4. On dit qu'il est très riche.
5. Quiconque a fait cela est un méchant homme.
6. Si quelqu'un vous parle, répondez-lui.
7. Je ne connais personne ici et personne ne me connaît.
8. Si vous avez encore de ces poires, donnez-m'en quelques-unes.
9. Quelqu'un (on) demande à vous parler.
10. Nous avons appris quelque chose de très intéressant.
11. Je connais quelqu'un de plus puissant que lui.
12. Nous n'avons pas fait grand'chose de bon aujourd'hui.
13. Il n'y a rien de plus agréable que de voyager à pied.
14. Y a-t-il rien de plus surprenant que cette histoire ?
15. Chacun de mes amis a remporté plusieurs prix.
16. Faites à autrui ce que vous voudriez que l'on vous fît.
17. J'ai parlé à l'un et à l'autre.
18. Les vrais chrétiens ne médisent pas les uns des autres.

GERMAN

Continued from page 2362

By P. G. Konody and Dr. Osten

Plurals of Nouns

XXXVII. The PLURAL OF PROPER NOUNS is formed in German as rarely as in English. Proper nouns shared by several persons, and those employed in a collective sense, remain sometimes unaltered in the plural—for instance: die beiden Frankfurt (*pl.*), the two towns of Frankfort; or add an -e, -en, -n, -r, -s: Ludwig (*s.*), Louis; and die beiden Ludwige (*pl.*) von Frankreich, the two Louis of France; but also die Ludwig (*pl.*) and die Ludwigs (*pl.*); die ſieben Eduarde von England, the seven Edwards of England (also die Eduard and die Eduards); Maria or Marie (*s.*), Mary; and die Marien von Schottland, the Marys of Scotland, etc. Proper nouns of Latin and Greek derivation either remain unaltered, or form the plural like other substantives of foreign origin.

XXXVIII. The DOUBLE PLURAL. Several substantives with the same or double gender, and with the same or different meaning, form the plural in two different ways:

Singular	*Plural*	*Plural*
der Akt, document, act of a drama	die Akten, documents	die Akte, acts
der Band, volume, and das Band, ribbon	die Bände, volumes	die Bänder, ribbons
die Bank, bench, die Bank, bank	die Bänke, benches	die Banken, banks
der Bauer, peasant, das Bauer, birdcage	die Bauern, peasants	die Bauer, birdcages
der Bund, union, alliance das Bund, bunch	die Bünde, unions	die Bunde bunches
das Geſicht, face, vision	die Geſichte, visions	die Geſichter, faces
der Laden, shop, shutter	die Läden, shops	die Laden, shutters
der Schild, shield, das Schild, signboard	die Schilde, shields	die Schilder, signboards
der Strauß, bunch of flowers, ostrich	die Sträuße, bunches of flowers	die Strauße ostriches

1. Several other nouns form a double plural without, and some with, different meaning —*e.g.*: das Gaſtmal (*s.*) banquet, feast, die Gaſtmale (*pl.*) and die Gaſtmäler (*pl.*); das Band (*s.*) tie, ribbon, die Bande (*pl.*) [der Natur, des Blutes, des Geſetzes], the ties [of nature, of blood, of law], and die Bänder (*pl.*) ribbons; der Ort (*s.*) place, locality, die Orte (*pl.*) places, and die Örter, communities; das Wort (*s.*) word, die Worte (*pl.*) words, and die Wörter (*pl.*) words in the sense of vocables; das Land (*s.*) country, die Lande (*pl.*) [rhetorical form] and die Länder (*pl.*) countries.

Interrogative Pronouns

XXXIX. The INTERROGATIVE PRONOUNS are: (*a*) wer? who? (*b*) was? what? (c) welcher (*m.*), welche (*f.*), welches (*n.*)? which? and (*d*) was für ein (*m.* and *n.*), eine (*f.*)? what sort of? Wer and was are used substantively; the former applied to persons, the latter to objects. The declension of (*a*), (*b*), (c) is:

	(*a*)	(*b*)	(*c*)	*Plural for all 3 genders*
nom.	wer	was	welcher welche welches	welche
gen.	weſſen (wes *)	weſſen (wes)	welches (en) welcher welches (en)	welcher
dat.	wem	—	welchem welcher welchem	welchen
acc.	wen	was	welchen welche welches	welche

---

* Used in proverbs, etc.: Wes das Herz voll iſt, geht der Mund über, Of what the heart is full, the mouth overflows.

Examples: (*a*) Wer fragt? Who is asking? (*b*) Was ſagſt du? What do you say?

1. Welcher, welche, welches is always either directly connected with, or used with reference to, a substantive; it has the character of an attributive adjective and is declined like one [see XXVI.] When used as an exclamation, it takes the shortened and indeclinable form welch, similar to the demonstrative pronoun ſolcher, ſolch, and mancher (many a), manch ein. In this case it is either followed by the substantive with or without an adjective, or by the indefinite article—for instance: welch ſchöner Tag, what [a] beautiful day; welch ſchöne Landſchaft, what [a] beautiful landscape; or, with inserted indefinite article: welch ein ſchöner Tag, welch eine ſchöne Landſchaft.

2. The indefinite article can *never* precede the interrogative pronoun welcher, whilst it may precede the demonstrative ſolcher: ein ſolcher Tag! such a day, but welch' ein Tag! what a day, and *never* „ein welcher Tag!“

3. Was für? What sort of? which? cannot be declined, and is used in direct connection with substantives denoting materials and abstract ideas—for instance: Was für Wein? What sort of wine? was für Glaube? which creed? In all other cases the indefinite article is inserted: was für ein Hut iſt das? what sort of hat is that? The indefinite article is of course declinable. Without substantive was für ein? takes the lengthened form was für einer (*m.*)? was für eine (*f.*)? was für eines (*n.*)? and is used substantively. Ein having no plural, the plural of was für ein is expressed by was für welche?

4. If the interrogative pronoun was? (what?) is used with the prepositions an, auf, über, nach, zu, etc. [see XXV.], it is replaced by the adverb wo, contracted with the prepositions (woran? worauf? worüber? wonach? wozu? etc.), the latter being placed at the end. For the sake of euphony an r is inserted between two vowels. It is not usual to say: An was denken Sie? What are you thinking of? but: Woran denken Sie? nor: Zu was dient dieſes Rad? What purpose does this wheel serve? but: Wozu dient dieſes Rad?

Prepositions

XL. The following is a complete list of the German prepositions arranged according to the cases ruled by them:

PREPOSITIONS GOVERNING THE GENITIVE:

anſtatt' (or ſtatt), instead of
au'ßerhalb, outside of, (without)
dies'ſeits, this side of
halber (or halben *), on behalf of
jen'ſeits, that side of
in'nerhalb, within
kraft, by power of
längs †, along
laut, according to
um . . . willen, for the sake of
un'beſchadet, without prejudice to
un'geachtet, despite, although
un'terhalb, beneath, below
un'weit (or unfern †), not far from
vermö'ge, in virtue of, by means of
vermit'telſt (or mittels), by means of
o'berhalb, above
trotz ‡, in spite of
wäh'rend, whilst, during
wegen *, on account of
zufolge †, according to, in consequence of

PREPOSITIONS GOVERNING THE DATIVE:

aus, out of, from
außer, except
bei, near, about, with
binnen, within
entgegen, against
gegenü'ber, opposite
gemäß', according to
mit, with
nach, after
nächſt (zunächſt'), next to
nebſt, with, together with
ob §, on account of
ſammt, together, with
ſeit, since
von, from, of, by
zu, to
zuwi'der, contrary to

PREPOSITIONS GOVERNING THE ACCUSATIVE:

bis, till
durch, through
entlang ¶, along
für, for
gegen, against, towards
oh'ne, without
um, for, about, around, on account of
wider, against, contrary to

For the prepositions governing alternately the dative and the accusative, and for the contractions of prepositions with the definite article, see XXV.

Classification of Verbs

XLI. The classification of verbs is most important, as it is the basis for the rules concerning the employment of the auxiliary verbs ſein and haben.

As regards their dependence and influence on other nouns, the verbs can be classified as follows: (*a*) ***intransitive***, (*b*) ***transitive***, (*c*) ***reflective*** and ***reciprocal*** [see 5], and (*d*) ***impersonal*** verbs [see 6].

(*a*) Intransitive verbs want no completion to convey their full meaning—for instance: die Sonne ſcheint, the sun shines; der Wind bläſt, the wind blows, etc.

(*b*) Transitive verbs require the aid of objects in the accusative to make their meaning fully obvious—for instance: das Kind liebt ſeine Eltern, the child loves its parents, etc. Transitive verbs can always be brought into the passive form if the ***object*** (accusative) is made the ***subject*** (nominative)—for instance: die Eltern werden von ihrem Kinde geliebt, the parents are loved by their child.

1. There are some verbs which require completion by a noun in the genitive or dative—*e.g.*: bedür'fen, to require, want; raten, to advise, etc.; ich bedarf deiner, I want [of] thee; and rate mir, advise me. These are not counted among the

---

* Is *always preceded* by the substantive: des lieben Friedens halber, for the sake of [dear] peace.

† Also used with the dative.

* Can be alternately preceded or followed by the substantive: Wegen des lieben Friedens, or des lieben Friedens wegen, for the sake of [dear] peace.

† Also used with the dative, if *preceded* by the substantive—for instance: Einem Berichte zufolge (*dat.*), according to a report; but: Zufolge eines Berichtes (*gen.*).

‡ Also used with the dative.

§ In poetic speech also with the genitive: Ob dieſer Kunde (*gen.*) herrſchte Trauer rings im Land, On account of this news mourning reigned throughout the land.

¶ Sometimes used with the dative, and very rarely with the genitive.

transitive verbs, the characteristic of which is the power to govern a noun in the accusative, but among the intransitive verbs.

2. Other verbs are used with prepositions and are thus connected with complementary nouns in the cases required by the prepositions—*e.g.*: wir lachten über ihn (*acc.*), we laughed at him; er ſtrebte nach Reichtum (*dat.*), he strove for wealth, etc. Bear in mind the essential difference between the *prepositional-accusative* of the intransitive and the *object-accusative* of the transitive verbs.

3. The same difference occurs in the case of the accusative determining the *measure* and answering to the questions: how much? how far? how long? etc., which always determine the *intransitive* character of the verb—for instance: der Kauf'mann wog den Zucker, the merchant (grocer) weighed the sugar (transitive); but: der Zucker wog zehn Pfund, the sugar weighed ten pounds (intransitive with accusative of measure).

4. Intransitive verbs can also be brought into the passive form by the introduction of the impersonal es, it: die Sonne ſcheint, the sun is shining; and: es wird von der Sonne geſchienen, which, though correct, is a clumsy form and should not be used.

5. Some verbs are only used in connection with certain personal pronouns, in the sense that the action is reflected upon the acting person. The complement (object) is here identical with the subject—for instance: Ich ſehne mich nach etwas, I long for something; er ſchämt ſich, he is ashamed, etc. These are called *reflective verbs.* If the acting persons are in the plural, a reciprocity of reflection may take place, in which case the verbs are called *reciprocal*: ſie ärgerten einander, they annoyed one another (each other).

6. *Impersonal* verbs denote either natural phenomena ascribed to impersonal agency, and are therefore used with the impersonal es, it; (examples: es regnet, it is raining; es donnert, it is thundering, etc.); or the impersonal action of certain feelings or sensations on persons: es hungert mich, I am hungry [it hungers me], etc. Verbs are also used impersonally to denote occurrences due to some impersonal motive power; es giebt ein Wie'derſehen, in the sense of there is the possibility of seeing each other again.

7. Many verbs belong alternately to both groups—the transitive and the intransitive—according to their relation to the object of the sentence.

EXAMINATION PAPER XI.

1. Which are the plural inflections of proper nouns?
2. What rule determines the use of the interrogative pronouns wer? and was?
3. What are the relative positions of the indefinite article and the shortened form of welcher [welch']?
4. By which compounds is the interrogative pronoun was replaced if it is used with the prepositions auf, über, nach, zu; and what has to be kept in mind with regard to euphony?
5. Which preposition governs different cases according to its position before or after the substantive?
6. What is the chief guide in determining whether a verb is transitive or intransitive?
7. To which class belong those verbs that require, for the completion of their meaning, a noun in the genitive or dative?
8. What is the characteristic case of the substantive governed by a transitive verb?
9. What is the difference between the accusative of measure and the object-accusative with regard to the verb?
10. How can sentences with intransitive verbs be changed into the passive form?
11. Have the impersonal verbs a larger scope in German than in English; and to what feelings, sensations, or ideas is the supposed impersonal action extended?

EXERCISE 1 [see last lesson]. Change the present tense in the following sentences into the imperfect and pluperfect. (Mind the arrangement of the sentence with regard to the past participle and finite verb.)

Ich nehme das Geld; der Knabe ſtiehlt einen Apfel;
I take the money; the boy steals an apple;
was geſchieht? ich leſe ein Buch; ihr ſeht
what happens? I am reading a book; you see
nichts; geben Sie nichts?* du verbirgſt
nothing; do you give nothing? thou hidest
etwas; wir werfen den Ball; die Dame ſpricht
something; we throw the ball; the lady speaks
engliſch; ich eſſe Erd'beeren;
English; I eat strawberries;
er vergißt alles.
he forgets everything.

EXERCISE 2. Insert the correct plural terminations of the following words with double plural form:

Das Luſtſpiel hat vier Akt . . .; in ſeinen Träumen
The comedy has four acts; in his dreams
hatte er ſeltſame Geſicht . . .; die Ritter erheben ihre
he had queer visions; the knights raised their
Schilde . . .; der Richter brachte die Akt . . . . Alle
shields; the judge brought the documents; all
hatten bleiche Geſicht . . .; die Schild . . . über den Laden-
had pale faces; the sign-boards above the shop-
türen waren gemalt; wie viele . . . . haben Sie?
doors were painted; how many volumes have you?
Die . . . . . . des Hutes ſind rot; die . . . . der Vögel
The ribbons of the hat are red; the birdcages
waren aus Gold; die . . . . kennen das Wetter.
were of gold; the peasants know the weather.

EXERCISE 3. Insert in the blank spaces the missing interrogative pronouns:

. . . . . iſt dieſer Herr? . . . . meinen Sie?
Who is this gentleman? What do you mean?
. . . . . . Hut iſt das? . . . . . . gehört dieſes Buch?
Whose hat is this? To whom belongs this book?
. . . . ſahen Sie geſtern? . . . . Manne
Whom did you see yesterday? To which man

---

* Be careful about the arrangement of the words.

gehört das Boot? ..... Dame kennen Sie?
belongs the boat? Which lady do you know?
.... Kinder ſollen eingeladen werden? ..... glänzender
Which children are to be invited? What [a] brilliant
Spieler er iſt! ...... ſchöne Kind ſahen Sie?
player he is! Which beautiful child did you see?
.... ſchönes Kind! .... Leute
What [a] beautiful child! What sort of people
ſind ſie? .... Getränke beſtellten Sie?
are they? What drinks did you order?
.... Frau war es?
What sort of woman was it?

EXERCISE 4. Insert the missing words and terminations in the cases required by the prepositions:

Diesſeits ... Mauer (*f.*), innerhalb ... Garten .. (*m.*),
On this side of the wall, within the garden,
ſtand ein Mann inmitten .... Wieſe (*f.*).
stood a man in the midst of the meadow.
Zufolge ein .. Bericht .. (*m.*) war der Feind geflohen,
and: Ein .. Bericht .. zufolge war der Feind geflohen.
According to a report, the enemy had fled.
Trotz mein .. Warnung .. (*f.*) ſprach er mit ihm;
In spite of my warnings, he spoke with him;
um ... Himmel .. (*m.*) willen! Mein .. Hauſ .. gegenüber
for heaven's sake! Opposite to my house
wohnt ein Schneider ſeit ein .. Jahr .. (*m.*); ich öffnete
lives a tailor since a year; I opened
(a tailor has been living for a year)
mittelſt .... Schlüſſel .. (*m.*) die Türe. Seit
the door with (by means of) a key. Since
Ihr .. Abreiſe (*f.*) ſah ich ihn nicht mehr;
your departure I did not see him any more;
wir ſpazierten durch ... Garten (*m.*) gegen ... Wald (*m.*);
we walked through the garden towards the forest;
er tat es wider mein .. Willen (*m.*).
he did it against my will.

KEYS TO EXERCISES IN EXAMINATION PAPER X. [page 2352].

EXERCISE 1. *Imperfect:* Ich band einen Kranz; der Vogel ſang; das Reh ſprang und trank; das Werk gelang; wir tranken Wein; das Waſſer rann ins Thal; er ſchwamm ausgezeichnet; ich ſaß im Garten; das Schiff ſank; die Glocke klang laut; der arme Mann bat, etc.; ich gewann das Spiel; er beſaß ein Haus.

Perfect: Ich habe einen Kranz gebunden; der Vogel hat geſungen; das Reh iſt geſprungen und hat getrunken; das Werk iſt gelungen; wir haben Wein getrunken; das Waſſer iſt ins Tal geronnen; er iſt ausgezeichnet geſchwommen; ich bin im Garten geſeſſen; das Schiff iſt geſunken; die Glocke hat laut geklungen; der arme Mann hat um eine Unterſtützung gebeten; ich habe das Spiel gewonnen; er hat ein Haus beſeſſen.

EXERCISE 2. Ein ſolcher Freund iſt ſelten; ſolch ein Freund iſt ſelten; er iſt der Sohn dieſes Mannes und jener Frau; wir ſprachen mit dieſem Knaben und mit jenen Männern; ſie ſprach viel von ihrer Tochter und von deren Erfahrungen; der Himmel iſt jenen gnädig, die ihn anrufen; der Jäger marſchierte hinter ſeinem Herrn und trug deſſen Gewehr; ich vertraue demjenigen, welcher mir vertraut; iſt dies Ihre Frau? Nein, dieſes iſt meine Couſine; dies ſind ihre Schweſtern und deren Gatten; ſie antwortete, ſie würde denjenigen Mann heiraten, der ihr am beſten gefiele.

EXERCISE 3. (*a*) Es iſt eine Freude, einen ſolchen Sohn zu haben. Ein ſolches Unglück! Eines ſolchen Mannes Sohn ſollte von anderer Art ſein. Wie konnten Sie einer ſolchen Frau eine ſolche Unhöflichkeit ſagen? Ein ſolcher Tag iſt ſchrecklich. Einem ſolchen Künſtler muß man einen ſolchen Irrtum verzeihen. Einem ſolchen Manne, einer ſolchen Frau, einem ſolchen Kinde bin ich noch niemals vorher begegnet.

(*b*) Solch ein Skandal wegen ſolch einer Kleinigkeit! Solch eines Mannes Pflicht iſt Großmut; ſolch einem Unglück gegenüber iſt der Menſch wehrlos; ſolch einen Fall habe ich in ſolch einer Familie noch nicht erlebt!

FEEDING & MOVEMENT OF BIRDS

continued from page 2314

Carnivorous and Vegetarian Birds. Hoppers, Walkers, Runners, and Climbers. Organs of Flight. Swimming and Diving Birds

By Professor J. R. AINSWORTH DAVIS

FOOD OF BIRDS

Birds of Prey. Eagles, falcons, hawks, harriers, buzzards [285], and the like are adapted for the pursuit of prey not only by possession of strong hooked beaks, powerful talons, and keen powers of vision, but also by the swiftness of their flight. Many of them—for example, falcons—are able to poise themselves, apparently motionless, in the air till some such prey as a young rabbit or small bird is discovered, and then swoop down upon the victim with almost incredible rapidity.

Carrion Eaters. The carrion feeding vultures are able to detect dead animals from very considerable distances by means of their keen sight, and are extremely gluttonous. The little Egyptian vulture (*Neophron percnopterus*) of North Africa, India, and part of Europe, is said to devote its attention to the bones of carcases which have been picked clean by other carrion eaters. In Spain it is known as the "quebrantahuesos" (bone smasher), because it breaks bones by carrying them to a height in the air and letting them fall on rocks.

A similar habit is attributed to the bearded vulture, or lammergeier (*Gypaetus barbatus*), and possibly tortoises may be cracked in the same rough-and-ready manner. Pliny asserts that the Greek poet Æschylus was accidentally killed by some such bird, which mistook his bald head for a convenient boulder on which to drop its prey.

The Snake's Foe. The curious African secretary bird (*Serpentarius secretarius*) is a long-legged form which pursues all sorts of small animals on the ground, and is particularly partial to snakes. The reptile is assailed with simultaneous blows from legs and wings, the latter also serving as a shield. In South Africa the bird is often tamed, rendering valuable service by the war it wages upon poisonous serpents.

287. MARTINS CHASING INSECTS

Owls [280] avoid competition with the ordinary birds of prey by feeding at dusk and dark, such small creatures as rats and mice bulking largely in their diet.

Insect-eaters. The tribe of insects supplies many birds with food. Swifts, swallows and martins [287] hawk for them on the wing during the day, and the night-jars in the gloaming. Tits, creepers, nut-hatches [286], and the like pursue them on trees, where also they are exposed to attacks from the powerful beaks of woodpeckers. Caterpillars are eagerly sought out by many small birds, and those which are too well protected by bristles to suit ordinary digestions are acceptable to the cuckoo. The grubs and pupæ of insects which live in the soil are probed for by many strong-billed birds, and insects in all stages inhabiting fresh water are by no means free from the ravages of wagtails and many other feathered enemies.

Fish Feeders. Fishes, again, are a very favourite kind of food with numerous birds. Sea-eagles and ospreys live mostly upon them, and the same is true of large numbers of aquatic forms. In average cases the beak of a fish-eater is elongated and tapering, often with a bent or hooked tip, as seen in the black cormorant [283], which fishes along the coast. Gulls and their allies go further from the land, and the albatross affects the open ocean. Nor are fresh-water fishes free from foes. Long-legged waders, such as herons, angle for them in the shallows, and kingfishers pounce down upon them from branches overhanging streams.

Some birds—for example, the divers—are able to pursue their finny prey a greater or less distance under water, and this habit is carried to an extreme in the penguins, the wings of which have been converted into efficient paddles [281].

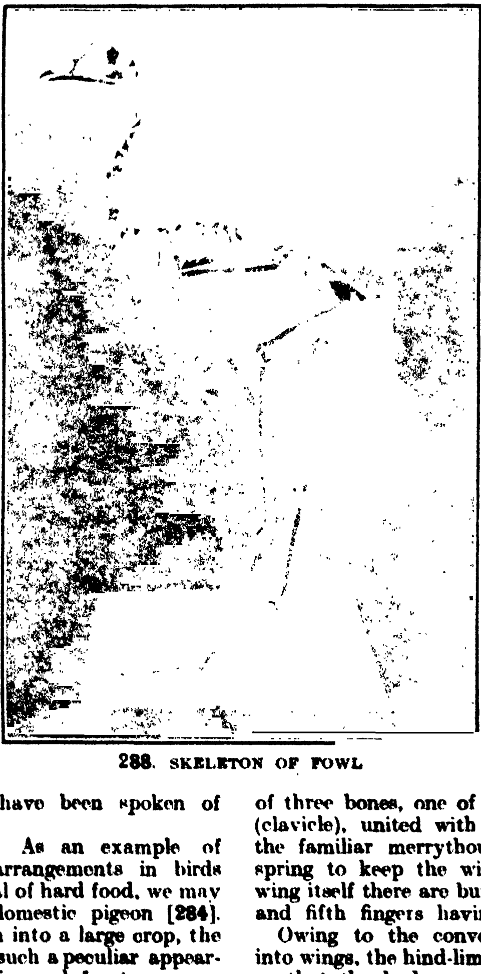
Worm-eaters. Worms of all sorts figure in the dietary of a host of birds, some of which possess long beaks adapted to probe for them in the earth, as well seen in the woodcock. The same is true of the kiwi of New Zealand, and here the nostrils are at the end of the long beak, instead of at its base, this being apparently an arrangement for smelling out the wriggling prey [277, page 2213].

Shell-fish of various kinds are also used as food by a number of birds. Gulls ravage cockle-beds, and the oyster-catcher, or sea-pie (*Hæmatopus ostralegus*), hunts for molluscs (and crustaceans) on the shore. The snails and slugs of the land and the snails of fresh water receive many attentions at the beaks of their enemies, and the thrush has learnt the art of cracking the hard shells of snails on some suitable stone, to which it returns again and again with fresh victims.

The broad bills of ducks and swans, which are adapted for feeding upon small worms, snails, etc., contained in mud, have extremely sensitive edges, and also a number of transverse ridges that serve as a sort of strainer. In geese these ridges are of use for cutting through herbage, while the mergansers find them helpful in securing fish.

In birds which affect a mixed diet, or feed on soft vegetable food, the beak is commonly a moderately long cone. Seed eating birds, such as finches, possess short strong conical beaks.

Vegetarian forms with beaks of peculiar shapes or character, such as crossbills, parrots, and toucans have been spoken of elsewhere.



288. SKELETON OF FOWL

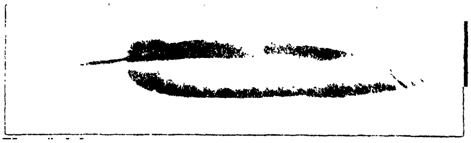
Digestive Organs. As an example of the internal digestive arrangements in birds which swallow a good deal of hard food, we may conveniently take the domestic pigeon [284]. Here the gullet is swollen into a large crop, the inflation of which gives such a peculiar appearance to a pouter. It is used for temporary storage and passes into a somewhat oval chemical stomach, from the lining of which the gastric juice is poured out. Then follows a rounded gizzard or mechanical stomach, with extremely thick muscular walls and a tough lining. This organ makes up for the absence of teeth, for it rhythmically contracts and dilates, thus bringing pressure to bear upon the food contained within it. Small stones and other hard objects are constantly being swallowed, which pass into the gizzard, there to play the part of millstones.

MOVEMENT OF BIRDS

Hopping, Walking, and Running Birds. Adaptation to flight has profoundly affected the structure of birds in a large number of ways, some of which may be gathered from the appended illustrations of the skeleton of a fowl [288] and of an osprey [290], the latter disarticulated and displayed. Of course, most of these peculiarities are still possessed by birds, such as ostriches, which have lost the power of flight. The somewhat boatshaped body is supported by a strong, bony framework, which allows of but little movement from side to side, largely because the joints of the backbone are here, for the most part, closely fused together. The inconvenience of this arrangement is compensated for by the fact that the neck is long and very flexible, as must have been observed by anyone who has taken the trouble to watch a living bird. Some of the joints of the short tail are free, but those at the end have fused into a ploughshare bone for the support of the quill feathers of that region.

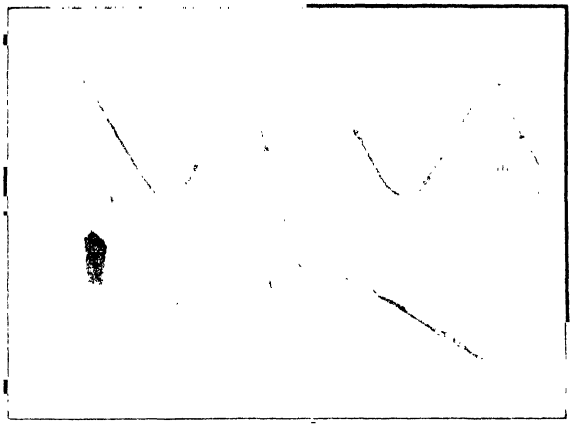
The Limbs. The breastbone (sternum) possesses a large projecting keel to which the muscles of flight are attached. The shoulder-girdle, to which the wing is jointed on, consists of three bones, one of which is the collar-bone (clavicle), united with its fellow to make up the familiar merrythought, which serves as a spring to keep the wings well apart. In the wing itself there are but three digits, the fourth and fifth fingers having disappeared.

Owing to the conversion of the fore-limbs into wings, the hind-limbs are set on far forward, so that the body may balance properly upon them. And, for their support, there are very long hipbones united to a region of the backbone (sacrum) composed of a number of its joints fused together. In order to further rapid progression when on the ground, the legs are fairly long, and this has been brought about much in the same way as in ruminant mammals. Beginning at the upper end, there is a rather short thighbone (humerus), followed by a long shinbone, an elongated shankbone — comparable to the cannon-bone of a ruminant—and four toes. The little toe has been lost. It will be seen that the bird walks on its toes—*i.e.*, is *digitigrade*, just like a hoofed animal.



289. QUILL FEATHER
Photographed by Prof. B. H. Bentley

The ankle is therefore raised off the ground, and corresponds in position to the junction between shinbone and shankbone. No little irregular ankle-bones are to be seen here, however, for in the interest of firmness half of them have united with the lower end of the shinbone, and half with the upper end of the shankbone. The instep-bones of the second, third, and fourth toes are fused to make up most of the latter.



290. SKELETON OF OSPREY
a Skull *b.* Lower jaw *c.* Radius *d.* Shoulder bones *e* Humerus *f.* Wrist *g.* Ulna *h.* Ribs *i.* Thighbone *j.* Shin *k.* Shank *l.* Hip-bone *m.* Sacrum *n.* Merrythought *o.* Breastbone *p.* Ploughshare-bone i, ii, iii, and iv. Thumb and fingers

Methods of Progression. Most small birds hop, some — *e.g.*, jackdaw — both hop and walk, while others, such as game birds, waders, and rooks, walk. In the flightless running birds, some of which vie with the fleetest mammals in speed, not only are the legs of great length, but we find instances of reduction in the number of toes already remarked among such forms as ruminants. The American ostrich has only three toes, and the African ostrich but two [292], of which the inner one (third) is much larger than the other (fourth). Note also the absence of a keel to the breast-bone.

291. WING OF BIRD
a. Radius *b.* Ulna *c.* Humerus *d.* Bastard wing *e.* Primary quills *f.* Secondary quills i, ii. Thumb and first finger

Climbing Birds. In many cases the foot of a perching bird is a grasping organ of sufficient power to be used in climbing without any structural modification. The sharp claws naturally play an important part here. Tits and nut-hatches [286] run up and down the trunks and branches of trees with equal facility. The writer has seen a nut-hatch alight on the surface of a plastered wall, holding on to the slightest irregularities, and maintaining itself in the same position—head downwards—for some time, without any apparent effort. Some of the sparrows, which regularly came to the same window as this particular bird and his mate to receive hospitality, had learned the same trick. When climbing upwards, the short strong tail of the nut-hatch can be used as a prop, and the same is true in a greater degree of the tree-creeper (*Certhia familiaris*), which, when searching for food, regularly begins at the bottom of a wall or tree and gradually works its way up.

In woodpeckers and parrots [282] the fourth as well as the first toe is turned backwards, thus constituting a specialised climbing foot. Some of the woodpeckers have gone further, and have become three-toed by loss of the first digit, while the fourth has become correspondingly efficient. The hooked beak of a parrot is as useful in climbing as in feeding.

Flight of Birds. Some of the special points in the structure of birds having relation to flight have already been mentioned, but there are still others which demand consideration. The specific gravity of the body is less than in mammals, partly owing to the lightness and spongy nature of the bones, many of which contain air-spaces. There are also a number of membranous air-sacs in connection with the lungs, by which the same end is furthered. But, in spite of all this, flying involves the expenditure of a vast

EARLY FORMS OF BRIDGES

Natural Bridges. Trussed Bridges. Brick and Stone Arched Bridges. Suspension Bridges. Iron Girder Bridges

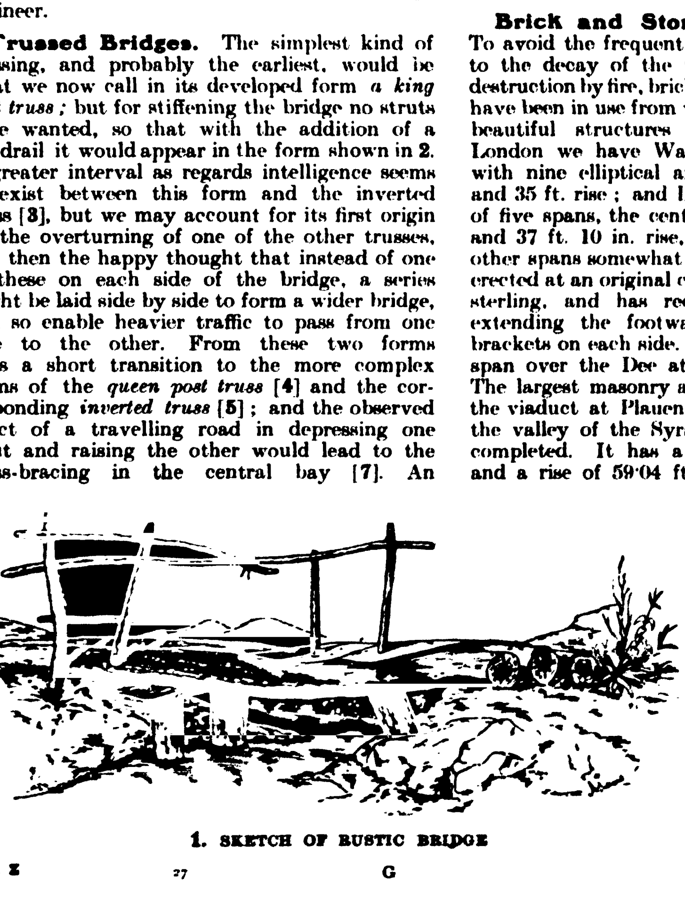
Continued from page [illegible]

By Professor HENRY ADAMS

Natural Bridges. The earliest bridge was, without doubt, formed by the accidental falling of a tree across a stream, probably by the scour carrying away the earth and undermining the roots, so that the tree overbalanced and fell on that side. Following the example set by Nature, it is an easy step to form a good bridge for a short span by placing two or more tree trunks side by side across a stream, and we may readily suppose that the branches were lopped off and used in short lengths laid across the trunks to form a very passable footway. A rustic bridge not far removed in principle from that described is shown in **1**. We may grant this much as due to instinct or imitation ; it was not engineering. When, however, a wider span had to be crossed, so that some form of trussing was required, the necessity for invention arose, and with it the first bridge engineer.

Trussed Bridges. The simplest kind of trussing, and probably the earliest, would be what we now call in its developed form *a king post truss ;* but for stiffening the bridge no struts were wanted, so that with the addition of a handrail it would appear in the form shown in **2**. A greater interval as regards intelligence seems to exist between this form and the inverted truss [**3**], but we may account for its first origin by the overturning of one of the other trusses, and then the happy thought that instead of one of these on each side of the bridge, a series might be laid side by side to form a wider bridge, and so enable heavier traffic to pass from one side to the other. From these two forms it is a short transition to the more complex forms of the *queen post truss* [**4**] and the corresponding *inverted truss* [**5**] ; and the observed effect of a travelling road in depressing one strut and raising the other would lead to the cross-bracing in the central bay [**7**]. An early type of timber bridge was one built in Glasgow, in 1832, in 34 ft. spans, as shown in **7**. It is very simple in construction, and upon the same principle as the ordinary stone-yard gantry. Many timber bridges of this character exist across canals in various parts of the country, and there are also some across the upper reaches of the Thames. We need not trace the gradual improvements that were made even if it were possible ; it will suffice to notice the modern form of timber bridges for large spans, used principally for pioneer work in America, and shown in **8** and **9**. In some of the larger spans wrought-iron rods or long bolts are used for the tension members ; they overcome in a very simple manner the difficulty of framing timber to withstand tensile stress. Some of these bridges are covered by wooden roofs.

Brick and Stone Arched Bridges. To avoid the frequent renewal of bridges owing to the decay of the timber, or the accidental destruction by fire, brick and stone arched bridges have been in use from very early times, and some beautiful structures have been erected. In London we have Waterloo Bridge, of granite, with nine elliptical arches, all of 120 ft. span and 35 ft. rise ; and London Bridge of granite, of five spans, the centre one 152 ft. 10 in. span and 37 ft. 10 in. rise, as shown in **10**, and the other spans somewhat smaller. This bridge was erected at an original cost of nearly half a million sterling, and has recently been widened by extending the footway over stone cantilever brackets on each side. A stone bridge of 200 ft. span over the Dee at Chester is shown in **11**. The largest masonry arch bridge in the world is the viaduct at Plauen, in Saxony, which bridges the valley of the Syra, and was only recently completed. It has a clear span of 295·4 ft., and a rise of 59·04 ft., and carries a roadway 36·8 ft. wide with two pathways each of 9·84 ft. width. The arch forms a composite curve, being struck from five centres, the crown having a radius of 344·4 ft., the springings 192 ft., and the haunches 98·7 ft. radius. It was designed for loads which include a train of 15-ton waggons, or of three steam rollers, weighing 23 tons each. The arch ring is built of bluish-



1. SKETCH OF RUSTIC BRIDGE

grey stone from the Theuma and Tippersdorf quarries, laid in cement mortar. At the springings it is 13·12 ft. deep, and at the key 4·92 ft. deep. The work was started in August, 1903, and completed in the summer of 1905, the total cost being about £29,500, inclusive of about £1,000 spent in land purchase. The largest brick arch bridge is the Great Western Railway bridge over the Thames at Maidenhead, with an elliptical arch having a span of 128 ft., and rise of 24 ft 3 in.

Suspension Bridges. "Next to a common log or beam, the most simple and easy contrivance for establishing a constant communication from bank to bank of a river, or between projecting portions of an intervening gap, is that of a rope or flexible line ; indeed, the necessity must have given birth to the idea." (Warr.) In India and South America animal hide and vegetable fibre were the chief materials employed, but in Bhootan, north-east of Hindustan, there is a suspension bridge with iron chains of such antiquity that its origin is lost in fable.

Another ancient iron-chain suspension bridge exists in the Yun-nan province of China. In Europe they do not appear to have been used before the eighteenth century. The first in England was built over the Tees, near Middleton, in Yorkshire, about 1741. It was nearly 70 ft. long and only 2 ft. wide, consisting of a footway laid on chains stretched nearly straight. This is probably typical of the earliest forms, the later method being to suspend the footway by vertical bars of different lengths from the curved chains, so that it may be kept level throughout, and the chains being hung with a greater dip are under less tension. The reduction of stress is directly proportional to the increase of dip, except for the extra weight of metal due to the greater length round the curve.

A chain of uniform weight hanging freely takes the shape of a *catenary* curve, while if the weight be distributed uniformly over the horizontal width of span the curve will be that of a *parabola*. In practice the shape is usually that of a *modified catenary*. The great bridge at Freiburg, shown in **12**, was 807 ft. span and 65 ft. deflection. Each of the main suspension cables, 5¼ in. in diameter, was composed of 1,056 lines of wire 0·12 in. diameter, passed through a boiling mixture of linseed oil, litharge, and soot, to prevent corrosion. The Menai suspension bridge, 580 ft. span, with a deflection of 43 ft., consists of 16 chains in four groups of 4, dividing the bridge into three lines of way, the central 4 ft. wide for foot passengers, and the two outer each 12 ft. wide for general traffic. The 16 chains were composed of links or bars of wrought iron in sets of five, 10 ft. long, 3¼ in. broad, and 1 in. thick, with a hole 3 in. in diameter bored in each end for the connecting pins. The entire cross-section, therefore, consisted of 5 × 16 = 80 bars, with a total sectional area of 80 × 3¼ × 1 = 260 sq. in. The Hungerford suspension bridge, first erected over the Thames and now placed over the Severn at Clifton, is 702 ft. span with 50 ft. deflection. In its present position it has a very fine appearance, owing to the height of the banks upon which the towers are placed, and although the rise of the tide reaches to 36 ft., there is ample headway for ships to pass under without lowering their masts. The Saltash Bridge over the Tamar, near Plymouth, is a unique structure designed by I. K. Brunel. It consists of two spans, each formed of an elliptical iron tube, arched upwards and braced by wrought-iron rods to chains dipping similarly to those of a suspension bridge. It is, in fact, a suspension bridge with the pull of the chains resisted by the overhead arched tube instead of by anchor blocks buried in the ground on either side.

Iron Girder Bridges. The earliest iron bridges naturally took the form of simple beams, but the limit of strength for this form was soon reached. The experiments of Fairbairn and Hodgkinson showed that hollow beams could be built over much greater spans, and following up the principles they discovered, they constructed the Conway and Britannia tubular bridges, like a long rectangular tube with flat sides and cellular top and bottom, the Britannia bridge over the Menai Straits being shown diagrammatically in section by **13** and in pictorial elevation by **14**, where the greatest span is 460 ft. in the clear. Bridges of this type, although based upon sound principles, did not meet with much favour, owing to certain drawbacks involved. They are in effect iron tunnels, are difficult to protect from corrosion inside on account of the steam from the locomotive engines, and outside from the sea air. They also present a continuous surface of great area to the force of the wind, and the positions where bridges of such span are required are usually very exposed. The improvements introduced in the construction of modern bridges will be dealt with subsequently.

Cast-iron Bridges. About the same time Telford was constructing cast-iron bridges, of which Southwark Bridge over the Thames at London is the finest example. It is the largest cast-iron bridge, the middle arch having a span of 246 ft. with a rise of 23¼ ft. The two side arches are 210 ft. span and 18 ft. 10 in. rise. The arches themselves consist of eight ribs with webs 2½ in. thick and flanges 4¼ in. thick ; these are 6 ft. deep at the crown and 8 ft. at the springing, in 15 divisions attached by means of dovetailed sockets and wedges. The spandrils, or spaces between the arch and roadway, are filled up with cast-iron framing of diagonal struts, bearing cast-iron plates, upon which the roadway lies. Other bridges of the same type were built at Tewkesbury and elsewhere. One of the most pleasing was built at Craig Ellachie, over the Spey in Inverness-shire, with a span of 150 ft. and a rise of 20 ft. It may be noted that cast-iron bridges were based upon the principle of the arch, thus utilising the extraordinary compressive strength of the material.

Continued from page 2421

THE TRIAL BALANCE

Its Object. Methods of Preparation. Totals and Balances. Errors Disclosed and Undisclosed. Compensating Errors

By J. F. G. PRICE

THERE are in many cases factors other than goods and returns to be taken into account in order to arrive at a true statement of gross profit. For instance, there are the items of freight, duty, carriage, etc., which add very largely to the cost of purchases from abroad. We cannot exactly describe them as "goods," but neither are we at liberty to ignore the bearing which they have upon the question of gross profit.

Trading Account. Evidently, we must have an account more comprehensive in its title than the goods account, one that will embrace all items which directly affect gross profit on trading. At the same time, we require that this account shall be easy of interpretation and analysis, and to that end we must take care that it is simple and concise. Our requirements are met by the "trading account," which, unlike the goods account, is not opened until the end of a business period. Under this plan provision is made for the monthly totals of purchases, sales and returns, which have hitherto been posted to goods account, by raising separate accounts for purchases and sales in the private or in the general ledger. To the debit of purchases account are posted the monthly totals of the invoice book, and to the credit of the same account are posted the monthly totals of the returned outwards book, the difference between the two sides representing net purchases.

Closing the Account. The account is closed by means of a transfer entry passed through the journal and posted to the ledger, crediting purchases account and debiting trading account with the amount of such difference. To the credit of sales account are posted the monthly totals of the day book or sales journal, and to the debit of the same account are posted the totals of the returned inwards book for the period, the difference between the two sides representing net sales. The account is closed by means of a transfer entry passed through the journal and posted to the ledger, debiting sales account and crediting trading account with the amount of the difference. The item "stock in trade" or "stock on hand," instead of appearing in the goods account as heretofore, is now shown in a separate account headed "Stock," the amount on hand at the beginning of a period being on the debit side, in accordance with the rule for real accounts to "debit what comes in." At the end of the period, stock account is relieved of this old debit, being simultaneously burdened with a new debit for the value of the stock on hand as ascertained by stocktaking.

Here, again, recourse is had to transfer entries in the journal. So far as the old stock is concerned, trading account has had the benefit of it, and we therefore credit stock account and debit trading account with the value of the stock at the beginning of the trading period. But with regard to stock on hand at the end of the trading period, it is clear that this must form part of the goods purchased during that period, and perhaps there is, besides, some of the old stock still unsold. We must, therefore, relieve the trading account to the extent of the present value of the whole of the unsold goods reckoned at cost or under; and this we proceed to do by passing another transfer entry through the journal, debiting stock account and crediting trading account. So far, then, we have on the debit side of trading account two items:

(*a*) Stock on hand at beginning of period, (*b*) net purchases during the period; and on the credit side two items: (*a*) stock on hand at end of period, (*b*) net sales for the period.

Other Charges. But in many businesses—the wholesale confectionery business, for example,—freight, duty, etc., must be added to the cost of the purchases before we can arrive at a true balance of gross profit. Accordingly, an account headed "freight, duty, carriage, etc.," is opened in the general ledger, and to this account are posted all cheques and petty cash payments made throughout the trading period on account of imports and other purchases on trading account. If at the end of the period there are any outstanding accounts for freight, warehouse and rail charges, cartage, etc., they must be journalised by debiting the carriage, etc., account and crediting a sundry creditors' account. By this means the whole of the expenditure proper to purchases for the period will be shown regardless of whether it has actually been met or is still due at the time of stocktaking. The account is closed by means of a transfer entry passed through the journal and posted to the ledger, debiting trading account and crediting freight, duty, and carriage account, with the debit balance shown on the latter.

Reproductive Wages. There are, moreover, a great many manufacturing concerns which purchase raw material and expend labour upon it, relying upon the sales of the finished product to return them a satisfactory gross profit. In such cases we should raise a separate account for reproductive, or manufacturing wages. Such wages are called *reproductive* because, although they represent an addition to the cost of the purchases, they also add to the value of the articles offered for sale, and may therefore be regarded as recoverable out of the sums realised for sales. The manufacturing wages account is thus a part of the trading account, and at the end of the business period will be closed by the transfer of the total net debit to the trading account itself.

Gross Profits. We have now considered the chief ingredients in the trading account. It is a moot point whether cash discounts on purchases ought to be included in the trading rather than in the profit and loss account, but we need not discuss the matter at present. Special notice is to be taken of the fact that the trading account, consisting as it does of an aggregation of the balances of various subsidiary accounts, serves to focus the whole of the business operations throughout a given period which affect the ultimate gross profit. If there is, as there certainly ought to be, a credit balance on trading account, this is the measure of the gross profit earned, and the trading account is closed by debiting the amount of the gross profit thereto and crediting it to the profit and loss account. Where a combined trading and profit and loss account is adopted, it is scarcely necessary to make a journal entry for transferring the gross profit from trading to profit and loss account; it is sufficient, if the upper (trading) portion of the combined account is balanced off by placing the gross profit balance on the debit side thereof and bringing it down on the credit side of the lower (profit and loss) portion of the combined account.

The Trial Balance. Before proceeding to deal further with the balance thus transferred to the profit and loss account, it will be well to retrace our steps a short distance for the purpose of considering in greater detail than we have yet done the table of debits and credits on page 490. That table, or trial balance, consists of a list of all the accounts in the ledger of X., as exhibited on pages 489 and 490, with the totals of the debit and credit entries made on each account shown in two columns. The trial balance proves the correctness of the statement that as every debit in the ledger has a corresponding credit for a similar amount, the total of all the debits must at any time equal the total of all the credits.

Upon reference to the table it will be seen that there are three accounts—A, B, and C—with the same amount entered on the debit as on the credit side. This being so, the agreement of the gross totals of debits and credits will not be affected if these accounts are altogether omitted, since both gross totals will be decreased by the same amount.

This principle may be taken a step further and applied to the cash account. The sum of the debits on that account is £1,145, whilst there is £20 on the credit side. If, therefore, £20 be deducted from both sides, the cash debits will become £1,125, and the credits nil. This operation, also, has no effect on the agreement of the gross totals, since each of them is reduced by the same amount—*viz.*, £20.

The observant student will perceive that the amount now included in the debit column of the trial balance under the head of cash is the balance of the cash account given on page 489, such balance being obtained by deducting the lesser side of the account from the greater.

Total and Balance Methods. The facts just considered point to two conclusions:

(1) That those accounts which have the same total amount on the debit as on the credit side may be omitted from the trial balance.

(2) That it is necessary to include in the trial balance only the balances, and not the totals of the remaining accounts.

To show quite clearly that we are justified in arriving at these conclusions, and that the omissions may safely be made without impairing the usefulness of the trial balance, the careful attention of the student is directed to the table on the following page, showing side by side the two methods.

This table should enable the student easily to understand why agreement is obtained between the totals of the debit and credit columns of a trial balance consisting of the balances of ledger accounts, since it shows clearly that the balance of an account is the amount remaining after deducting the same amount from each side. Thus, in the case of "Bank," the amount of the smaller side—the credit—is deducted, leaving £414 3s. 2d. in the debit column, and nothing in the credit column. In the case of "Sales," the smaller amount being in the debit column, the sum of £152 10s. 0d. is deducted, leaving nothing to debit, and £6,547 10s. 0d. to credit.

Closed Accounts Omitted. It is obvious, having regard to the amount of the purchases and sales, that all the accounts in Smith & Jones' ledgers have not been brought into the trial balance. Our personal accounts number only eight in all, while the transactions to which they relate amount to only some £1,700 to £1,800. The only reason for the omission of the rest of the personal accounts is consideration of space, and their non-inclusion does not affect the agreement of the gross totals, since their debits and their credits must be equal.

The plan of preparing the trial balance by showing the totals rather than the balances of the several accounts has only one real recommendation, and even that is not applicable to modern methods of bookkeeping. When every transaction was entered in detail in the journal and posted thence separately to the ledger, the trial balance on the total system provided an additional check on the accuracy of the work, in that the gross totals agreed with the totals of the debit and credit columns of the journal. As we have seen, however, modern requirements have forced the business community to adopt labour-saving devices in regard to accounts as in other matters. The existence of several journals would render the obtaining of such a check somewhat difficult, and the result would hardly justify the labour entailed.

The Balance Method. But there is another and more weighty reason for the adoption of the balance system. A trial balance made up of the balances of the open ledger accounts contains within itself all the materials necessary

TRIAL BALANCE EXTRACTED FROM THE LEDGER OF SMITH & JONES, ON 31ST DECEMBER, 1905

Name of Account.	Totals.		Balances.

for the preparation of the profit and loss account and the balance sheet, with the exception only of the amount of the stock on hand at the close of the trading period.

This reason alone would have been sufficient to bring about the adoption of the balance method, in preference to the total method; but when it is realised that there are in a business of moderate size many accounts where both sides agree in total—*i.e.*, where debits equal credits—it scarcely needs be stated that the balance method is used by accountants owing to the amount of labour saved by their being able to omit such accounts from the trial balance.

Object of Trial Balance. It is the desire of every trader to ascertain periodically (1) what are his profits or losses; and (2) what is his present position as regards assets and liabilities. To obtain the answer to these questions, he must prepare a profit and loss account and a balance sheet. But before he commences to do this he must first know that the work of recording his commercial transactions in his books has been correctly performed. The trial balance goes a very long way toward giving him this information, and it is, perhaps, no exaggeration to say that when a merchant or his accountant arrives at an agreement in his trial balance, he assumes the correctness of the work as a whole, and proceeds to the preparation of the profit and loss account and balance sheet. It should be mentioned, however, that there are certain errors which are not disclosed by a trial balance, and which may exist, although the gross totals of the latter agree. That is a matter which will engage our attention presently, but which need not detain us now.

The importance of the trial balance in relation to the final accounts—*viz.*, the trading and profit and loss account, and the balance sheet—cannot be over-estimated. Indeed, it needs very little consideration on the part of even a tyro to appreciate the necessity of proving the accuracy of the books before proceeding further. The manner in which the test of accuracy is applied is by the preparation of a trial balance. This, as already shown, consists of a list of all the open ledger accounts, arranged with debit and credit columns, in which are entered the balances. It must be clearly understood that the trial balance forms no part of the general scheme of accounts, and is not entered in the ledger or any other book. It is made up on loose sheets, and its object is to ascertain if the debit and credit sides of the ledger agree.

Errors Disclosed by Trial Balance. If the totals of the debit and credit columns of the trial balance do not agree, it is useless to proceed to construct the balance sheet until the cause of the difference has been ascertained. Before commencing a search in the ledger and other books, the bookkeeper will first make sure that the error is not in preparing the trial balance itself. The casting of the columns must be checked. If this does not result in discovery, the separate amounts must be compared with the accounts in the ledger to see that the balances have been correctly brought into the trial balance, both as regards amount and the column in which they have been entered. The casting of the ledger accounts must be checked to ensure that the balances struck are correct. Where an account has been omitted because both sides apparently agree, the castings must be carefully revised, to see if by chance there is really a balance on the account that should be included. If these steps do not result in the discovery of the difference, a search should be instituted for an item of the same amount as the difference, as it may be that it has been posted to only one side of the ledger; or the difference may be halved and a search made for the resulting amount, as it is possible that an item of that amount has been posted to the wrong side of the ledger. In such an event the effect on the balance of the account will be twice the amount so posted.

Other Measures. If none of the above suggestions result in the difference being found it will probably be best to call over the postings of the books of first entry into the ledgers. This, in the case of a large business, is a work of considerable magnitude, and is usually the last step to which recourse is had. In fact, the labour involved is so heavy that a system has been devised by which, where a large number of ledgers are in use, it is possible to locate an error as being in a particular book, and thus save an immense amount of time in the event of the trial balance of the whole of the ledgers not agreeing. This system is known as *sectional balancing* or *self-balancing ledgers*, and will be explained in detail later.

However small the amount of a difference may be, it *must* be traced, as there is always the danger that it represents the balance of two or more errors of large amount, and is not a simple error in itself.

Hints on Posting. One or two hints with regard to the mechanical work of posting, with a view to guarding against errors, will not be out of place here. Care should be taken in forming all figures; fives, eights, and threes should be quite distinct from one another, as should sevens and nines. The tails of the two last-named numbers should not be carried down too low, or they may be mistaken for ones in the line beneath. Do not enter figures too close to the binding. The writer has a lively recollection of a search extending over weeks for an item of fivepence, which was at length discovered almost out of sight in the bound edge of the book. Care must be taken in the pounds column to keep units under units, tens under tens, etc. In banks and other establishments dealing with large amounts, faintly ruled lines are provided in that column in order that the cashiers may strictly and yet easily conform to this rule. Post all debits first, and do not commence posting credits until the debits are exhausted. If it can be arranged, it is better for one clerk to post the debits and another the credits.

Compensating Errors. It was stated on page 2502 that there are certain errors which the trial balance does not disclose. These may be classed generally as compensating errors. They are so called for the reason that they have a twofold effect. They are the more difficult of detection for the very reason that the trial balance does not reveal them, and search cannot, therefore, be made for them at the time of balancing the books, as their existence is not known. They are brought to light by different means, according to their nature. This will be more clearly understood if we deal with specific instances:

(1) INCORRECT CASH-BOOK ENTRY.

An incorrect amount has been entered in the cash book as received from a customer.

This would not affect the balancing of the books, for the incorrect amount entered as received on the debit side of the cash account will also be entered on the credit side of the customer's account. The error will be discovered when counting the cash for the purpose of checking it with the balance of the cash account. If this operation be carried out daily, as dictated by ordinary prudence, the error would not have serious consequences, as it would probably be discovered before the amount had been actually posted to the customer's account.

(2) WRONG AMOUNT OF PURCHASE OR SALE.

Entry of an incorrect amount in the invoice book or purchases journal.

The amount will be posted to the ledger to the credit of the seller of the goods, and would also be included in the total of the purchases for the week or month, as the case might be, and posted to the debit of the goods or purchases account. This, it is clear, would have no effect on the balancing of the ledger, and would not, therefore, be discovered at balancing time. It would not, however, be discovered so quickly as the preceding instance, for, as we have seen, the balance of the goods account does not necessarily, or even probably, agree with the value of the goods in hand. And even if it did this fact would not lead to discovery at once; for stock, unlike cash, is not counted daily or even frequently, but at intervals sometimes of as long as twelve months. The error will probably remain undetected until the monthly statement of account is received from the seller and compared with the ledger account before being passed for payment. A similar error committed in the day book or sales journal would be discovered when rendering the monthly statement to the purchaser, who would promptly repudiate liability if he had been overcharged, and who should, of couse, call attention to the error if he has been undercharged

(3) POSTED OR ENTERED TO WRONG ACCOUNT.

(*a*) An amount posted to the right side of the wrong account.

(*b*) An amount entered to the wrong account.

Obviously, this will not affect the balancing of the books, as the amount appears on the proper side of the ledger. Suppose it be cash received from Y, but posted to the credit of X. The error will be discovered when sending in a statement of account to the former. He would point out that he had not been credited with the payment, and a reference to the cash book would show that the sum had been erroneously credited to X.

If the error arose in the posting of a sale of goods it would come to light in the same manner by charging the person with goods he had not received. Upon hearing from him that he had not

(4) PURCHASE TREATED AS SALE.

This would be posted to the debit of the customer, then included in the total of sales for the month, and posted to the credit of sales or goods account. The double entry principle having been observed, the balancing of the ledger is not affected. It should not be necessary in such a case as this to wait either for repudiation by the supposed customer charged or for the statement from the person who sold the goods. An intelligent clerk would know from the name and address that, instead of being a buyer, the supposed customer is really a seller, and an inquiry would result in the discovery of the error. Further, in a business of any size, a separate ledger would be kept for the accounts of sellers and another (or several) for those of customers. The fact of a new account being necessary for a familiar name should lead to inquiry and the detection of the mistake.

Danger of Double Errors. Owing to the nature of compensating errors, their detection is not a matter depending upon the correct balancing of the books, but rather upon common-sense and the alertness of the clerks in charge. Careless checking of statements of account or failure on the part of a customer to notify an undercharge will result, in the absence of other means of discovery, in an error of this nature remaining undetected. Too much stress, therefore, cannot be laid upon the necessity of a bookkeeper looking upon himself not as a mere machine for recording whatever is put before him, however improbable, but of using his intelligence and making such inquiries as, from the nature of the transaction, appear desirable, in any case where a doubt is raised of the accuracy of the original entry.

In the next chapter the profit and loss and the balance sheet are dealt with. Meanwhile, students are invited to test their progress by working the following exercises, selected from a Grade II. Bookkeeping Paper set by the Society of Arts in 1904.

John Shaw, having opened an account with the Dales Bank, Ltd., by paying in £4,200 to his credit, on October 12, 1903, purchased (by cheque) on the following day, the Duchess Slate Quarry from William Black, the purchase price (after valuation) being —Freehold land and quarry, £2,350; stock of slates, £300; and machinery, plant, tools, etc. £350. The following were his transactions up to November

24. Drew cheque £73 7s. 9d. for wages, and paid the same.
Banked cash received for cartage, £4 2s. 6d.
27. Made G. Hill an allowance for 250 broken slates (invoiced on Oct. 19, 1903), and made a claim upon the railway company for the amount.
28. Received cheque from G. Hill in settlement of his account, less 5 per cent. discount allowed.
Bought 3 tons of rails at £5 a ton from Rotherham Forge Co., Ltd.
29. Sold Parker and Co. 1,500 slates at £7 4s. per 1,000.
31. Sold D. Green 4,200 slates at £8 3s. 4d. per 1,000.
Drew cheque and cashed same (for petty cash) for £11 15s. 4d., the petty cash being kept upon the "imprest" system.
Paid manager's salary for the month, £30.
Drew cheque £68 3s. 7d. for wages, and paid the same.
Nov. 5. Received cheque £10 from Parker and Co. (on account).
Bought oil and other stores from Slippery & Co. for £4 10s.
6. Paid Sharp & Co. cheque £21 for legal charges.
7. Parker & Co's cheque for £10 returned by the bankers dishonoured, the bank charges on same being 1s.
Drew cheque £70 8s. 4d. for wages, and paid the same.
Banked cash received for cartage, £7 14s.
Bought 10 cwt. blasting powder at £5 a ton from Dynamite & Co., Ltd.
10. Received cheque from Parker & Co. for £10 (on account).
16. Bought timber from D. Green for £16.
19. Received cheque from railway company for claim (in full) made Oct. 27, 1903.
21. Drew cheque for self for private purpose £20, and cashed same.
Drew cheque £62 17s. 6d. for wages, and paid the same.

Pass the above transactions through the proper books to the ledger; balance the accounts as on Nov. 21, 1903: bring down the balances and extract a trial balance. No profit and loss account or balance sheet to be raised.

NOTE. No particulars being given as to the petty cash cheque for £11 15s. 4d. this amount must be entered in one sum in the main cash book. Wages need not be passed through the petty cash book in this case.

COURTSHIPS & NESTS OF BIRDS

Meanings of Colours of Plumage and Eggs. Birds as Lovers. Architecture of Nests. Varied Materials. The Cuckoo

By Professor J. R. AINSWORTH DAVIS

CLOTHING OF BIRDS

Protection Against Cold. It is important that the body of an aquatic bird should be protected against chilling, which is all the more necessary since the temperature of the blood is higher than in any other animals. This is effected in two ways. There is a good deal of fat below the skin, which plays the same part as the blubber of seals and whales. And, besides this, there is an oil gland under the skin on the upper side of the tail. By means of the beak this is applied to the plumage, which, therefore, never really gets wet. It may also be added that the large amount of air entangled in the feathers prevents the escape of heat from the body, and this applies to birds in general, not merely to aquatic ones.

COLOURS OF BIRDS

The colours of birds can be referred to the same classes as those of mammals, which have already been described [page 2156], and some of them will be illustrated in the later part of this lesson.

Protective Colouration. Protective colouration is exemplified by many eggs which are exposed to view, by most young birds which run from the egg, and by a large number of adult birds of both sexes. The last is more particularly true concerning female birds, which are very often inconspicuous or even dowdy in appearance, their preservation being more important for the species than that of the more volatile males, which do not as a rule play so important a part in the rearing of the young.

313. TURKEYS "IN LOVE"
Photographed by Prof. B. H. Bentley

Aggressive Colouration. Aggressive colouration is seen in some of the birds of prey, which harmonise in appearance with their surroundings, and are therefore not so likely to be perceived by their intended victims. This, however, is not so important as in mammals, for such forms mostly rely upon sudden and rapid flight for securing their meals. Beautiful courtship colours are often to be noticed, generally in the male, as we shall presently see. Warning colouration, advertising powers of defence, are exemplified by some of the noisy and quarrelsome friar-birds of the East Indies, and these serve as models to certain inoffensive orioles, which unconsciously mimic them, and thereby are able to exist in comparative peace and quietness. Black and white recognition markings, as in the case of antelopes, are to be found in many of the plovers, and probably enable members of the same species to know one another at first sight. The jewel-like tints of humming birds perhaps have this significance.

COURTSHIP OF BIRDS

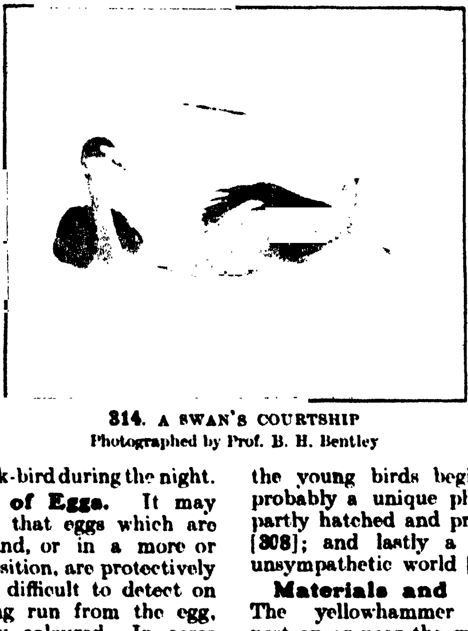
It is only natural that the tender passion, which quickens the sluggish pulses even of cold-blooded amphibians and fishes, should stir to its profoundest depths the restless bird-nature, which lives at an unusually rapid pace. The coy female is courted by devices of the most varied nature. It may be that the male is aided by colours of the most resplendent kind, of which extreme cases are afforded by the bravery of the cock-pheasant [**272**] and the wonderful tail-feathers of the peacock [**269**, facing page 2209]. Even the familiar inhabitants of the farmyard illustrate the same phenomenon, as may be seen in the turkey, of which the appended illustration [**313**] represents two "gobblers" with fully displayed plumage competing for the affections of a hen, the lady in this case appearing to favour the suit of the—to our tastes—uglier lover. Sometimes there is no great difference in the external appearance of the sexes, as in swans, our illustration of which [**314**] shows a male ardently swimming round his desired mate.

Dance and Song. There are a number of birds in which the brightly coloured or otherwise decorated males execute strange love antics and amatory dances, which are not without their effect on the opposite sex. In many forms comparatively dull plumage is fully compensated for by the possession of powers of song, and such love-ditties constitute for us one of the subtlest charms of returning spring. As among many mammals, the males are particularly combative during the spring, especially in species which are of polygamous habit. A good example is found in a bird of the plover kind, the ruff (*Machetes pugnax*), in which the cock-bird grows a beautiful feather-frill round his neck at the pairing time.

A Female Wooer. It sometimes happens that the rules of courtship are reversed, the hen, in this case the more brilliantly coloured, playing the active part, and paying her suit to the retiring male. A kind of plover, the dotterel ([illegible] *morinellus*), illustrates this highly indecorous—or, shall we say, "advanced"?—procedure.

NESTING HABITS OF BIRDS

Birds That Do Not Sit. The mound builders and their allies (*Megapodes*), native to the hotter parts of Australia and the islands to the north of that continent, resemble reptiles in the fact that they do not incubate or sit upon their eggs and hatch them out by the heat of their bodies. Some of them simply deposit the eggs in hot sand, while others, such as the brush-"turkey" (*Talegallus*), deposit them in a huge mound of dead leaves and other vegetable matter, the decay of which generates a sufficient amount of heat for the purpose. The young when hatched out are in a very advanced state, and quite capable of looking after themselves, in correspondence with the fact that the parents do not trouble their heads about them. The forms in question appear to be the least highly organised members of the group of game birds.



314. A SWAN'S COURTSHIP
Photographed by Prof. B. H. Bentley

Care of Eggs and Young. All other birds incubate their eggs, and take more or less care of their young. Even the much maligned African ostrich takes some pains in this direction. A number of females scrape out a hole in the sand, and the necessary heat is supplied by the sun during the day and the cock-bird during the night.

Protective Colour of Eggs. It may be remarked in general that eggs which are simply laid on the ground, or in a more or less careless nest in this position, are protectively coloured, and often very difficult to detect on that account. The young run from the egg, and are also protectively coloured. In cases where the nests are cunningly hidden, or situated in inaccessible places, the young are helpless nestlings. Here too, as a rule, but not always, exposed eggs are protectively coloured, while those completely hidden from sight are generally white or pale in hue.

The colours of eggs, however, still require a great deal of investigation, and if many amateurs who at present are merely egg-collectors would seriously turn their attention to the relations of colour to surroundings, their labours would in all probability be amply rewarded. Some of our natural history societies are doing good work in explaining the meaning of structure, form, and colour with reference to habit in various animal groups, and if all would combine to this end much might be accomplished. Simple naming and collecting are waste of time, except as a preliminary to serious research of the kind indicated, or with reference to distribution and general questions of this nature. The student will find our natural history museums, now established in most towns, of the greatest value and assistance in his researches.

Some of the plovers simply lay their eggs among shingle or in stony places, and these are so like mottled stones as to deceive all but very experienced observers. The chicks have an interesting habit of squatting when alarmed, when they become quite as inconspicuous as the eggs. All those who take a special interest in the nesting habits of birds, and have the opportunity, should carefully examine the splendid collection of eggs and nests in natural surroundings contained in the Natural History Museum at South Kensington, an institution which in this and many other directions illustrates the romance of science in an unusually striking manner.

Some Examples from Nature. The common sandpiper (*Totanus hypoleucus*) constructs a careless nest, containing four protectively coloured eggs [**293**], in the neighbourhood of gravelly streams. The series is here completed by illustrations of the adult bird incubating the eggs [**294**], and the protectively coloured chick [**295**] four hours after hatching. Even more interesting are the illustrations of the black-headed gull. First we have the rough nest with three eggs [**296**]; then the same showing the young birds beginning to chip the egg, probably a unique photograph [**297**]; next the partly hatched and protectively coloured brood [**298**]; and lastly a young chick facing an unsympathetic world [**299**].

Materials and Positions of Nests. The yellowhammer constructs a hair-lined nest on or near the ground [**300**], while that of the blackbird is lined with grass, and usually to be found in hedges a few feet above the ground [**301**]. The hedge-sparrow lays her clutch of bluish eggs in a cup-shaped mossy nest, lined with hair and down, and placed in the recesses of a hedge [**302**].

The nest of the greenfinch, constructed of twigs and wool, and lined with hair, is to be found in high hedges [**303**]. That of the garden-warbler is to be seen among bushes in gardens, and is constructed of grass, lined with finer materials of similar kind [**304**]. In small trees and bushes, near open spaces, may be discovered the nests of linnet and lesser redpoll. The former [**305**] is made of twigs and moss, lined with wool, hair, or feathers, and the latter [**306**] of twigs and grass, lined with down.

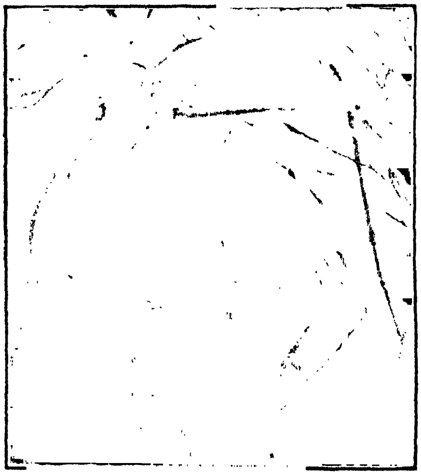
The beautiful hair-lined mossy nest of the sedge-warbler (*Acrocephalus phragmites*) is lined with hair, and either actually suspended among sedges or built in bushes adjoining the water [307]. Another type is presented by the nest of the song-thrush, generally placed in hedges, and lined with mud. Illustrations are given of a nest of eggs [308] and an advanced brood [309] of this bird; also of a fledgling [310] belonging to an allied species, the missel-thrush.

Well-built Nests. A distinct architectural advance is seen in the tree-nest of the chaffinch, exquisitely made of moss, lichen, and fibre, lined with hair and down [311 and 312]. In this, and many other elaborately woven homes, the sticky saliva is used as a cement. From such a case we may pass to such a beautiful domed nest as that of the long-tailed tit (*Acredula caudata*), where a roof is added to the cup-shaped foundation.

Some of our birds of prey build stick nests with a softer lining, and a careless structure of similar kind is constructed by the wood-pigeon, the white eggs of which may be clearly seen from below through the interstices. The black, ragged nests of the social rook are of similar material, more closely compacted together. Similar, too, is the nest of the magpie, commonly to be found in thorn-bushes, for greater security.

Communal Homesteads. The picucules, or tree-creepers, of South America build nests of the most varied kind, among which are those of the oven-bird (*Furnarius*). These are of clay mixed with fibre, and a sort of antechamber leads to an inner compartment, where the eggs are laid upon a layer of grass. Much more remarkable than these, and probably the most extraordinary outcome of bird architecture, are the communal grass nests of the sociable grosbeak (*Philhœterus socius*) of Africa, in which from one to three hundred pairs combine to produce a compound structure, built round the trunk of a tree, and covered with a common roof, so as to suggest a gigantic mushroom in appearance.

Edible Birds'-nests. The clay nests exemplified by the oven-birds suggest those of similar material constructed under the eaves of barns and the gables of houses by the house-martin, and shaped like half a saucer. The clay pellets are cemented together by saliva. Similar in shape are the edible birds'-nests of the East, but these are entirely made of hardened saliva. They are constructed by swifts, and are highly valued by the Chinese as an article of diet.



315. PIPIT'S EGGS AND ONE CUCKOO'S EGG
Photographed by Prof. B. H. Bentley

The Indian tailor-bird actually sews leaves together into a funnel-shaped nest, and the fan-tailed warbler stitches grass-stems together above its globular nest. It is even said to make a knot in the end of the thread.

Some birds prefer to lay their eggs in places far removed from sight. The sand-martin, for instance, digs out a tunnel in a sandbank, and brings up its young at the end of this upon a bed of down. Somewhat the same is true of the kingfisher, but here the bed is made up of disgorged fish-bones.

Homes Dug Out of Trees. Woodpeckers excavate a cavity in the trunk of a tree, and lay their eggs at the bottom of this, while the nuthatch uses a ready-made hollow for the purpose, and contracts the opening with mud, leaving only just enough space to serve as a door. One of the most extraordinary instances of nesting in a hollow tree is afforded by some of the hornbills of Africa and Asia. Here the hen-bird is actually built in with clay, probably by her mate, who at any rate feeds her with the greatest devotion during the enforced seclusion.

Feathered Foundlings. We have, lastly, the curious habit of brood-parasitism, exhibited by the cow-birds of South America and our native cuckoo, which deposit their eggs in the nests of other birds. These eggs are apparently, at least in the cuckoo, not laid in this situation, but carried there in the beak of the hen-bird. The hedge-sparrow and several other of our native perchers are victimised in this way. An illustration is appended of a cuckoo's egg in the nest of the meadow-pipit [315]. The young cuckoo develops more quickly than its unfortunate foster-brothers and sisters, whom it ousts from their legitimate home, shoving them over the edge of the nest to perish. In this inhuman proceeding it is aided by a hollow between the shoulders, which later on disappears. The misguided foster-parents tend the unnatural guest with the greatest assiduity, and have hard work to satisfy its inordinate appetite. The intelligence of birds obviously has strict limitations.

The eggs of the cuckoo undoubtedly vary a good deal in appearance, and it has been asserted that they commonly resemble those of the particular species selected as a victim. This is, however, extremely doubtful, and certainly not supported by the photograph from nature here given.

ADVANCED VIOLIN PRACTICE

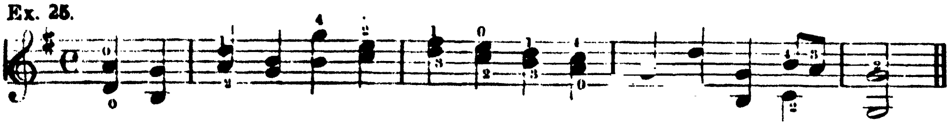
Tartini Notes. Graces. Trills. Solo and Double Shakes. Vibrato. Harmonics. Pizzicato Effects

By ALGERNON ROSE

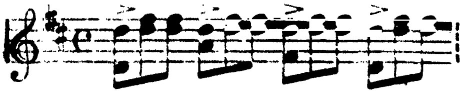
BY this time the drudgery of practice should have disappeared. The player will now seek to extend his time of study, being stimulated by the delightful delirium he experiences as progress is made. This pleasure, however, will depart if he does not continue his self-discipline and adhere to his plan of regular and methodical practice. The fact that, whenever a brilliant violinist appears, he, or she, is proclaimed the disciple of some great teacher need be no discouragement. Whoever excels on the violin is indebted more to himself than to the supervisor of his studies. The most expensive master can only point out the right way. He cannot infuse a divine talent into a dull pupil. When there are so many excellent "methods," the danger is that the student, intent on treading too much in the well-worn footsteps of others, may neglect and lose the ability to analyse his own weaknesses and remedy them by compiling—after studying the course on Theory—his own exercises, as many great fiddlers have done in their youth.

In double stopping the student should endeavour, by bestowing great care on the fingering, to get the intervals well in tune. The bow movements in octave passages, and so forth, are effected solely by the wrist, which is helped by slightly raising or lowering the elbow. Listen attentively to each combination of sound. Many violinists who play single notes well in tune are not so successful in double stopping. When they first began this department of study they did not take the precaution to compel their fingers to press the strings at the right points. They failed to realise that the chief difficulty, as well as the chief charm, of double stopping is correct intonation. Thus they contracted a bad habit of making false notes, and lost their perception of the dissonance. This addiction, having taken root after constant repetition, is almost impossible to cure. It therefore repays the student to be very careful at the beginning.

Ex. 25.



Ex. 26.



Tartini Tones. In a good violin, when two notes are played in tune together, those sounds are supplemented by another given from the body of the instrument itself. It is deeper than the notes bowed, and resembles the "hum-tone" of a bell which accompanies the "strike-tone." Such resultant harmonics in the violin are known as the *Tartini* tones, so named after the great violinist who first drew attention to them. If this third sound is not audible, it is an indication to the student that his stopping is wrong. Therefore, in practising double stopping, do not listen to the top note only; give more attention to the lower sound. The outline, or melody note, is more capable of taking care of itself. Presumably it is the ambition of the student to prepare himself to play later on some of the most beautiful violin music with instrumental accompaniment. In such compositions he will find double stopping used mainly in cadenzas or flourishes. Meanwhile, the other instruments have a pause of silence. If his intonation is good, his skill will be displayed to advantage; if bad, there will be no kettledrum to hide his defects. The ear of the player can not, therefore, be too scrupulous when learning double stopping. If out of tune, an audience will immediately detect the error, especially in octaves. Playing major and minor scales in thirds is an excellent training in order to get the intervals clearly in succession without using the open strings. The chief trouble is to put the second and fourth fingers into their correct positions, according as the intervals are major or minor. It is of more use to learn to play one scale correctly in double-stopped thirds than to be able to stop all the other scales indifferently.

With a little thought, many helpful exercises [see Ex. 25], to give variety to practice, may be made by the student himself. Ex. 26 is another useful exercise, quoted from Spohr.

The Graces. We now come to the graces, or embellishments. Of these the chief are the *shake*, or *trill*, the *turn*, *mordent*, *appoggiatura*, etc. When "plain," the shake is produced by a simple alternation of two single or double notes executed rapidly. This is easy to do badly, but very difficult to do well. What is called by the Italians a *catena*, or chain, is a succession of shakes. Think of a long trill of a singing bird on successive notes. Try to imitate its clear and even effect. Begin slowly, and increase the speed gradually. When the fingers tire, leave off, and begin again later. When an appoggiatura precedes the note to be trilled, and it ends with a turn, the shake is called "prepared." In the upper positions of the fiddle, where the notes come very closely together, the student should be careful not to make the sound too sharp.

Trill Practice. Trill practice strengthens the fingers. It makes their lowest joints responsive, and gives to them the independence necessary for good violin playing. Great violinists know this ; their trill exercise never ends.

Such finger drill can be done without a violin. Place the left thumb against the tip of the first finger, then strike the tip of the second and third, or third and fourth fingers against the palm of the hand. Make the tips strike as far down towards the wrist as possible. Regulate each stroke by the ticking of a clock, or, if in a railway carriage, by the motions of the vehicle. Make the strokes forcibly. Keep the unemployed fingers rigid. As the finger muscles get stronger and more independent, increase the number of strokes to each tick, or the sound by which the practice is regulated. To increase the power of the troublesome little finger, put together the tips of the thumb, first, second, and third fingers. Then make the fourth finger wag backwards and forwards as far as it will go. The motions should be done with regularity and increased velocity day by day.

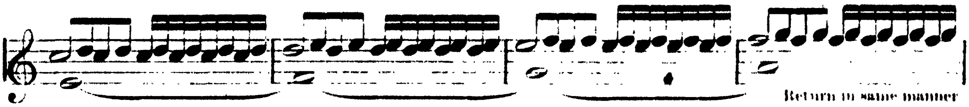
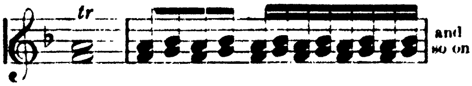
Ex. 34. SHAKE combined with DOUBLE STOPPING



Ex. 35.



These drills are useful for acquiring that finger-freedom which is indispensable in making a good shake. But such exercises must not be done erratically. After practising at odd moments for a week away from the violin, try the shake on the instrument itself. Record the velocity attained ; then continue this independent shake practice. Test the progress made at the end of the second week, and so on. The beats in every shake must be equal. Each finger should be raised high, and descend on the string like a little hammer ; but the fingers must go down freely. In trills by semitones there should be no rubbing of one digit against its neighbour. It is useless for the student to think that he can learn the shake in a day. Unnatural force should not be used, and over-exertion must be avoided. There is no better practice than to convert each scale into a chain of shakes. [See Ex. 27.]

Solo Shakes. Never use the first finger during practice in a single shake. Pay particular attention to exercising the little finger. In a solo the shake should always be given its full value in time. To render it as brilliant as possible good players sometimes begin a shake half a beat before the time indicated in the music. The student should devote at least a quarter of an hour every day to playing one or more scales up and down the fingerboard with the slow shake at first, increasing the speed gradually. This may appear wearisome unless the self-instructor remembers Samuel Butler's words that "Drudgery and knowledge are of kin." The latter cannot be gained without paying its price, and this is the surest way of obtaining brilliancy and power in fiddle playing. If knowledge is worth having, aspire to get it completely. Do not be retarded by wasting time over alluring and unprofitable tunes. Such are to be found in many violin methods. These pills, to help the learner, are often so highly sugared that the object in swallowing them is misunderstood, although that should be the first consideration. The learner who cultivates the ability to write out his own exercises can practise the shake in a different way each day.

Turns. Having conquered the shake with single notes, the smaller ornaments will be found easy. The *direct turn* consists of three or four little notes preceding or following a chief note. These are played by the same bow which takes the chief note. [See Ex. 28.]

If the turn is *inverted*, it is marked as shown in Ex. 29.

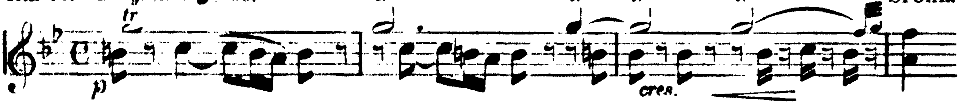
A *single mordent* is a sharp alternation of the note to be played with the semitone above. The word comes from the French "mordre"—to bite. [Ex. 20.]

When two such signs occur over a note two bites occur before the note is emphasised, the ornament then being called a *double mordent.* [Ex. 31.]

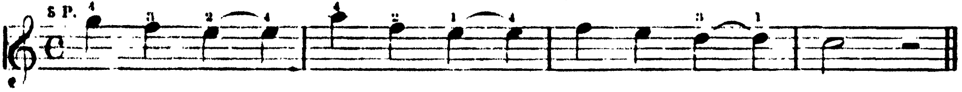
The *appoggiatura* is a little grace-note, either long or short, literally "leaning," or resting against a full-sized note. It does not interfere with the time of the music, the two notes being executed with the same bow in the space allotted for the second. [Ex. 32.]

Lastly, the *acciaccatura* (or "short appoggiatura"), meaning to crush, is a little note with a stroke across its tail, preceding a full-sized note. The former is fingered so quickly that it almost appears to tumble into its neighbour. [Ex. 33.]

Ex. 36. *Larghetto.* ♪ 80. SPOHR.



Ex. 37. CHANGING THE FINGER



The Double Shake. These minor embellishments lead us to the consideration of that extremely difficult ornament the *double shake.* As a preliminary exercise, the pupil is advised to return to the double stopping in sixths, and make a single trill alternately on the top and bottom notes while keeping the bow on both strings. [Ex. 34.]

Now practise making chain shakes with two notes together in thirds, and see that they are in tune. If not, they will be offensive. Begin slowly, listening to make sure of the intonation. Make the beats equal, and increase the speed gradually. On the lower strings shakes are not taken so quickly as on the high ones, owing to the slower vibration. To be effective the shake must be executed literally with "grace." It should be interpolated in a melody with lightness without disturbing the time. Double trills which employ open strings have no turn at the end, We give a useful exercise, which should be continued for two octaves, up and down, and transposed into other keys. [Ex. 35.]

The most difficult of all shakes on the violin is that which necessitates the playing of an accompaniment at the same time, so that the effect is as of two performers instead of one. In the first place, the fingers which execute the shake must move with the greatest rapidity and regularity; in the second place, the notes of the accompanying part have to enter as precisely as they would do if attention were concentrated on them alone. Ex. 36 illustrates what is meant.

Vibrato. If Stradivarius, before making a fiddle, had to wait five or six years while the wood of the belly was being dried naturally in the air, protected from sun and rain, it is only fair that the player on such an instrument, who is desirous to excel, should have to exercise his patience for a considerable period. Although unsuccessful at first in controlling the finger sufficiently to master the foregoing exercises, they will appear easy to the student if he goes back now to some of his earlier tasks. To each note of a simple exercise the learner should strive to impart a tremulous or impassioned quality of tone. It is the accomplished violinist who can render the simplest tune most beautifully.

The effect known as the *vibrato* is caused by making each finger in succession throb on the string by increasing and lessening the pressure of the finger-tip. The motion which alters the stopping should be very slight, so as not to interfere with the purity of the tone. Practise slowly and steadily at first. Devote ten minutes to this study every day till the vibrato can be produced easily. Give special attention to the weak third and fourth fingers. A long, sustained note may be rendered very beautiful by beginning with the vibrato, slowly and gradually increasing its speed. In old music this effect is sometimes indicated by dots, thus . . . . . Nowadays it is left to the discretion of the player.

It may be noticed that the vibrato is used in four distinct ways. First, it is done quickly, for giving a strong accent to a note. Secondly, it is used for sustaining slow notes in an emotional manner. Thirdly, the vibrato is begun slowly and then quickened, so as to make a crescendo on a long note. Lastly, it is begun quickly, and the throbbing is retarded to make an effective diminuendo.

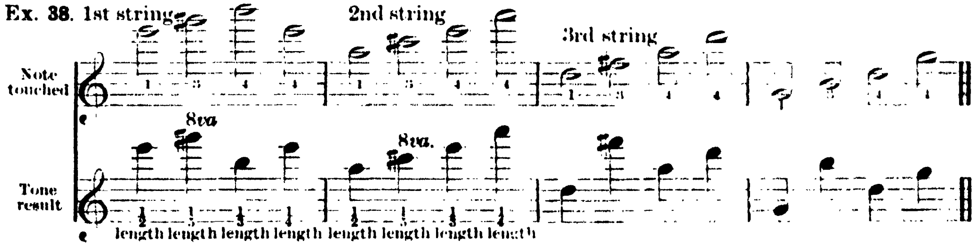
Tempo Rubato. A refinement of effect in the ingratiating use of the vibrato is a temporary acceleration, or retardation, of the time. This is termed *tempo rubato* (or "robbed time"), when some notes are deprived and others given more than their share of the strict time indicated. But these liberties, although occasionally allowable in solo playing, should be avoided by the student who is preparing to take his place in an orchestra.

Changing the finger on the same note during the same bow is another device for imitating the human voice. Singers know that, when two syllables of a word spelt differently are sung on the same note with the same breath, the expression of the second syllable is slightly different to the first, the reason being that different vocal cords are employed for their enunciation. Almost an identical effect is elicited from a violin string when the second of two notes linked together is stopped by a different finger. However equal the strength of the fingers may be, there is a subtle change in the tone.

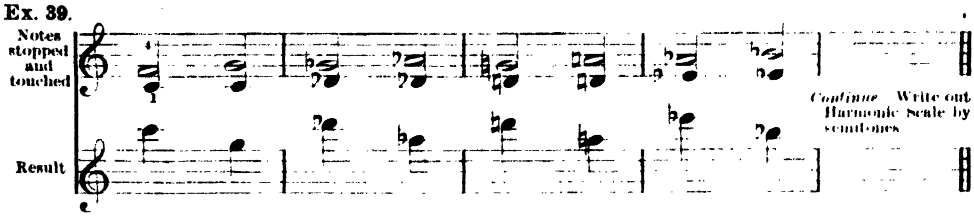
The student should now turn to Ex. 37.

In the first bar the second finger is drawn back to C in the first position, so that the fourth finger falls down without any gliding sound. This power of inaudibly altering the fingering of one note is important. Success in portamento playing often depends on it. While the change takes place the bowing must be continued delicately, so that no difference in quality can be detected, especially if, in order to continue the same sound, the string as well as the fingering is changed.

Ex. 38.



Ex. 39.



Continue. Write out Harmonic Scale by semitones

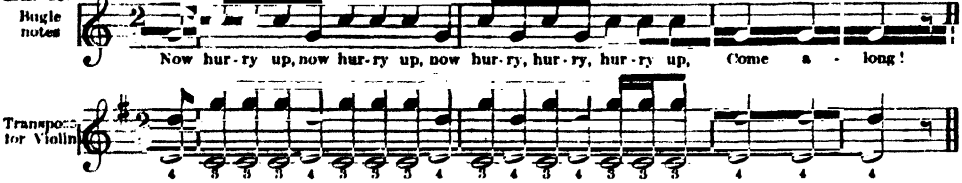
Harmonics. If the violin in finger-changing is capable of closely imitating the singer, it transcends the human voice in another respect. A few accomplished singers with phenomenal range have been able to produce very high vocal notes of a pure and fluty quality, but every violinist can elicit such sounds in greater variety after a little practice. If the fingerboard of the violin is regarded, it will be observed that the free vibration of each string takes place between two fixed points—the nut and the bridge. Now, touch the E string lightly with the first finger half-way between these points. Bow the note softly. The sound heard will be an octave above the pitch of the open string. In quality it is clear and beautiful. In the same manner the string can be made to divide itself into vibrating segments of 3 thirds, 4 fourths, 5 fifths, 6 sixths, and so on. But such sounds are produced most easily from the G string, because it is the deepest in pitch. They are known as *Harmonics*. It was Paganini who first astonished the world by his marvellous employment of harmonics. His rivals regarded the innovation as "claptrap." To play harmonics with facility, the finer the points of the fingers are the better. Thick, stumpy fingers are not well adapted to such work.

Natural Harmonics. In a full-sized violin, half the free length of the E string will be found about 6 in. from the bridge. After touching this point lightly with the first finger, and getting the octave E on the first string, with the fourth finger find that point which measures off one-third, approximately 4 in., from the bridge. Bow lightly. The resultant sound will be B, a fifth above the harmonic E. Measure off with the third finger that point between the centre and third segment, indicating one of the quarters of the whole, or about 3 in. from the bridge, and find that note which gives the double octave of the open note.

But the finger can be placed lower down the finger-board so that it rests over a corresponding lower third—8 in. from the bridge—or second fourth division—9 in.—of the string. The harmonic obtained will be like that at the upper third or upper fourth division, but less clear. By dividing the string into five parts, four similar harmonics can be produced at any one of the notes. They give the double octave of the third of the open note. This ability to choose either position is useful in fingering. That harmonics can be fingered from either end of a fiddle-string may puzzle the student. He has been known to argue that, if he touches the string higher up or lower down, he lessens the vibrating segment. Quite so, if his finger presses the string firmly. But he does not "stop" a note when producing a harmonic, although, touching lightly at a natural point, the whole string continues to pulsate. What is altered are the divisions, or lengths, of the vibrating segments, when the string is partially damped above certain nodes. This causes the higher "partials" of the strings to assert themselves and sound their clear overtones. [Ex. 38.]

Artificial Harmonics. The foregoing harmonics obtained from the open strings are termed natural, as all harmonics, of course, must be. But when the first finger forms a new nut by stopping the strings firmly, and a disengaged finger lightly touches a node above, the harmonic is called artificial. Place the first finger down firmly on C (first ledger line below staff). Let the fourth finger rest very lightly on the position of F, a perfect fourth above the note stopped. Bow the string softly. Instead of F the sound will be C, two octaves above the C stopped by the first finger, because, above the new nut, the shortened string yields the harmonic natural to it. Keeping the first finger in the same place, stretch the fourth lightly over the point for G above the F. The tone will now be G, an octave and a fifth above the note stopped. Practise both the first and second methods of harmonic production. On the G string, a stronger bow can be used than on the gut strings. Extend the series up the scale by semitones the length of an octave. [Ex. 39.]

Ex. 40.



Bugle notes
Now hur-ry up, now hur-ry up, now hur-ry, hur-ry, hur-ry up, Come a - long!
Transpose for Violin

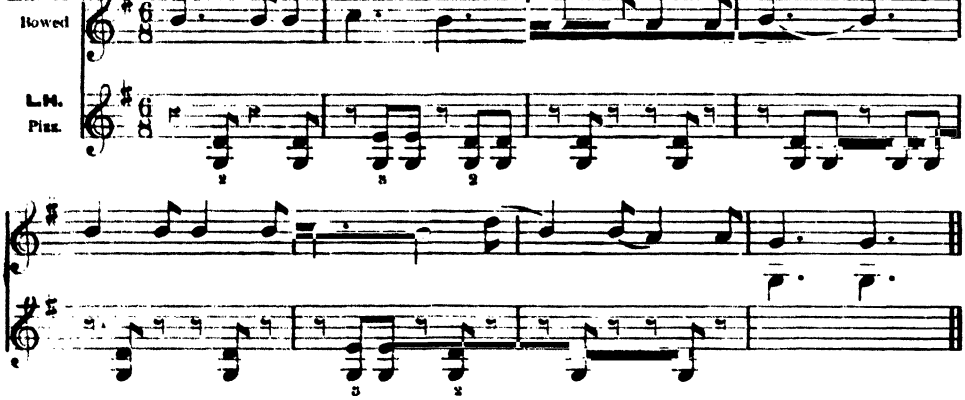
Ex. 41.



Excellent practice can be obtained by transposing Army bugle calls a fifth higher, and imitating them. [Ex. 40.]

Con Sordino. "Sordina," or "Sordino," is the Italian for what we call a violin "mute." The effect, however, is not to render the instrument dumb or silent. It is rather that known in singing as the quality of the "bouche fermée," or shut mouth, when the vocalist closes the teeth and almost the lips. In other words, the violin hums. Its tone is thus diminished when a little extra bridge is fixed over the real bridge of the fiddle, or a penny is inserted between two strings behind the bridge. The quality of sound thus obtained is mysterious and mournful, for which reason the mute is often employed in slow pieces of a pathetic character. When the words "con sordini" or "con muta" occur in the music the mute must be put on. It is taken off when the indication "senza sordino" is reached.

Pizzicato. Pizzicato effects for the left hand are got by plucking one or more strings quickly whilst usually bowing another string. Thus, if all four fingers are stopping the second string in the first position, and the fourth finger twitches the string, the note D, stopped by the third finger, is sounded. If the third finger then twitches the string, C, stopped by the second finger, will sound, or if the second finger twitches, the B, stopped by the first, will be heard. In ascending a scale, the operation is reversed by the stopping fingers being put down instead of taken off. The fourth finger then usually does the plucking, so that the point of contact may be as far away as possible from the place where the sound is checked, the effect being best when the twanging is done by the finger farthest away. [Ex. 41.]

Continued

BRICK AND TILE WORK

Various Classes of Brickwork. Brickwork for Other Trades. Dealing with Old Brickwork. Underpinning in Brickwork. Brick and Tile Paving

Continued from page [illegible]

By Professor R. ELSEY SMITH

Air Flues. Flues for conveying air into or out of a building in connection with its ventilation are often required. These may vary from large air ducts, in the case of the main flue of a large building, to a small flue formed in the thickness of a wall. The large duct is formed with brick sides and very frequently with a concrete floor and ceiling, and the walls may, if necessary, be plastered. Smaller flues are often formed in the thickness of the wall in the case of inlets, and should be formed without sharp bends or angles where possible, and should, if possible, be rendered [115]. Extract flues are sometimes carried up in the same stacks as chimney flues; in other cases several are gathered into horizontal ducts and thence taken to a vertical flue or upcast shaft, resembling a small factory chimney, which is usually fitted with some mechanical appliance for extracting the air. [See Ventilation.]

Forming Chases in Brickwork. It is often necessary to form a vertical recess in the face of a brick wall, to receive a rain-water pipe on the outer face, or one or more lead or iron water pipes internally. Where such chases are required it is desirable, when possible, to form them in building the wall, both the depth and width of the recess being the multiple of half a brick; but, especially in the case of internal pipes, it is not always possible to foresee where they will be required, and chases must then be cut; strong chisels are required, and the bricks are cut by driving the chisel into the brick and levering out the brick required to be removed. It is undesirable to cut brickwork that is newly erected, or, as it is termed, *green*, for this is liable to shake the wall and disturb the brickwork all round.

Chases may be formed for the most part wherever they are required; but a chase may not be cut in a party-wall so that the back of it comes within 4 in. of the centre of the wall, and they should not be cut close to the angle where two walls are joined. A chase that has been cut in this way will always be somewhat rough on the cut surfaces, but may be rendered, if required, to have a smooth surface.

Perforations in Brickwork. Perforations are also required for many purposes in brick walls, as, for example, where the pipe from a w.c. or sink has to be passed through the wall from the interior to the outside. Such perforations are cut with chisels similar but of greater length, where thick walls have to be dealt with. Where the brickwork is old and of good quality the process may be very laborious; the perforation is made larger than the size of the pipe, and the opening is made good with new brickwork after the pipe is in position.

Building-in and Pinning-in Stones. Very frequently it is necessary to insert in brick walls blocks of stone, which form the sills of window openings or the steps or thresholds of door openings. These may either be *built in* as the wall proceeds, if they are prepared, or may be afterwards *cut and pinned in*. In the first case the stone is placed in position when the wall has been carried to the proper height to receive it, and a bed of mortar is placed under each end, but it is usual to leave the centre of the stone without any mortar bed. This is termed *hollow bedding*, and the object is to permit the stone more freedom of movement if a slight settlement in the wall should take place, which may often prevent a fracture. When the brickwork is pointed down, on completing the work, all such hollow beds must be carefully filled with mortar, which is worked well into the back of the bed with the trowel. After the block of stone is bedded the building of the wall is continued, the brickwork being cut and fitted round the two ends of the stone.

Where a stone has to be cut and pinned-in the brickwork is cut away as far as is necessary to receive the ends of the stone, which is placed in position on a prepared mortar bed, and the brickwork is made good all round the stone, the cement mortar being forced in between the upper surface of the stone and the brickwork above; where the brickwork has had time to settle thoroughly before the stone is pinned in, hollow bedding need not be resorted to.

Forming Sand Courses. In the case of stone staircases in which the ends of the steps have to be built into brick walls, and where the steps cannot be built in, it is usual to bed the bricks forming these portions of the wall that will be required to be taken out to receive the end of each step in sand instead of mortar. This allows the wall to be carried up above the sand courses, but permits of the bricks so laid being withdrawn without shaking the wall. It is, of course, essential that the position of all steps to be provided for in this way should be accurately set out, and the steps when inserted are pinned-in in cement mortar, and the brickwork made good round them.

Building-in Iron and Timber. The ends of iron bars are sometimes cut and pinned into brickwork, but this does not give a very good fixing, and, where possible, it is better to let the ends of such bars into blocks of stone built into the wall. This course is usually adopted in all cases in which a considerable strain is placed upon the ironwork, as in the case of the hooks for hanging large gates.

The ends of timbers should not be built into brick walls, as they are apt to decay, but there should be formed, to receive the ends of all such timbers, a recess which will allow a free circulation of air round them.

Preparations for Fixing Joinery. Wherever joinery is required to be fixed, in brick openings or against the face of brick walls, preparation for its proper fixing must be made. A method formerly in vogue, but much less used now, was to build in at intervals wood blocks the size of an ordinary brick; but it was found that such blocks are apt to shrink, become loose, and therefore be unreliable, and in place of them similar bricks made of fine breeze concrete are now used. These are not liable to shrink, and give excellent fixing for nails and screws, but care must be taken if two adjoining faces are exposed giving a salient angle, not to split the brick in driving in nails. Another method is to build in wood slips. These are thin layers of wood the same size as a brick, about ⅜ in. thick, and are inserted between two bricks in place of a mortar bed. Being thin, they are not liable to shrink appreciably, and are firmly held by the weight above them; but care is required in fixing joinery to them not to split them. Another method which answers admirably for fixing solid frames is to build into the brickwork iron *holdfasts*, one end split and turned up and down, or else split and spread outwards, the other end bent down and tapped for a screw [116]; this end is left exposed in the face of the brickwork, the frame is fixed by means of a screw to it, and the head of the screw may be counter-sunk. [See Joiner.]

Position of Fixing Blocks. Whatever the means of fixing adopted, points for fixing should be provided in all openings within 12 in. of the top and bottom, and at intermediate points not more than 18 in. apart, and in the case of dadoes, rails, etc., not more than 3 ft. apart horizontally, or more than 18 in. vertically. Where joinery is to be fixed to an old wall the bricklayer must cut a series of holes at similar intervals, into which the joiner drives wedges of hard wood, which are cut off flush with the face of the wall or of the plaster.

Bricklayers' Work for Other Trades. The bricklayer usually beds all wood plates and lintols supplied by the carpenter—*i.e.*, he lays on the surface of the brickwork which is to receive the plate an even bed of mortar on which the plate is laid and levelled. He also beds or builds-in templates, corbels, or brackets of stone supplied by the mason, or of iron supplied by the smith. He also beds door and window frames, and points all round them between the frame and brick reveals in cement; sometimes screeds are formed against the back of the reveals to receive the face of the joinery to be fixed, and this is usually done in mortar formed of one part of lime to three of sand, with the addition of 1 lb. of clean bullock's hair to every 2 cub. ft. of lime, to give it cohesion, as in plasterers' work. [See Plasterer.]

Altering Old Brickwork. The method of toothing new work to old has been already described [page 2268]. Another operation that is frequently necessary is the cutting of a new opening in an old wall. If the brickwork be sound in character, and the opening of moderate size, say 5 ft. or less, the opening may be cut away without any fear of collapse or settlement. An arch, with or without a lintol, is thrown across the opening as for a new arch, and the brickwork above made good to it; the jambs are also, in many cases, rebuilt, or at least refaced. If the work is not sound in character, special care must be exercised, as the cutting away is apt to shake the wall. When possible, a portion of the thickness only, say one-half, should be cut away, the new arch or lintol inserted under this portion, and the whole made good before the other portion is dealt with. If the opening is a wide one, and a girder or bressummer is to be inserted to carry the upper part of the old brickwork, the upper part of the wall is first carried on needles [see page 918], the brickwork is cut away as required to form the opening, and the new girder is then put into position and supported on iron stanchions or storey posts, or by brick piers erected by the bricklayer. When in position, the upper flange is covered with a thick layer of cement mortar, on which slabs of stone are bedded, equal in width to the thickness of the wall above. On these stones a brick wall is commenced as already described, and is built up to the underside of the old brickwork, but no footings are necessary; the work is carefully set out and finished, so that it will support the under side of the old walling, tiles or slates bedded in cement being employed to make up any height that will not accommodate a full brick course. All such work is executed in cement mortar, and the process of finishing the new work tight up under the old, which involves a process of carefully filling in the last joint with mortar from the face of the wall, is termed *pinning-up*.

Underpinning in Brickwork. In underpinning an existing wall in brickwork, the process is, in some respects, similar to the last. A short description of the general process and particulars of the excavator's work was given on page 335. The illustration [114] shows an end wall of a building the foundations of which are to be carried down to a depth 5 ft. below their former level. The necessity for this may be due to a failure of the earth below the old concrete, or to provide increased height for a basement. In the first case the old wall will have shown signs of failure, and will have to be shored before the foundations are touched; in the latter case, if the ground be solid in character, the work may be executed without this preliminary in many cases; but judgment and experience alone can determine in any particular case which course to pursue.

The pier A or the piers A and E would, in most cases, be first dealt with. An excavation large enough exactly to receive the new concrete block is made to the necessary depth, and the sides are well timbered [page 330], and the concrete bed inserted, and allowed to set.

The bricklayer, after the new concrete foundation of the first pier or set of piers is in position, sets out the new footings on the top of it, with due regard to the position of the old brick walling to be supported, and erects his wall. This is built of the same length as the concrete foundations, and in erecting it a toothing is formed at the end to receive the intermediate lengths; at the top the wall is pinned up tight against the old one. In constructing other lengths of the wall subsequently, such as the angle pier E, if not carried out at the same time, and the central pier C, care must be taken to preserve the proper horizontal alignment of the different courses, so that when the intermediate portions, B and D, of the wall are built, the whole will bond properly, and form in effect, when completed, a homogeneous wall, properly bonded, and with regular and horizontal courses, and to ensure this, a *storey-rod* [114], consisting of a strip of board in which the courses are marked, should be employed, especially if the underpinning be of considerable depth.

Brick Paving. Brick paving [117] is used in various forms. Ordinary stock or other forms of brick may be employed, and laid flat or on edge, and are used for paving coal-cellars and similar positions where there is not much or heavy traffic; they may also be used around the outside of the building to form channels, which are sometimes employed to help in keeping the building dry, and for yards when the traffic is not heavy. In other positions subject to much wear and tear, as in the case of coach-houses and stableyards, *clinkers* [page 1948] are much used for paving. Staffordshire blue bricks of special form [118] are also frequently employed, their edges being chamfered to give a reliable foothold for the horses. Some form of hard bed should be provided to receive this paving. It may consist of hard dry rubbish, well rammed or consolidated with a heavy roller; but wherever hard bricks are used, and a thoroughly reliable floor is required, without any liability to become uneven with wear, a good bed of cement concrete at least 6 in. thick should be provided, and the ground below it should be previously well rammed or consolidated.

Laying Pavings to Falls. The floor of any uncovered yard must not be laid perfectly horizontal, or water would lodge on it and not run away, but the surface should be inclined, so that any water will run off to one or more convenient points, where it may be carried off by a drain. This fall should be formed in the concrete bed. This work is described as *laying the concrete to falls*, and requires careful setting out and levelling to ensure that the paving shall at no part be hollow, thereby retaining pools of water. The concrete is usually finished with a floated face in Portland cement and sand, to give an even bed for the bricks. These are bedded in cement mortar; the vertical joints may be filled with mortar as the bricks are laid, or may be kept fine, and when the floor is laid, either dry cement is brushed into the joints, or grout, consisting of cement and sand mixed with an excess of water, is brushed over the floor so as to

118. PAVING BRICK WITH CHAMFERED ANGLES

119. TILE PAVING

AIR FLUES, HOLDFASTS, AND PAVING

In all cases in which the finished surface is of an ornamental character, care must be taken in arranging any patterns that may be used, so as to centre with the spaces they are to occupy, and in adapting borders to any irregularities in the plan due to projections or other causes. This should be provided for in preparing the design, but the execution depends on the workman, and requires careful forethought and attention.

Tile Paving. Tiles are very largely used for pavings [119]. They vary greatly in thickness, size, shape, and colour; they may be of one plain colour throughout each tile, and throughout the whole floor, or tiles plain in themselves may be used in various colours to form patterns, or the tiles themselves may be of two or more colours. In places where there is no actual traffic over them—as, *e.g.*, in hearths—the tiles may have a glazed surface.

Tiles are laid on a floated face formed on a bed of concrete; they must be cut, if necessary, to fit irregular positions, are immersed in water for some time before laying, and are laid and jointed in cement. The cement bed should be about ½ in. thick to allow of any slight unevenness in the tiles being adjusted.

Mosaic and Marble Paving. Mosaic floors, whether of tile or marble, are set out on sheets of paper, the small cubes of which they are composed being temporarily fixed to the paper so as to form the required design. They are laid in sections upon the prepared bed, be at least 2 in. thick, and may be composed so far as the bulk is concerned of one part of Portland cement to four parts of small shingle free from salt, or of fine granite chippings, and finished with neat cement ¾ in. thick laid immediately after the coarser stuff, so as to set and become incorporated with it; or with crushed granite mixed with Portland cement, which is known as *granolithic paving.*

Channels and Gutters. If channels or gutters be required in any form of paving they must be prepared for in the concrete bed in such a manner that the full thickness of the paving can be formed at all points in the channel, and still give the required finished size for it.

Asphalt Paving. Asphalt is a good deal used for pavings. It must be prepared for like other pavings, and the surface on which it is laid should be thoroughly dry. It may be laid in any thickness from ½ in. up to 2 in., and if it exceeds 1 in. in thickness, should be laid in two coats, which is always desirable when it is required to be absolutely waterproof. It can be turned up against the walls in a continuous layer, which, in cases where water is liable to collect on the floor, is a great advantage. In road work the asphalt is sometimes laid as a powder and beaten with heated irons, but for floors it is more usual to heat the asphalt as for damp courses, and spread it while hot. [For wood block flooring, see Joinery.]

A STUDY OF TEMPERAMENT

A Psychological Explanation of Optimism and Pessimism. The Quality of Feeling. The Relation of Pleasure and Pain to Health

Group 3

PSYCHOLOGY

5

Continued from page 2374

By Dr. C. W. SALEEBY

Organic Optimism. Organic optimism is a term which the present writer has already employed elsewhere to indicate that more or less contented, happy state of mind, or state of the conscious self, which depends upon the health of the structures which are concerned with organic sensation. It might be called *gastric optimism*, in order to indicate the large share which sound digestion plays in it, or it may be called *constitutional optimism*. It might be argued that it is more a state of body than a state of mind; nevertheless, the condition of this organic sense of well-being is a never-to-be-forgotten factor of the state of mind at any given time. It is in consequence of this fact that every man in health, as the present writer has said elsewhere, has an *organic bias towards optimism*. Such optimism is, of course, entirely non-rational. It has nothing to do with beliefs or intellectual processes of any kind. We have already seen how, in disease, it is capable of completely outweighing a whole series of beliefs of the most horrible kind, or rather—and this is the all-important point—it may prevent a person from holding and realising those beliefs even when they are forced upon him; for instance, the belief that he has to be fed by a tube, cannot move any of his limbs, and is lying on a mattress in a padded cell. This is a state of affairs in which a perversion of organic sensation may permit a man to be radiantly happy.

Organic Pessimism. Now, it is the fact that a certain measure of organic optimism is the normal state of health; organic pessimism is a state of disease, just as an insane measure of organic optimism is a state of disease. In general, we apply the term *melancholia* to the pessimism witnessed in asylums. But it is, of course, a child's delusion that people can all be divided by a sharp line or by the walls of lunatic asylums into the sane and the insane. The present writer will put this question, which the reader will consider, and to which he may contribute an answer from his own experience—Is there any pessimism which is not really identical with the pessimism of melancholia, and if we examined, or were able to examine, the famous pessimistic writers of the past, such as the two Germans mentioned in last article (both of whom were, of course, admittedly insane) should we not find that the organic sense of well-being was depressed in every case? The answer, which is here strongly suggested as true, though it would perhaps be premature to dogmatise, is that *pessimism, as we know it in the history of thought, is invariably a morbid product*: nay, more, that it must necessarily be a morbid product. This must surely be so, since no one who feels the "glow of health" within him, no one whose organic sense of well-being is in a healthy state, can fail to see that though there is undoubtedly evil in the world, yet there is "much to be thankful for." Of that he has no doubt, since his own state of self-consciousness tells him so, of his own case, immediately and at first hand. It is submitted, then, on theoretical grounds as well as on the grounds that the history of literature and biography lead to the same conclusion, that pessimism is a morbid product.

Rational Optimism. It may further be argued that the facts which we have already cited lead fairly to a rational optimism—that is to say, an optimism which can be defended, not by saying "It is good to be alive, for I feel it so," but by argument and reason. The argument, in short, is that a happy state of mind is normal to health or to healthy life. On the whole, then, life is worth living. Take it on the very lowest ground, and even then we find that the normal exercise of the simplest functions of life—eating and drinking, walking, looking, and even other necessary functions with which the idea of pleasure is not commonly associated—are normally accompanied by a sense of satisfaction which essentially partakes, of course, of the nature of pleasure. Living beings, then, are so constructed that the exercise and functions of life, quite apart from obvious pleasures sought out and attained for their own sake, are yet worth living for. It is the constant amazement of those who are experienced to observe how invalids, whose life would appear not to be worth living, yet cling to it, and are unmistakably seen to derive pleasure from it, provided that the illness is not such as to have interfered with their *organic optimism*.

The Quality of Feeling. It is quite definitely known that there are nerves of pain in the skin, and these have a definite course through the body and within the spinal cord, which definitely distinguishes them from the nerves of touch, of heat, and of cold. But, on the other hand, sensations in general may have a quality which is commonly known as *feeling-tone*. This subject has lately been admirably dealt with by Dr. McDougall, of Oxford. He agrees with every one else that pleasantness and unpleasantness are the two most important forms of feeling-tone. We hear a sound or see an extremely bright light, or have some other sensation and, *in addition*, we may have a sense of pleasure or of pain. This feeling-tone is, in some way, dependent upon the sensations, as Dr. McDougall says, and it "is in a certain degree independent of sensation quality; for one quality of sensation may be at one time pleasant, at another unpleasant, and at a third have no appreciable feeling-tone. Thus, there is, as a rule, an *indifference point*, which varies very widely, not only for different sensations or different persons, but for different persons at different times."

Pleasure and Pain. It is a further very significant fact that different classes of sensation vary in this respect. Says Dr. McDougall: "The more specialised sensations have comparatively feeble feeling tone; visual sensations, even when very intense, are hardly so unpleasant as a nauseous odour, nor is a pure rich colour sensation so pleasing to most persons as a delicious odour. The organic sensations, excited by changes taking place in the viscera (the internal organs), have the most intense feeling-tone, and these sensations are generally so vague that the feeling-tone predominates over the sensations."

It is not possible to go much further than this in our analysis of the ideas of pleasure and pain. The reader will duly have correlated Dr. McDougall's remark regarding the intensity of the feeling-tone of organic sensations with what we have previously said as to their influence. But the general proposition that feeling-tone plays its greatest part in the oldest and most essential sensations must be very carefully pondered over. It is in accordance with the great demonstration of Herbert Spencer that pleasant states of consciousness make for life, and painful for death. It is the evolutionary treatment of the problem of pleasure and pain which, as in so many other instances, has enabled us to arrive at a solution. The Spencerian proposition is that, in the main, pleasures are beneficial and pains hurtful. Thus, on the whole, when living creatures seek pleasurable experiences and seek to avoid those that are painful, they are seeking the beneficial and avoiding the hurtful. Plainly, those which seek the pleasurable and avoid the painful must thus have an advantage in the struggle for existence over those which do not, and still more over those—if their existence could be conceived—whose tendencies were to seek pain and avoid pleasure.

Pleasure is Life, and Pain is Death. "Sentient existence," says Spencer, "can evolve only on condition that pleasure-giving acts are life-sustaining acts." Thus the fact elsewhere noted by Spencer that "pleasure somewhere, at some time, to some being or beings, is an inexpugnable element of the conception" of good originates in the very nature of sentient existence. "Pains are the correlatives of actions injurious to the organism, while pleasures are the correlatives of actions conducive to its welfare."

Indeed, we must quote from the "Principles of Psychology" a passage now classical: "If we substitute for the word Pleasure the equivalent phrase, *a feeling which we seek to bring into consciousness and retain there*, and if we substitute for the word Pain the equivalent phrase, *a feeling which we seek to get out of consciousness and to keep out*, we see at once that, if the states of consciousness which a creature endeavours to maintain are the correlatives of injurious actions, and if the states of consciousness which it endeavours to expel are the correlatives of beneficial actions, it must quickly disappear through persistence in the injurious and avoidance of the beneficial. In other words, those races of beings only can have survived in which, on the average, agreeable or desired feelings went along with activities conducive to the maintenance of life, while disagreeable and habitually avoided feelings went along with activities directly or indirectly destructive of life; and there ever must have been, other things being equal, the most numerous and long-continued survivals among races in which those adjustments of feelings to actions were the best, tending ever to bring about perfect adjustment."

What Spencer did not Mean. It will be evident to the reader that this is a view the reverse of which has been held by certain people in all ages. To Spencer's law there are doubtless many exceptions—none of which is, in fact, really an exception, but rather a higher proof of the rule. Nevertheless, men have inferred from them—that is, from the existence of mischievous pleasures and beneficent pains—the doctrines that in general pleasures are unhealthy and pains healthy. "They have assumed," to quote Spencer, "that we are so diabolically organised that pleasures are injurious and pains beneficial." "Though every pleasure raises the tide of life, every pain lowers the tide of life." "And though, as every medical man knows, there is no such tonic as happiness!"

This profoundly important psychological truth must not be perverted. It is far from meaning that we are always to avoid anything disagreeable and are always to give the rein to our desires. It certainly does not interfere with the doctrine "that it is good to abstain from certain forms of self-indulgence in order thereby to achieve higher and more enduring happiness."

Is Life Worth Living? Thus we are able, even without the aid afforded us by the modern experimental study of the physical effects of pleasure and pain, to answer the old question as to the balance between pleasure and pain in human life. We need not be guided, as most thinkers have been, by our organic sensation, declaring, according as it dictates, that pleasure outweighs pain, or the reverse. Since we know that the pleasurable is normally correlated with health, and that the painful brings disease and ultimately death—pain being none other than dis-ease—our question is answered. In a word, as every one knows, health and happiness are correlated. It is, indeed, a necessary part of the constitution of all sentient things that pleasure predominates over pain. Only on this assumption are we entitled to declare that life is worth living—which is the assumption that lies at the root of all our morality, otherwise murder would be a duty, and Napoleon, whose criminal lust for slaughter consumed 8,000,000 human lives, would be the supreme saint of history.

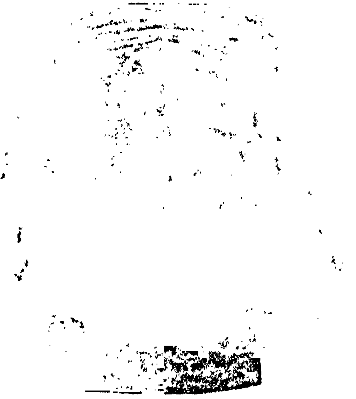
THE ART OF EGYPT

Prehistoric Realism. The Genius of the Ancient Egyptians. Their Temples and Monumental Triumphs. Their Conception of Ornamentation

By P. G. KONODY

THE valley of the Nile gave birth to the oldest civilisation of the world. The research of Professor Flinders Petrie and other scientists has proved beyond the possibility of doubt that the art of the early historic period of Egypt, such as it appears in the Pyramids and other monuments, dating from about 3,500 years before the beginning of the Christian era, was preceded by a still older and comparatively highly developed civilisation, which takes us back at least another 4,000 years, and had arrived at consummate artistry in the carving of hard stone and ivory, and even evolved a system of writing.

The Art Instinct in Personal Decoration. Presumably, like other primitive races, the prehistoric Egyptians, who were probably of Libyan origin, found the first field for the exercise of their art instinct in personal decoration; and from the earliest pictorial representations of human figures on pottery and on the walls of tombs, as well as from the primitive painted clay figures, it would appear that the men were in the habit of covering their body with red paint and women with yellow, a custom which, perhaps, was still in force in the early dynastic period. In addition to this, zigzag lines, animals, and symbolic marks were first painted and afterwards tattooed on the body, and a green line painted under the eye with powdered malachite. The palettes used for the purpose of powdering the colour, together with food-vessels, weapons, and all manner of implements, were buried with the dead, and enable us now to form a fairly accurate idea of the life, customs, and art of this remote period. The palettes in particular are carved into the semblance of animals, or have images in relief on the surface. Similar representations of animals are to be found carved on ivory combs and pins and shaped in pottery. In the painted decoration can be found boats, temples, mountains, trees, and human figures, in addition to animals; but there is a notable absence of purely ornamental design. The nearest approach to this is to be found in the perfectly symmetrical chip marks of the flint knives, which were fashioned with consummate skill and with a neat finish which was never approached by other primitive races.

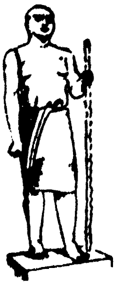


9. EGYPTIAN OFFICER OF 4th DYNASTY

The Realism of Early Egyptian Art. Religious belief and the cult of the dead were among the chief factors that led to artistic activity, and it is a point that has yet to be settled whether the earliest manifestation of Egyptian art, in sculpture and in drawing, were due to a belief in the magic power of such imagery or to the pure artistic instinct. The most remarkable point in connection with the art of the prehistoric Egyptian is its absolute realism, which is in striking contrast to the severely formal, hierarchic style of the "classic" or dynastic period. The prehistoric Egyptian was a student of nature, a searcher for truth; the dynastic artist a producer, as it were, of grand, majestic hieroglyphics which conveyed a firmly fixed mystic meaning, but had to comply with certain forms, and gave no scope to individual expression.

Between the realistic art of prehistoric Egypt and the hierarchic art of the Old Kingdom there is no period of transition; but the former, which was the art of the people, overlaps the latter, the art of the rulers. This has been one of the chief reasons for the theory that the classic art of Egypt, which in some of its phases shows a certain kinship with that of Chaldæa, came in the train of Asiatic conquerors who had crossed the Red Sea from Yemen to the land of Punt, and gradually flowed into the Upper and then the Lower Nile valley. The invasion was slow and gradual, and the conquerors absorbed much of the civilisation which owed its origin to the unique natural conditions of the Nile valley.

The Impressiveness of Egyptian Art. The genius of the dynastic Egyptian was entirely architectural and sculptural, not pictorial. Everything aims at monumental effect, impressiveness, weight of masses. The mighty pyramids erected over the tombs of the kings; the giant Sphinx, which has been the wonder of countless generations that have stood before it in awe and admiration, unable to solve its eternal mystery; the enormous temples of Karnak and Luxor; the colossal statues of the kings, seated in hierarchic dignity, the very personification of greatness and power—all these are artistic creations that have never been surpassed in grandeur and impressiveness, and were, no doubt, calculated to inspire the people



10. THE SHEIK EL BELED

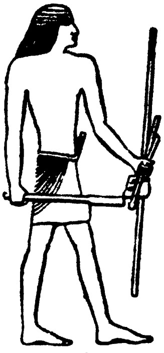
with the consciousness of the superhuman power of their divinities and kings and priests. The mystic element in nature has never found more fitting expression in art, and even at the present day ancient Egyptian motifs and ideas are employed whenever the mysteries are to be suggested.

At the very beginning of the dynastic age, wattle and mud were replaced as building material by brick and stone. Both were employed for the building of the Pyramids, which were erected in terraces, diminishing in size towards the top, the steps being filled in from the top downwards until the perfect pyramidical shape was achieved. Within each pyramid is a room, which is reached by a narrow passage and contains the sarcophagus of the king, and a little chapel destined for the cult of the dead.

The Sphinx and Pyramids. Of the grandeur of these Pyramids, and the energy entailed by their erection, some idea may be gathered from the fact that the Pyramid of Khufu, or Cheops, contains some 2,300,000 blocks of stone, each weighing on the average two and a half tons. The colossal Sphinx, the guardian of the three famous Pyramids of Gizeh, is hewn out of a rock embedded in the sand of the desert, which has gradually buried its lion-shaped body, so that only the neck and shoulders are visible. The conception of the Sphinx, with its weird power of mysterious suggestion, is unquestionably the greatest achievement of Egyptian art—nay, stands alone in the art of all times and countries.

12. CAUSEWAY AT THE SECOND PYRAMID

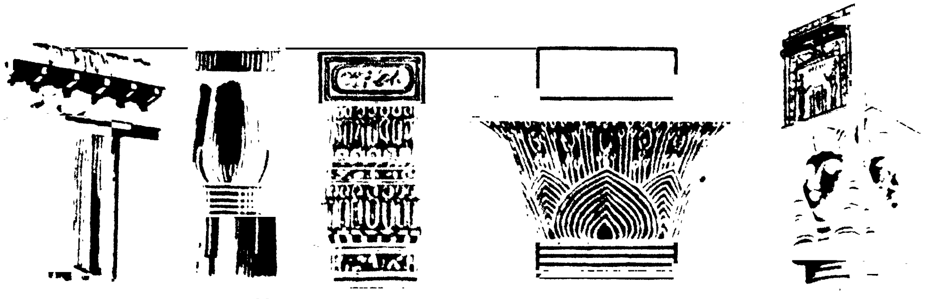
From the beginning of the Third Dynasty, about 3000 B.C., until the end of the Empire, about 1150 B.C., the rulers of Egypt were prodigious in their building activity, but the forms had become stereotyped at an early date; and what progress there is to be noted is only in the direction of greater technical perfection—in sculpture as well as in architecture. Thus the square, unadorned stone pillars, such as were used in the causeway leading to the second Pyramid at Gizeh [12], gradually took the shape of articulated columns. In the rock-tombs of Beni-Hassan, the progress can be clearly observed. First of all, the pillar is given eight facets, then sixteen, and each facet is hollowed out into a groove to accentuate the edges. The architrave is crowned by a cornice and a square slab introduced between the pillar and the architrave. A circular slab connects the pillar with the ground. We have here all the rudiments of the orders of architecture.



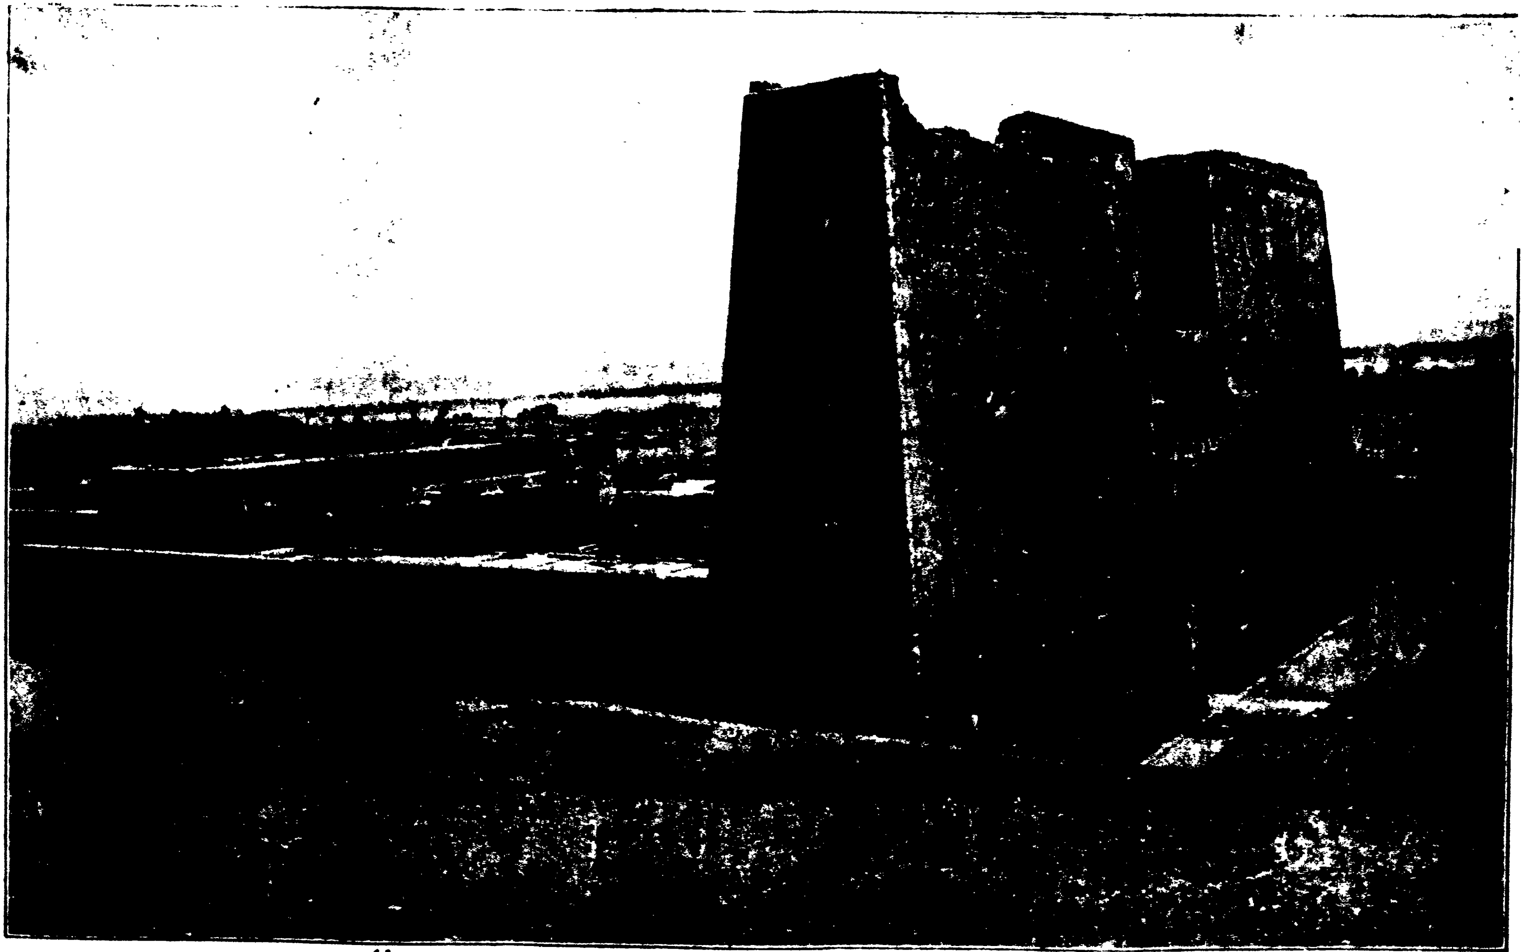
11. TYPICAL EGYPTIAN RELIEF FIGURE

The next form is a clear imitation of a plant form—of the lotus. The capital represents a closed flower with four leaves; the shaft, which tapers towards the top, is formed, as it were, of four stalks, which are tied together at the top by ribbons carved out of the stone, and marking the base of the capital. Later, at Karnak, where not only the walls but even the surface of the columns are covered with paintings and hieroglyphics, the lotus form is still further simplified and conventionalised, shaft and capital being perfectly compact and rounded off; but in other columns an important innovation is introduced in the form of a capital representing an opened lotus flower, in which may, perhaps, be found the first suggestion for the volutes of the Ionic capital [13].

The Egyptian Temples. The whole essence of Egyptian art—architectural, sculptural, and pictorial—is embodied in their temples, which were erected on extensive brick terraces raised high above the flat banks of the river, and enclosed within mighty walls sloping towards



13. DEVELOPMENT OF THE EGYPTIAN CAPITAL



14. ONE OF THE MOST IMPRESSIVE RUINS IN EGYPT: THE TEMPLE OF EDFOU

Zangaki

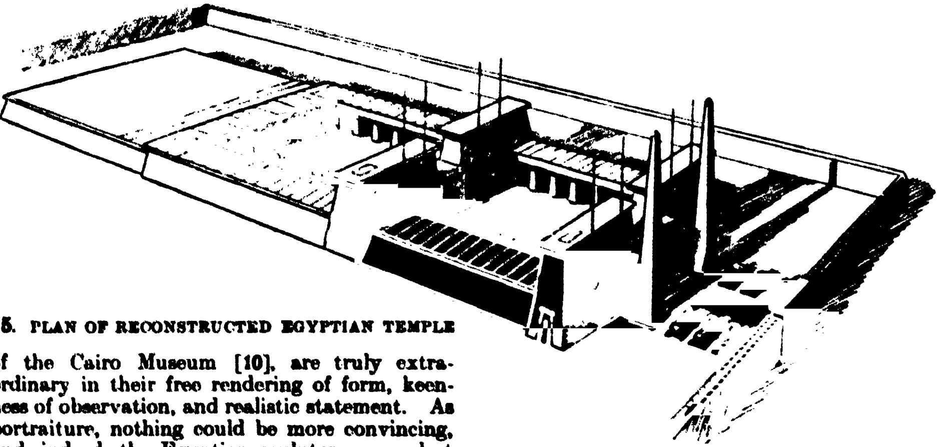
The two great pylons rise to a height of 112 feet. The court, between the pylons and the great hypostyle hall, is surrounded on three sides by a covered colonnade of 32 columns the top and crowned by a grooved, projecting cornice. The very enclosure has a solemn and mysterious effect, which is maintained and enhanced by every feature in the interior. *The pyramidal formation of the gently sloping walls, which is consistently carried through the entire temple buildings, not only gives stability but avoids the abrupt angle of a wall rising vertically from the ground, and produces a pleasing effect upon the eye.* In the building of country houses some modern architects, like Mr. Voysey, have followed the same principle, with the happy effect that their cottages are not ugly structures planted in the midst of a landscape to ruin it by their inappropriateness, but seem naturally to grow out of the soil.

From the gate on the river-side a symmetrically planted avenue of stone sphinxes, or rams [16], leads to the entrance-gate of the temple, which is flanked by two towering pylons, sloping and corniced like the outer wall [14]. Obelisks and seated royal statues flank the entrance-gate, which leads into an outer court enclosed by covered colonnades. Frequently the same arrangement of pylons and enclosed court is repeated before access is gained to the inner temple, which consists of a mighty stone-covered, pillared hall with a raised central nave, which is provided at both sides with openings for light like the clerestory walls of our churches, and the sanctum with numerous priestly apartments arranged around the mysterious gloomy "cella," the holy of holies, which held the image of the god. All the outer and inner walls, and even the columns and ceilings, are covered with pictorial symbolic representations in rich colours, which still further enhance the powerful impression of these buildings [15].

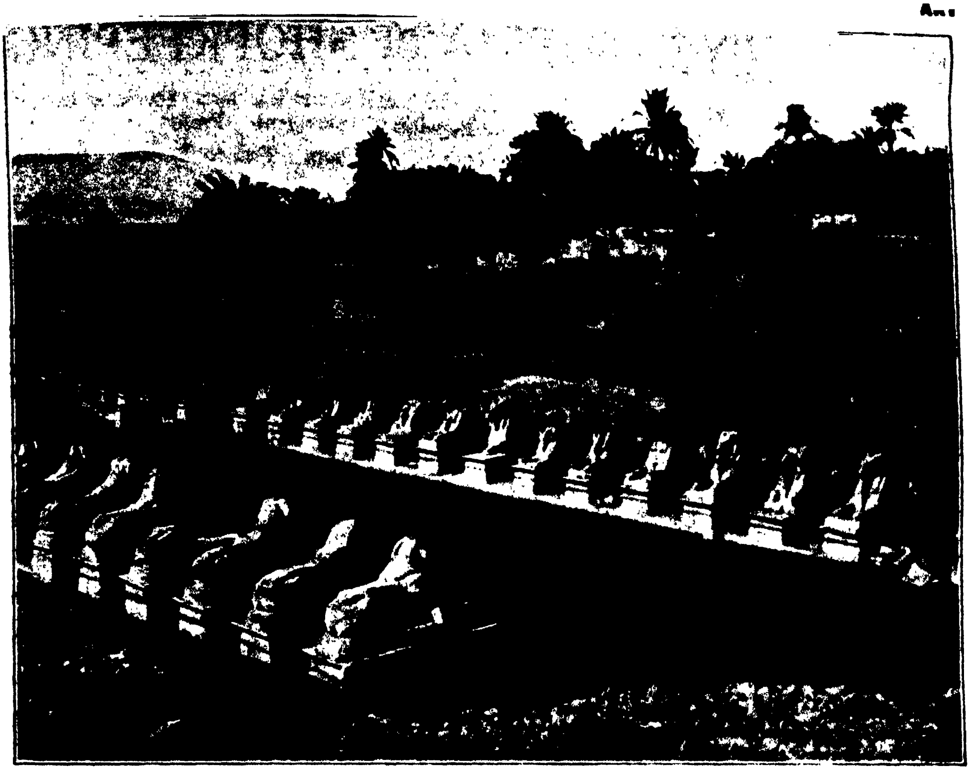
Early Egyptian Sculpture. The earliest examples of Egyptian sculpture, like the famous "Scribe" in the Louvre and the Sheik El Beled of the Cairo Museum [10], are truly extraordinary in their free rendering of form, keenness of observation, and realistic statement. As portraiture, nothing could be more convincing, and, indeed, the Egyptian sculptors never lost this gift of faithfully recording the features of the person represented, even when the early realism had been ousted by architectonic formulas—the individual by the typical. For well nigh 3,000 years they continued to work according to the rules established by tradition. Again and again they chiselled the seated figures of their rulers, with their legs and feet and arms and hands in perfect symmetry, all in one massive block, the expressionless face looking straight ahead [9]. And the same lack of invention and stiffness is to be observed in the standing and in the kneeling figures—everything is in dignified, stiff repose, without an attempt at movement or expression. The features are recorded with the dryness of a topographic map, as though the expression of human emotions were outside the range of art. During 3,000 years of constant artistic activity no Egyptian sculptor ever thought of raising one of the heels of a standing figure from the ground and letting the weight of the body rest on the other foot. The result is that the action of the muscles plays no part in Egyptian sculpture, and though the muscular forms are at times indicated, they lack all accent and expression; as in the features of the face, there is not a trace of passion and emotion and action, of all that is essentially human. Imposing dimensions have to replace spiritual significance; but there is something intensely awe-inspiring in these gigantic stone images, a suggestion of mysterious power in their grand, lapidary inflexibility.

Pictorial Art of Ancient Egypt. We have already stated that the genius of the ancient Egyptians was essentially architectural and sculpturesque; even their sculpture has an architectural, massive character. Their pictorial art never rose to any degree of independence. It was partly a development of the relief sculpture with which they loved to cover every available space on the walls and columns of buildings, partly an easily intelligible method of writing down their records of historical events and religious mysteries. Painting, in the true sense of the word, was unknown to ancient Egypt. Colour was only applied in flat masses to fill in the outlines of their relief pictures and drawings on papyrus. Even where the walls are not covered with relief decorations, the paintings are treated in the same manner.

The subject matter of these pictorial and relief representations is exceedingly varied, and not



15. PLAN OF RECONSTRUCTED EGYPTIAN TEMPLE



16. THE AVENUE OF SPHINXES AT KARNAK, ORIGINALLY A MILE LONG *Perkins*

Leading from the Temple of Luxor to the Temples of Karnak

only embraces the religion and daily life of Pharaonic Egypt, but forms a faithful chronicle of historical events. But here, again, everything is hidebound in convention. The king, for instance, must always considerably exceed all other figures in size. The attitudes are more varied than in the monumental sculpture, but have always to comply with certain rules. Thus face, legs, and feet are invariably drawn in profile, but the shoulders and torso full face [11]. Foreshortening and perspective were unknown to the Egyptians, and of composition, in the modern sense of the word, there is never a trace. The figures are placed side by side in long rows, or one above the other. Racial characteristics are well marked in features and costume, but there is no attempt at individual characterisation. In fact, the painting and drawing of the ancient Egyptians was a kind of hieroglyphic language that has little more in common with art than the use of pigments. If the stereotyped forms undergo certain changes in the course of the many centuries, these appear never due to individual initiative, but rather to a general fashion, which demanded, say, different proportions for the bodies. In looking at the ancient Egyptian monuments, reliefs, and wall paintings, one would no more think of the artists who produced them than one would inquire into the name of the compositor who happens to set the type for a modern book—and to a great extent the pictures on the walls of the temples and tombs were the books of the people of that remote period.

Ancient Relief Sculpture. The relief sculpture of the Egyptians had little in common with that of later civilisations. The figures do not project from the level surface of the wall, nor do they show much modelling of the forms. The outlines are merely cut into the stone, and then the background chiselled away to a certain depth, so that no part really projects from the wall. But the painting with bright colours lends the decorated wall the quality of rich embroidery or carpet hangings.

The ornamental motifs of the Egyptians were, in the prehistoric time, chiefly suggested by the patterns of basket-work, and later by the flora and fauna of the country. The lotus and papyrus plants and the winged beetle supplied conventional forms which were not only used with the happiest results by the dynastic craftsmen, but have survived even to the present day. Indeed, certain phases of the modern "art nouveau" movement can be traced back to distinct Egyptian influences. Altogether the art of no other country or period lends itself so well to the suggestion of the supernatural and mysterious; and from this point of view it is worthy of note that in the decoration of masonic temples Egyptian motifs are almost exclusively resorted to.

FISHING TACKLE DEALERS

Unlike certain other trades, the selling of fishing tackle is rather difficult to understand. There is such variety in a complete stock, the nature of which varies so in different districts, that very careful study indeed is necessary to understand exactly what to keep. For instance, we know of a shopkeeper who resolved to add fishing tackle to his business, and wrote to a wholesale firm, who in turn sent their traveller to see him. Thinking that the traveller would know all about the business, the retailer left the selection in his hands, and ordered something like £75 worth of fishing tackle. The goods arrived in due course, and were priced and put on the shelves, and the shopkeeper awaited customers. When the artful angler came to purchase, the merchant found that the articles he had to show were considered utterly useless for the district. Eventually he wrote to the wholesale firm asking them to take the stock, and offering to lose a certain amount on the goods.

Personal Touch. This shopkeeper went the wrong way about the business. In the first place he should have made the acquaintance of a few good anglers in the district and got from them the necessary information regarding the tackle to purchase, and if he had been very energetic he would have furnished himself with an outfit and gone to the streams himself in the company of a good angler. In this way he would have picked up the necessary knowledge of how to purchase, and the kinds of tackle required. No person can go into the fishing tackle trade properly unless he be an angler fishing the various streams and lakes himself. In this way he comes into contact with the angling fraternity, who purchase their requirements from him with full confidence. The writer started this business twelve years ago with little knowledge of it, but by careful study, and by taking every opportunity of getting to the water's edge with good anglers, he soon learnt the art and built up a good business. Later on the scope was extended, and a small workshop was erected with the necessary tools for the repair of broken rods, splicing, fitting new ferrules, rings, etc., and in time every branch was at command.

Capital and Stock. To start a fishing tackle business properly would require a capital of from £200 to £300; but to begin in a small way £75 to £100 would be sufficient, and it should be laid out very carefully, somewhat as follows:

Rods, greenheart, 3 piece, 11 and 12 ft., light fly, with bronzed winch fittings and butt cap, ranging in price from 7s. 6d. to 30s.
Rods, hickory butt, ash centre, and lancewood top, 11 and 12 ft., with brass winch fittings and butt cap, ranging from 3s. to 6s.
Rods, ash and lancewood top, for boys, 9 to 11 ft., from 6d. to 2s. 6d.
Reels, revolving plate, 2 to 3 in., ranging in price from 4s. 6d. to 7s. 6d.
Reels, bronzed crank, 2 to 3 in., ranging in price from 3s. to 4s. 6d.
Reels, brass crank, 2 to 2½ in., ranging in price from 2s. 6d. to 4s.
Reels, brass (American), 1½ to 2½ in., ranging in price from 6d. to 2s.
Rod fittings, brass butt caps, assorted sizes in brass and bronzed butt caps.
Rod fittings, brass and bronzed ferrules and counters, assorted sizes.
Rod fittings, winch fittings, brass and bronzed, assorted sizes.
Rod fittings, German silver, rings, keepers, hitchers.
Rod fittings, end or top rings and steel snake rings.
Lines, best waterproof silk, 20, 25, and 30 yd. boxes.
Lines, plaited hemp, 20, 25, 30 yd., on boards.
Lines, plaited hemp, 40 yd., on boards, for pike.
Lines, barked, for boys, 1d. to 4d.
Floats, cork, egg-shaped, assorted.
Nets, landing, assorted sizes.
Rings, folding, assorted sizes.
Handles, bamboo and ash, 4 ft. long.
Nets complete, with folding ring and handles, to sell at 3s. to 4s. 6d.
Gut cast lines, 3 yd. long, tapered, each 1 × 2 × 3 × 4 × 5.
Gut cast lines, 2 yd., heavy, for bait fishing.
Gut cast lines, 1 yd., heavy, for bait fishing.
Gut traces, 2-swivel, 1½ yd. long.
Gut traces, 3-swivel, 2 yd. long.
Traces, gimp, 2-swivel, 1½ yd. long.
Traces, steel, 2-swivel, 1½ yd. long.
Gut, in hanks of 100, undrawn, heavy, medium, and fine.
Gut, in hanks of 100, drawn, medium, and fine.
Hooks to gut and to gimp, assorted sizes.
Stewart tackle and Thomson tackle, assorted sizes.
Pike hooks, double wire, assorted sizes.
Hooks, loose, in 100 packets, assorted sizes.
In flies for streams the following are a good selection for most waters: Teal and red, teal and green, teal and yellow, woodcock and hare's ear, woodcock and red body, woodcock and green body, woodcock and yellow body, March brown (male and female), butcher, Greenwell's

Glory, pheasant back, cow dung, bustard, May fly, July dun, August dun, olive dun, blue dun, whirling dun, grouse and claret, black gnat, blae and hare's ear, blae and yellow.

Flies for lake fishing: Teal and red, yellow and green, butcher, silver doctor, nuen, Greenwell's Glory, woodcock and red, woodcock and green, woodcock and yellow, blae and black, grouse and claret, grouse and green, grouse and organe, Heckham Peckham Professor, pheasant and yellow, Alexandra, sand fly.

Baskets, fishing, white, No. 2, 3, 4, 5, 6.

Books, 6 in., with two pockets, to sell at 1s.. 1s. 6d., 2s., 2s. 6d.

Books, 7 in., with two pockets, leather cover, to sell at 3s. to 7s. 6d.

Minnows, artificial, silk phanborus, assorted sizes.

Minnows, Devon silver, assorted sizes.

Minnows, Devon gold, assorted sizes.

Minnows, Devon bronzed, assorted sizes.

Minnows, screw tail.

Spoon baits, silver back, copper inside, assorted sizes.

Spoon baits, silver back, red inside, assorted sizes.

Spoon baits, with feather on hooks.

Archer spinners, sizes—trout, salmon, pike.

Sinkers, split shot, 1d. boxes.

Swivels, steel, assorted sizes.

Swivels, brass, assorted sizes.

Straps, basket, 1s., 1s. 6d., 2s. retail.

Bags, waterproof, assorted, 3s. to 7s. 6d. retail.

Hooks, gimp, assorted sizes.

Leads, pear-shaped, 3 oz., 5 oz., ¼ lb., ½ lb., 1 lb.

Leads, mackerel, pear shape, 2 lb.

There are other articles in use in certain parts, but this forms a general stock.

Profits. It is necessary that at least 50 per cent. profit should be put on all classes of fishing tackle so as to allow for loss which is unavoidable through having to sell old stock at much less than cost price, and in certain cases having to destroy it altogether. It must be borne in mind that a fishing tackle dealer turns over his stock value not more than once a year.

Stockkeeping. There are various ways of shelving this stock, but the simplest is to get a number of empty collar-boxes, which can usually be procured from any hatter or draper, to cover the fronts with green paper, and to print thereon the names of the different articles contained. In this way the dealer can put his hands on the different articles without trouble, and also save money, because small parcels carelessly kept are very easily lost. One can put about £10 worth of gut casts into a small envelope, so that the advisability of boxes is apparent. A stock of fishing tackle takes up very little room, as most of the articles are very small. It is necessary to be very careful with the buying of all kinds of flies, gut, hooks, gut casts, and loose gut, so that there is a sufficiency for one season only, as any left over until another season may be treated as bad stock. All kinds of gut and flies lose their strength after a time, becoming liable to break, and to an angler there is nothing more annoying than after hooking a fish and playing it a few minutes to find it escape through the tackle giving way.

Sea Fishing. The tackle required for sea fishing is neither varied nor expensive, and requires very little knowledge in handling. £10 to £15 will go a long way in providing a good stock, which ought to be somewhat as follows:

Rods, ash, 2-joint, 9 to 12 ft., varying in price from 2s. to 5s.

Rods, bamboo, 3-joint, 6d. retail.

Rods, 3-joint, 1s. retail.

Lines, hemp, in hanks, 1d., 2d., 3d., 4d., 5d., 6d. retail.

Lines, hemp, on wood reels, mounted with hooks and leads, 6d. and 1s.

Hooks on common hair, assorted sizes.

Hooks on twisted hair, assorted sizes.

Hooks, tinned, in 100 packets, assorted sizes.

Spinners, mackerel, assorted sizes.

Sand eels.

Flies, sea, large, to retail at 1d. and 2d. each.

How to Spend the Money. The relative expenditure upon the various departments of the stock should approximate to the following proportions. We have assumed that £100 is being expended in merchandise, and that the district is one that offers fishing facilities in river, lake and sea:

Rods	£20	0	0
Reels	10	0	0
Lines	5	0	0
Nets	3	10	0
Fittings	3	10	0
Sundries, of which there are a great many	11	10	0
Flies, assorted	10	0	0
Gut casts and traces	10	0	0
Gut in hanks	2	0	0
Gut hooks, Stewart and Thomson tackle	2	0	0
Loose hooks	1	0	0
Minnows	3	10	0
Bags and baskets	2	0	0
Rods, sea	5	0	0
Lines, sea	3	0	0
Hooks and hair for sea fishing	1	10	0
Loose haddock hooks ..	1	0	0
Other baits, floats, leads, flies, etc.	5	10	0
	£100	0	0

Repairing Department. Directly, rod repairs do not pay, as a considerable time is taken up with small jobs which cannot be rushed; but when a gentleman breaks a top-piece or any other part of his rod, his first consideration is where to get it put right, and the dealer who can do this properly for him is rewarded by getting his orders for tackle. Not only so, but he feels so pleased at having got the job done so handy that he has to let all his angling friends know of it and where he had it done, and in this way new customers are secured.

The following is a list of tools required for the workshop and their cost:

1 6-ft. bench, with stop, 15s.

1 bench vice, 12s. 6d.

1 small drilling machine and set of twist drills, 30s.

1 3½-in. centre turning lathe, with set of tools, £5.

1 trying plane, 6s. 6d.
1 jack plane, 5s.
1 hand plane, 3s. 6d.
1 small Stanley iron plane, 2s. 6d.
1 spokeshave, 1s.
An assortment of files from 4 in. to 8 in., say, 2s. 6d.
A few steel scrapers, 2 in. to 4 in., 1s.
1 small gluepot, 1s. 6d. to 2s. 6d.
A few reels of tying silk—red, green, yellow.
A quantity of best coach oak varnish, glasspaper (assorted), mahogany, walnut, and rosewood stains.

FISHMONGERS

The prime essential for the fishmonger is rude health. Without a constitution capable of withstanding the coldest wintry blast, there can be little chance for the ordinary man or woman who intends to make a livelihood at the business, for the necessities of the trade make exposure to the weather in an open shop imperative at all seasons of the year. And the commodities that are handled have to be cool—if not cold—in all seasons, so that the cleaning of fish in the depth of winter, with the thermometer registering 15° below zero, requires a hardihood that is only acquired by fundamental soundness of constitution acclimatised to varying meteorological conditions by years of experience. The business of a fishmonger is often allied to that of a poulterer and game-dealer; but for the present the vending of the various kinds of fish only will be considered, and game will be dealt with later. Some grocers, and most of the larger departmental stores run fish departments, and in some localities these may be formidable rivals to the young man who essays to secure his living by fishmongery pure and simple. But granted good health, cleanliness, experience in buying and selling, and the attributes of politeness and attention to business—without which no great success can be attained—the trade is one that will repay the exertions of a careful dealer.

Training. This is distinctly one of the businesses in which an untrained person is most likely to come to grief. Occasionally, gentlemen's servants, who have acquired, as they imagine, a more or less intimate knowledge of buying in fairly large quantities for their master's tables, think they know all that is needed to embark in a retail business. There can be no greater mistake, for buying is only one of the many things necessary; cutting up and selling are totally different, more particularly when the cutting and selling must be done in such a careful manner as to secure a profit sufficient to pay the rent of a shop, the taxes, the help required, the keep of a man—with probably a wife and family to boot—and the saving of a little money for the proverbial rainy day. So the butler who invests his savings in a fishmongery business more often than not invites financial disaster. An apprenticeship, and a full experience in the business, are absolute necessities for success. The best way to learn the trade is from the "basket," so to speak, upwards. Two or three years with a retailer having a brisk family business, and a few more with a good wholesaler in the market, give the necessary insight into the intricacies of the calling, and a knowledge of goods that are as perishable as can well be conceived, and must therefore be handled with the skill and forethought only acquired by intimate knowledge.

Capital and Credit. With a sum of from £50 to £80 in hand, a man well equipped with the other essentials mentioned may make a creditable start. Of course, he would not expect, with such an amount, to rush into fortune in a few years, nor would he look for his shop in a high-class suburb or a West End residential neighbourhood, where monthly, three-monthly, or six-monthly statements of account only would be entertained by his customers. He would select a good middle-class suburb, or the busy thoroughfare of a working-class town, and the bulk of his sales would have to be for hard cash, with perhaps a few weekly bookings. And at the outset he would have to see to it that his weekly accounts did not extend to a fortnight or to three weeks, as accounts have an insidious way of doing if allowed. He must not forget that with so small a capital quick returns are essential, for the wholesaler in the markets, or at the coast, will not give credit for any length of time until the new starter's financial solidarity is assured. Let the limit of credit to the customer, even if his bona-fides be well established, be restricted, therefore, to one week.

The Shop and its Requisites. If the shop selected be not too large and the rent not too high, it will pay the man with an eye to the future to fit it up well. A suitable shop at an annual rental of from £40 to £50 may be secured in a medium-class neighbourhood. No window is required, for the hardy fish-seller must display his wares on cold marble slabs, and brave the elements. The marbled window-ledge and marble shelves are preferably supplemented by a floor of concrete, or tiled or tessellated if the money be sufficient. An ice-box is needed for summer storage. Cleanliness and coolness are two requisites, and nothing looks cleaner or cooler than well kept marble. A slate fish-block, over which a water-tap is arranged, and which is set in a tank, is needed for cutting up and cleaning the fish. This block would probably cost about £5. An arrangement of zinc and wood is often substituted at first, the initial outlay for this being less. Wooden shelving round the shop is also useful, and pails, knives, skewers, weights and scales, and a plentiful supply of paper are necessary. If carefully gone about a sum of £25 will cover all the fittings, even those indicated as ideal, but the beginner will probably not be too lavish with marble slabs and tessellated pavements until he has time to gauge the opportunities for development in the neighbourhood.

Laying in Stock. The fish-vendor must either attend the market daily, if he have one within reach, or arrange with the wholesalers at the coast towns (Grimsby, Yarmouth, Hull, Lowestoft, Plymouth, Peterhead, etc.), for regular daily supplies to be sent direct. Thus, if he happen to pitch his camp in a metropolitan suburb, he will go to

Billingsgate in the early morning with £10 or so in his pocket, and (supposing he start in March) he will probably make a selection consisting of two-stone quantities each of plaice, haddock, hake, codfish, whiting, mackerel, herrings, bloaters, kippers and smoked haddocks. At that season of the year turbot, soles, and salmon are scarce and rather dear, so probably six or seven-pound quantities of these would be found sufficient. Shrimps and oysters are seasonable then, and 28-lb. stocks of these would probably have to be ordered. But it will be understood that the experienced man who has fairly gauged the potentialities of his neighbourhood and who knows the condition of the market will buy the fish that are dear—or are less likely to sell—in smaller quantities, and the cheaper and quicker selling varieties in greater abundance. Besides these, one cwt. of ice must be stocked; this is obtained from the ice companies and does not cost much.

Fish in Season. The following table indicates approximately the months of the year in which various kinds of fish are considered "in season" in this country:

Fish.	In season
Barbel	January, February, March, Oct., Dec.
Brill	Each month *except* May, June, July, and September.
Carp	Each month *except* October.
Cod	Each month *except* April, May, June, and July.
Chub	May and August.
Cockles	April.
Crabs	Each month *except* June, July, and September.
Crayfish	Each month *except* April, September, October, November, and Dec.
Dace	January, February, March, and Dec.
Dory	April, May, July, and August.
Eels	Each month *except* April, May, June, and July.
Flounders	Each month *except* May, June, Nov., and December.
Grigs	October.
Gudgeon	October, November, and December.
Haddocks	Each month *except* April, May, June, and August.
Herrings	Each month *except* April and Nov.
Lampreys	January, February, and March.
Ling	April.
Lobster	Each month *except* November.
Mackerel	May, June, and July.
Mullet (red and grey)	April, May, June, July, August, Sept., October.
Mussels	January, February, March, and April.
Oysters	Each month *except* May, June, July, and August.
Perch	January, February, March, April, and December.
Pike	Each month *except* April, May, Sept., and October
Plaice	January, February, March, July, September, and October.
Prawns	Each month *except* Nov. and Dec.
Salmon	April, May, June, July, and August.
Shad	April and May.
Shrimps	Each month *except* May, June, Sept., October, and November.
Skate	Each month *except* May, June, July, and November.
Smelts	January, Feb., March, April, and May.
Soles	All the year round.
Sprats	January, Feb , March, April, and Dec.
Sturgeon	Jan., Feb., March, April, July, and Aug.
Tench	Each month *except* May and August.
Thornback	Each month *except* May, June, Sept., October, and November.
Trout	May, June, and August.
Turbot	Each month *except* July.
Whiting	Each month *except* May, June, July, and August.

Sources of Supply. Nowadays, all the markets of the country are brought within easy reach of the dealer by the facilities provided by cold storage and by rapid transit from the fishing ports by means of the extensive system of coast and inland railways. Fisheries fluctuate yearly—for example, the herring fisheries in Scotland—but ice-packing and special fish-trains guarantee the freshest of fish always in the metropolis. Herrings are obtained from ports along the whole of the east coast of England, from the English Channel, and to a smaller extent from the Welsh coast and the west side of England. The season for drift-fishery begins on the Northumberland coast in the latter part of July, getting later as one gets southward; for Yarmouth and Lowestoft, October and November are the months; in the Channel, November and December; and in the extreme west, the catch is best in the early part of the year. Thousands of tons of mackerel caught round the Cornish coast are landed at western ports (particularly Plymouth and Penzance), yearly, during the season, February to June. Pilchard comes from the coast of Cornwall and the south coast of Devon, from July to September. Sprats are caught in the Solent, in the estuary of the Thames, and in the Wash (between the Norfolk and Lincolnshire coasts), between November and February. Whitebait are caught in the Thames, while cod, haddock, whiting, coalfish, pollack, bream, and conger are regularly caught round the English coast. The cod fisheries in the North Sea are perhaps the most important.

Off the coast of Scotland the principal catches are herrings, cod, haddock, and ling. The seasons are April and May for the north and west coast hauls, and July to September for the east coast. The principal ports are Wick, Peterhead, and Fraserburgh. Sprats, or garvies, are caught in the Beauly Firth and in the Firth of Forth; while cod, haddock, ling, and saithe (or coalfish), are general round the coast. Cod and saithe are also obtained from the Shetlands and from the Faroe Islands and Iceland. Haddocks are mostly sent from Newhaven and Eyemouth, while the famed "Finnan haddies" (smoked) come from Findon, between Stonehaven and Aberdeen.

Dublin is the headquarters of the deep-sea trawlers round the Irish coast, the principal trawling grounds being between Dublin Bay, Dundrum Bay, and the Isle of Man. The last named spot is favourite ground for soles, and the season is March to July. In January supplies also come from Saltee, near Waterford. Herrings and mackerel are the two most important Irish fishing industries, Howth and Ardglas (June to October) being, the headquarters for herrings, while Kinsdale (March to June) supplies the mackerel.

The demand for crabs and lobsters has increased so much in recent years that the supplies round the coasts of Britain have been insufficient and a large quantity is imported from Norway. The English markets are usually supplied from Cornwall and the south coast of England, the Orkneys and the Hebrides in Scotland, and the west coast of Ireland. Shrimps and prawns are obtained in the estuary of the Thames, Pegwell Bay, near Ramsgate, and Morecambe Bay being the headquarters of the shrimpers. The bulk of the English supplies of oysters are obtained from the beds of private companies—the Whitstable Company being the most ancient. Mussels and whelks come usually from Grimsby. Periwinkles are mainly sent to the London market from the Western Islands of Scotland, from the Orkneys and Shetlands, and from part of the Irish coast.

Prices and Profit. The retail prices to be charged will depend, of course, upon the scarcity or plentifulness of the catch. A few approximate London retail prices would be: cod (whole), 6d. to 8d. per lb., head and shoulders, 6d. to 8d. per lb., middle cut, 1s. per lb., tail, 9d. to 11d. per lb.; haddocks, 6d. to 7d. per lb.; mackerel, 6d. to 8d. each; brill (whole), 10d. to 1s. per lb., cut, 1s. 1d. to 1s. 3d. per lb.; herrings, 1s. to 1s. 4d. per doz.; red mullet, 6d. to 1s. each; plaice, 6d. to 9d. per lb.; soles (slip), 1s. 6d. per lb.; medium, 2s. per lb., lemon, 1s. per lb.; whiting, 5d. to 6d. each; halibut, 1s. 3d. to 1s. 6d. per lb.; flounders, 2s. 4d. to 2s. 6d. per doz.; live eels, 1s. 6d. per lb. The foregoing are all fresh fish; for dried fish, such as sprats, the price would be 1d. to 2d. per bundle; haddocks 7d. to 9d. each; kippers, 1s. 2d. to 1s. 4d. per doz. Shell-fish such as lobsters would sell at about 1s. 6d. each; prawns (large), 1s. per doz., small, 1s. 3d. per doz.; shrimps (picked), 1s. 6d. per pint, brown, 6d. per pint. Native oysters should sell at about 3s. per doz., seconds at 1s. 9d. per doz., and foreign varieties at from 1s. 3d. to 1s. 6d. per doz. The cost price, as before intimated, will vary according to the season and the catch; but it is absolutely necessary that an average profit of from 30 to 35 per cent. on the general turnover should be obtained to make the business go. On herrings, for instance, a direct profit of perhaps 100 per cent. may be on occasion looked for; but on other kinds of fish a much smaller profit is securable and the average should come out not less than the rate stated. Assistance will be required in the shape of a lad to clean up and take out orders, who will have to be paid from 5s. to 7s. per week. As the business progresses it may be necessary to get an assistant, at about 30s. per week, who will canvass for orders and attend to the customers. With good references the young fishmonger will find little difficulty in arranging for monthly credits from the wholesalers in the market or from the fish merchants, if he obtain goods direct from the fishing ports.

FLORISTS

A florist, according to the dictionaries, is "one who cultivates flowers," but in the present article we apply the word, in the sense usually accepted by denizens of towns, to a shopkeeper who sells flowers and plants. In the country, a few florists may cultivate the flowers they sell, but the florist of the big towns buys his flowers at Covent Garden if he is a Londoner, at the flower markets of the various big centres in the country, or has them sent to him daily by large cultivators in various parts of the kingdom. Among the larger growers there is a differentiation in special flowers or varieties. One man is a specialist in chrysanthemums, another in roses, a third in lilies, and so on; and while probably the bulk of the crop of each of these growers may, in England, be sent to Covent Garden, or, in Scotland, to Edinburgh and Glasgow, arrangements are made by country florists for direct supplies.

Learning the Business. The man or woman who sets out seriously to make flower-selling his or her life-work must, therefore, know not only where and how to buy, but how to sell, how to make up, and how to blend. The art of bouquet-making is one in which a fine sense of colour-harmony is a prerequisite. The artistic sense is more or less a necessity to the successful vendor of flowers, for the difference between a combination of floral emblems which demonstrates a distinction and taste in the manipulator and the hastily arranged, clumsily put together bunch is the difference between financial success and pecuniary disaster. Then the preparing of wreaths is an important factor of the business, particularly from a financial point of view, and if this is not properly learnt a significant part of the florist's gain has been forfeited. There are side-lines to the business, such as jobbing gardening—if we may coin an expression—of which the embryo florist should have an insight before starting in business, for jobbing lends itself to considerable development if carefully attended to. The experience necessary for all these things is better gained in a good florist's in a large provincial town rather than in the gardens of a nurseryman or in a purely country business.

Finance and Locality. The capital required to start is not large. Indeed, "a shilling and a basket" is said by facetious members of the trade to be all that is necessary. But we will endeavour to ignore the ubiquitous "flower-girl" of the metropolis who works on the humble shilling system, and assume that our young florist aspires to the dignity of a shop. He (for convenience we will take the male person as typical) has, let us say, not less than £50 to £60 in hand, and he selects a shop in a fairly good-class neighbourhood, the busier the better. It should be remembered that a poor neighbourhood is out of the question, for poor people cannot afford to spend money on flowers, however much they would like to. A small shop, such as would be necessary for a start, would cost in a metropolitan suburb probably from £50 to £70 rent per annum. In the provinces it would be less. But the selection of shop, with probably living premises attached, should be carefully regulated by the purse and the prospects.

Preparing for Stock. The cost of fittings would not be great. A few wooden shelves, a counter, a glass mirror, one or two glass shelves for the window, gas fittings, two dozen earthenware vases of various sizes for cut flowers, several brass ring or wire ring fixtures for holding pot plants, are all that is required, and would not cost more than £15 all told. The flowers themselves are fine display, and cover up artistically any architectural defects. If the young florist is not fortunate enough to have previously acquired a conjugal partner, he may find it necessary to have a lady assistant (at 10s. to 15s. per week), and in any case, even if he is able to work the business at first single handed, he will need an errand boy (5s. to 7s. per week) to clean windows, sweep up generally, and to take out the orders. March is a good season of the year to make a start, for then one gets a good selection both of cut flowers and plants.

An Opening Order. The shop ready fitted, and the opening day fixed upon, the young florist betakes himself in the early morning (if he is in a London suburb) to Covent Garden. There he would make a selection something on the following lines.

CUT FLOWERS.

Flowers	Quantity required	Cost per dozen blooms or per dozen bunches of 12 blooms.	Amount expended
Arum lilies	½ dozen blooms	4s.	2s.
Lilium longiflorum ..	½	4s.	2s.
Lily of the valley ..	½ .. bunches	8s. to 12s.	(say) 5s.
Daffodils	1	3s. 6d.	3s. 6d.
Violets	2	1s. 6d.	3s.
Roses (foreign) ..	1	6d.	6d.
Roses (English) ..	½	3s. 6d.	1s. 9d.
Azaleas ..	½	2s. 6d.	1s. 3d.
Tulips ..	½	1s.	6d.
Snowdrops ..	½	1s. 6d.	9d.
Hyacinths ..	½	3s.	1s. 6d.
Stock ..	½	3s.	1s. 6d.
Carnations (foreign) ..	3	9d.	2s. 3d.
Carnations (English)	1	3s.	3s.
Mimosa ..	1	1s.	1s.
Asparagus ..	1	6d.	6d.
Freezia ..	½	3s.	1s. 6d.
Ferns (various) ..	2	(aver.) 9d.	1s. 6d.
Ivy leaves ..	3 bunches	2d. per bunch	6d.
Berberis	2 ..	3d.	6d.
		Total amount expended ..	£1 14s. 0d.

PLANTS IN POTS.

Plant	Number of pots	Cost.
Palms (large)	1 dozen	30s.
.. (small)	2 ..	3s.
Ferns (large)	1 ..	12s.
.. (small)	2 ..	8s.
Tulips	½ ..	3s.
Heaths	½ ..	3s. 9d.
Solanum	½ ..	4s.
Genista	½ ..	4s.
Cyclamen	½ ..	4s. 6d.
Miscellaneous	1 ..	4s.
Total amount expended ..		£3 16s. 3d.

It will of course be understood that these prices represent fair average net prices at Covent Garden. All florists cannot buy at Covent Garden, and the prices of flowers vary with the season, so that the florist must exercise his judgment and regard these as merely exemplary of the range of an opening stock. Besides these flowers and plants, another £3 would be expended on wire frames (for wreaths, etc.), flower baskets and so forth. Buying must be done every second day at least, and as the business grows, attendance at the market every morning, or daily supplies sent to the shop, will be the rule.

Credit, Prices, and Business Promoters. In a business such as we have indicated the selling must be run for strict cash. The small capitalist cannot afford to give his customers credit, particularly in a new business, and when he has almost invariably to pay cash for his daily supplies. The stock of cut flowers must of necessity be turned over daily, as they are so perishable. This gives the beginner a certain amount of cash always in hand, and to cover loss from waste he must make a profit of 100 per cent. at least on cut flowers. That is to say, a bunch that cost him sixpence must be sold at not less than 1s. On plants a profit of from 25 per cent. to 50 per cent. on the turnover should suffice, as pot plants will keep. The best paying part of the business is, however, in the making of funereal wreaths, and care should be taken to develop this part of the business on every conceivable opportunity. Bouquets for weddings are also productive of much profit if tastefully and carefully made up, and in some neighbourhoods quite a large trade in "buttonholes" may be done. After paying all expenses an average profit of about 15 per cent. may be fairly looked for on the total sales. Many florists make the seed trade an important adjunct of their business, and provided the neighbourhood is a good-class suburban one with no large seedsman in the district, this traffic in seeds is not to be despised. Most suburban householders are proud of their gardens and their idiosyncrasies should be catered for. It is advisable (from a pecuniary point of view, if from no other) to pack seeds in one's own packets from seeds bought in bulk, for the put-up seeds bear a comparatively small profit. An advertisement running in the local paper is an aider and abettor of business to the beginner, and the bright shop with fresh stock always on view and attentive proprietor and assistants all combine to assure the success of the florist who begins even in a small way.

FRUITERERS

Within the past fifteen years the fruit trade in Great Britain has developed enormously. This is largely due to improved methods of cold storage, which has brought a plentiful supply, and, therefore, cheap fruit, within the reach of the million. The consequence of the demand has been naturally a rapid increase in the number of dealers in fruit. But the consumption of fruit is still growing, and to an energetic man or woman, with a more or less extensive knowledge of the trade, the retail business offers a fine field for activity. It must not be forgotten that there is much annoying opposition to the regular shopkeeper in the fruit trade from costers. These pushful vendors of fruit are thorns in the flesh of the fruiterer in business with a shop rent to pay. For the coster makes a practice of attending the wholesale markets, such as Covent Garden, buying up at a cheap price what is left after the regular auctions are over, and selling cheaply in the streets from his barrow or stall, or going from door to door in suburban neighbourhoods and selling for what he can get. It is a form of competition which the regularly-established shopkeeper finds it very hard to compete against, and it is even more irritating than the opposition of the neighbouring grocer, who makes fresh and dried fruits one of his side lines.

Preliminaries. We will assume, however, that a young man, who has a fairly accurate knowledge of buying and selling fresh fruit, is not daunted by fear of costers or aught else, and has determined to start on his own account. First of all he must have saved or acquired a capital of £60 to £100, and competent fruiterers state that, especially for a young man, a wife is an absolute essential. The advantages of a working matrimonial partner, with an equal interest in the success of the young concern, are obvious. The neighbourhood selected for the new start would be either a prosperous suburb or a small open (windowless) shop in the busy streets of a large town. The rent required for a small single-window shop in a middle-class London suburb, for instance, would be £30 or £40, rates and taxes making it up to £50 to £60. The beginner will best judge for himself whether a window with or without glass is most suitable for his trade and his neighbourhood, but he should see that he has the right to at least a few feet of forecourt in front of his window or beside his door to display some of his goods direct to his customers without the intervention of glass. The fruit-buying public nowadays exhibit a liking for seeing the fruit at close quarters, and a good deal of fruit retailing is done on the pavement in front of the shop.

Shop Fittings. The fittings required are by no means either ornate or elaborate, and £15 to £20 will cover all requirements in that line. Some wooden shelving round the shop, a quantity of bins, a few baskets and boxes for display purposes in the window and on the shelves, are necessary. Trestles for outside display are often employed even where there is an actual glass window, and the bottom of the window should be sloped and neatly fitted with attractive baskets, trays, and boxes for displaying the goods. A few glass shelves suspended from the window ceiling for holding special lines may be used, and one or two sets of scales with brass pans are necessary. The price of a set of scales and weights to weigh up to 7 lb. would be not more than 15s. A few baskets for sending out orders may be required, but it is assumed that the business done will be at first for cash almost exclusively, and that, with a few exceptions, perhaps, the customers will carry away the goods for which they have paid. Paper bags with names and addresses printed on are of course necessary, but an expenditure of £1 in that direction will go a long way. Small baskets cost from about 1s. 3d. to 1s. 6d. each; while larger sizes cost 2s. to 3s. 6d. In suburban neighbourhoods weekly credit is often given to customers, and when this is decided upon, two or three dozen small pass-books (costing 4d. or 6d. each) are necessary to keep tally with the weekly creditors. A boy to take out orders and clean up generally is a necessity; he will cost anything from 5s. to 10s. a week.

Fruits in their Season. The stock of a fruiterer, pure and simple—as apart from a greengrocer—exhibits considerable variation. It would be idle to attempt to tell a man what to buy and when. That must be learned by experience, and no amount of writing will enable a man to gauge accurately what to stock for his particular neighbourhood and when to buy. Everything depends on the season of the year, the state of the fruit crop, and the demands of the neighbourhood. We have endeavoured in the table on next page to give an approximate indication of the principal fruits which a beginner such as we have described would stock, the country or port from whence the fruits come, the manner in which they are received in wholesale quantities, and the season of the year at which they arrive in this country or are "in season" for eating or cooking purposes. Besides the items mentioned there are a number of dried fruits, such as prunes, raisins, currants, etc., and nuts (hazel, Barcelonas, Brazils, walnuts, etc.), that may or may not be kept at first, but which would probably be added with the development of business.

Buying. A decision which has recently been arrived at by the members of the London and Provincial Fruit Buyers' Association may have some effect on the purchasing powers of small buyers in future. The large buyers complained that the small buyers could purchase small quantities at Covent Garden and at large provincial markets on the same terms as the largest buyers, and a schedule was adopted which substantially increased the minimum quantities to be permitted to be sold by first-hand brokers. But the beginner will find little difficulty in buying correctly, provided he keeps a keen eye on things and attends the market regularly every morning, or every second or third morning, as need be. To lay in an opening stock our London suburban fruiterer would therefore go to Covent Garden early one morning and make his selection. The season of the year primarily determines the fruits he would buy, but we will suppose that he begins in January. He would select one barrel (about 120 lb.) of apples, which would cost him 21s. These would retail at perhaps 3d. per lb., so he would require also a good dessert apple (Newtown Pippin or whatever his fancy might be) to sell at 5d. to 6d. per lb., and of these a case of 40 lb. would cost him about 16s. These cases are always the same size, but the sizes of the apples often vary.

THE SOURCES, PACKAGES, AND SEASONS OF FRUITS

Fruit.	Sources.	Packages.	Season.
Almonds (sweet)	Malaga (Jordan)	Bags of about 106 to 108 lb.	December to March
,, ,,	Barbary		September to March
,, ,,	Valencia		December to February
,, ,,	Sicily		,,
Apples	Australia	Barrels of about 120 lb. and boxes of 40 lb.	May to August
,,	Canada (Ontario)	Barrels of about 144 lb.	November to March
,,	Canada (Nova Scotia)	Barrels of about 120 lb.	,,
,,	California	Cases of about 50 lb.	November to February
,,	England	Baskets of 28 lb. and 56 lb.	August to November
Apricots	England	Boxes of 12 to 60	May (green), June, July
,,	France	,, 12 to 25 and cases of about 96	June to August
,,	Cape Colony	,, 24 to 36	,,
Bananas	Canary Isles	Bunches of various sizes, loose and in crates of 1 and 2 bunches	All the year round
,,	Ceylon		
,,	Jamaica		
Blackberries	England	Baskets of from 6lb. to 28 lb.	September
Cherries	England	Baskets of 12 lb. to 28 lb.	April (forced), May, June
,,	France	Boxes of 2 lb. to 5 lb. and baskets of 9 lb., 10 lb., 18 lb. and 20 lb.	April to August
Chestnuts	England	Bags of 80 lb. and 120 lb.	November to January
,,	France		,,
,,	Italy		
Coconuts	Ceylon	Loose or in bags of 50 lb. to 100 lb.	June to November
,,	India		,,
,,	Africa		
,,	South America		
Currants (red and black)	England	Baskets of 5 lb., 12 lb. and 28 lb.	June to August
,, (black)	France	Baskets of 6 lb. to 8 lb. and 20 lb. to 24 lb.	June, July
Dates	Fez	Boxes of 80 lb.	October to February
,,	Tunis	Cases of 50 boxes of 1 lb. each	August to January
Figs	Smyrna	Boxes of 2 lb. to 5 lb.	,,
,,	Malaga		,,
,,	Valencia		January to October
Gooseberries	England	Baskets 6 lb. to 28 lb. and special varieties in 1 lb. punnets	May to August
,,	France	Baskets of 12 lb. to 15 lb.	May to August
Grapes	Cape Colony	Boxes of about 10 lb.	February and March
,,	Lisbon	Cases and barrels of 50 lb. to 55 lb.	August to November
,,	Malaga		
,,	Denia	Boxes of about 12 lb. and barrels of 26 lb.	August
,,	England	Baskets of 8 lb. or 10 lb.	
Lemons	Australia	Cases of 200 to 360	September and November
,,	Messina	Cases of 200, 300, and 360	November to August
,,	Naples		March to October
,,	Palermo		November to August
Melons	England	Baskets and boxes of 2 to 6, crates of 4 to 24, baskets of 12 to 18, cases of 24, 36, and 48	March to October
,,	France		,,
,,	Italy		,,
,,	Spain		,,
Nuts (Hazel)	England	Bags (about 128 lb.)	December to March
Oranges	Almeria	Cases. Finest qualities packed separately, wrapped in tissue paper in fancy boxes. Usually three sizes of cases containing 420, 714, and 1064 oranges respectively	November
,,	Australia		July to September
,,	Brazil		August and September
,,	Denia		November to July
,,	Florida		September and October
,,	Jaffa		October to February
,,	Messina		,,
,,	Malta		December to March
,,	Murcia		July and August
,,	Naples		May to August
,,	Palermo		October to February
,,	Seville		January to March
,,	Valencia		November to July
Peaches	England	Boxes of 12 to 36	June to September
,,	France	,, 12 to 15 and baskets of 14 lb.	July to December
,,	California	,, about 48	,,
Pears	England	Boxes (best packed in husks, each fruit in separate paper)	September to November
,,	Canada	Barrels of 160 lb.	,,
,,	California	Boxes of about 60 lb. to 80 lb.	,,
,,	South Africa	Cases of 20 to 50	,,
Pineapples	South America	Cases of 12	June to February
,,	West Indies	Cases of 6 to 12	,,
,,	Ceylon		,,
Plums	California	Cases of 28 lb to 30 lb.	September to March
,,	France	Baskets of about 20 lb.	,,
,,	England	,, 12 lb. to 28 lb.	,,
Raspberries	England	Baskets of 1 lb. to 12 lb.	June to August
Rhubarb	England	Bundles (loose)	April to July
Strawberries	England and Scotland	Punnets of 1 lb. to 12 lb.	May to July
,,	France	Baskets of 5 lb.	,,
Tomatoes	England and Scotland	Baskets of 6 lb. to 12 lb.	All the year round (under glass)
,,	Channel Isles	,, 12 lb.	June to August
,,	Canary Isles	Boxes of 12 lb. to 16 lb.	December to February
,,	Valencia	,, 7 lb. to 9 lb.	July
,,	Lisbon	Cases of about 40 lb.	August
,,	France	Crates of 24 lb.	

Then a bushel (40 to 43 lb.) of English cooking apples (Wellingtons, etc.) to sell at 4d. per lb. would absorb another 11s. Passing on to the orange section he would buy one case (containing 714 oranges) to retail at 6d. per dozen, and another case (of 420) to retail at 9d. per dozen; the larger case costing 15s., and the smaller 12s. to 12s. 6d. Then half a dozen boxes of Tangerines (costing 3s. to 4s.) might be secured to retail at 6d. per dozen. Bananas are nowadays an important item. He would select a "stalk" costing 8s. or 9s. Such a stalk would have in it anything from 12 to 17 dozen bananas, and the retail price would be 1s. per dozen. A 36 lb. barrel of green Almerian grapes (selling price 4d. to 6d. per lb.) would cost 10s., while a basket (8 to 10 lb.) of good black grapes (English or other) would run to 1s. 6d. per lb.—the usual retail price being 2s. Stewing pears would be required at this season, and would be priced at about 2s. per dozen—retail 4d. per lb. Lemons might be bought at 3s. per 100 and retailed at 1d. each. Twenty-four pounds of tomatoes, English and foreign, would mean another half-sovereign, at least, and small quantities of dates, figs, pineapples would pretty well exhaust the seasonable staples. But there are things like chestnuts, Barcelona nuts, Brazils, walnuts, and so forth, that the experienced man would find it necessary to order, and £2 or £3 worth of these would go a long way. Care and experience are necessary in selecting the fruits bought, for the proper bloom of the grape, the requisite ripeness of the banana or tomato, and the over-ripeness or otherwise of an orange are things to be learned, if possible, before the start.

Turn-over and Profit. The foregoing approximate estimate applies, of course, only to January trade. Fruit dealing is, perhaps, more a "season" trade than any other, and so much in the way of profit depends upon the weather and the scarcity or plentifulness of the fruits that no definite guide can be given. As the season goes on, blackberries, raspberries, currants, strawberries, apples, pears, and other English fruits have to be stocked, and it must never be forgotten that fruits are the most perishable of goods. A man must turn over his stock at the very least two or three times a week, and experienced fruiterers declare that, even with careful management, the waste may be put down in such a business as we are considering at £1 a week. This has to be taken cognisance of in the selling, but the quick turnover has its advantages in the fact that a man has always money in hand to carry on the business. The average profits on the return may be put at from 35 to 40 per cent.—below which the business is a perpetual struggle.

Fruit-growing at Home and Abroad. In this country, as everyone in the trade knows, British-grown fruit is preferred. The development of the fruit industry in Great Britain has been considerable in recent years. British grape-growing is extending annually, the principal districts being round Worthing, Swanley, Finchley, Uxbridge, Tottenham, Whetstone, and some places in Scotland and Wales. Plums are grown in Worcestershire, Cambridgeshire, Kent, Essex, Bedfordshire, Cheshire, Buckinghamshire, Norfolk, Gloucestershire, and Herefordshire, while there are well-recognised districts for cherries, gooseberries, raspberries, strawberries, currants, tomatoes, apples, pears, etc., in England and Scotland. There are important fruit markets in Liverpool, Manchester, Birmingham, Hull, Newcastle-on-Tyne, Glasgow, Edinburgh, Bristol, Cardiff, Cork, Belfast, and Dublin.

Colonial Fruit. It is probable, also, that many of the British Colonies in the Southern Hemisphere will attain an increasing importance as sources of both fruits and vegetables for the British market. Their particular sphere will be to give us many fresh fruits and vegetables when the season for our supplies of these grown in the Northern Hemisphere is past. Efforts are being put forth by many Colonial Governments to ensure that exported fruits shall be carefully selected and packed, so that a reputation for quality may be achieved. South Africa sends us now fairly large quantities of grapes, plums, pears, and peaches, and shipments have been made of apricots, nectarines, apples, and quinces. Some of the consignments have been experimental only, and the nature of the fruit trade prevents phenomenal development, such as is possible in manufactured products. Thus, its growth will be gradual.

The South African grape, known as the "Hanepoote," is a large berry of a sweet flavour, which ranks with our European "Muscatel." South African apples which have reached London are similar to the Californian "Newtown Pippin," and when the quantity rises to market demands will prolong the fresh apple season till the end of January. High hopes are not entertained of seed fruits, such as quinces, on account of public prejudice, engendered in some degree by fears of appendicitis. The pineapples of South Africa ought to prove popular in Great Britain. They are small, and may be sold as low as 6d. each, thereby making this delicious fruit the dainty of the man or woman with a small purse. The principal fruit product of Jamaica is the banana, but not more than a million bunches come to this country. The prices locally are 6d. to 2s. a bunch; in London, 3s. to 9s. Jamaica also exports from 80,000,000 to 100,000,000 oranges yearly, of which most go to the United States and Canada. The Jamaica orange deserves greater popularity than it has yet attained here; the price is 9s. to 15s. a case. Pineapples grow abundantly in Jamaica, but the growers have not succeeded in making profitable shipments to England. There is an unlimited supply of mangoes, for which the market in England is at present very restricted. They are sold here at 4s. to 6s. a dozen; locally, at a farthing each or less.

Structure of the Ear. Its Delicate Mechanism. Functions of the Tongue, the Nose and the Larynx. Care of the Voice. Articulation

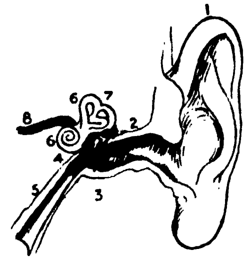
By Dr. A. T SCHOFIELD

HEARING

All are acquainted with the appearance and shape of the external organ which we call the ear, but few know anything of the complicated structure. We may, in a sense, be said to have six ears, three on each side; for each organ is divided into *outer*, *middle*, and *inner* ear.

The Outer Ear. The outer ear consists of the *pinna*, or ear proper, and the auditory canal leading to the middle ear. In man it is of far less use as an organ of hearing than in the lower animals, partly from the feeble power we have of moving it. There are, indeed, three muscles for the purpose, but they are so weak and so little under the control of the will, as to be of little use. The outer ear is, however, an ornament when well shaped, and collects some of the waves of sound [134].

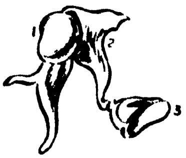
An ingenious observer states that the edge of the pinna vibrates to a perfect octave, as can be proved by drawing a small bow across it. The small knob at the upper and back part corresponds to the tip of the ear in animals, and in some men is almost a point.



134. DIAGRAM OF EAR
1. Pinna 2. Passage to (3.) Drum 4. Middle ear 5. Air tube to throat 6. Inner ear 7. Semicircular canals 8. Nerve of hearing

The Direction of Sound. The hearing of the ear can be improved and more sound waves collected by placing the hand behind the ear so as to enlarge it. Perhaps the chief use of the outer ear, as its general inclination is forward, is to indicate the direction from which the sound proceeds, as this is loudest when the ear is at right angles to it. The knowledge of sound direction is, however, very imperfect in many, for if a person be blindfolded, it is almost impossible for him to indicate whence any sound proceeds. In almost every detail of the sense of hearing, we are very deficient compared with other animals.

The Auditory Canal. The pinna leads into the *auditory canal*, an inch long, lined with stiff hairs and a bitter wax, to prevent the intrusion of unwelcome insects, and bounded at the end by the drumhead, or *tympanum*, stretched across it at an angle of about forty-five degrees. This membrane is the thickness of a piece of foreign note-paper, which will explain how easily it is injured by a hairpin or pencil. It will also be understood that all ear-drops are completely useless for any disease that lies behind this membrane, beyond which they cannot penetrate. It is unevenly stretched so as to take up vibrations of air from 30 a second up to 4,000. The head of a drum is evenly stretched and can only take up one set of air waves.



In Position

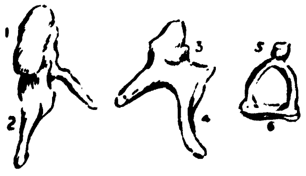
Natural Size

135 THE EAR BONES
1. Hammer 2. Anvil 3. Stirrup

The Middle Ear. Passing behind to the middle ear, we find it is half an inch high and one-eighth of an inch broad, something the shape of a button on its end. It is lined everywhere with ciliated (wavy) epithelium and is in direct communication with the air by the *Eustachian tube*, two inches long, opening into the throat. Air is thus freely admitted in health to both sides of the ear-drum, and in consequence it can vibrate freely. The failure of this through the stopping up of the Eustachian tube is a great and common cause of deafness. By holding the breath, and then swallowing, air can be forced up the Eustachian tube, causing a pressure that can be felt in these middle ears.

The outer wall of this chamber is, of course, formed by the *drum*; while in the inner wall opposite are seen *two smaller drums* stretched across two openings, the one being oval (Latin, *Fenestra ovalis*), and the other round (Latin, *Fenestra rotunda*).

Its Bones and Muscles. The *ciliated epithelium* always waves in the direction of the throat, so as to hinder impurities from collecting in this chamber. Stretched across the ear from the tympanum to the oval inner drum is a curious chain of three bones. They are called respectively, from their suggestive shapes, the *hammer*, the *anvil*, and the *stirrup-bone* [135]. The hammer (Latin, *malleus*), slung from the roof has its handle tightly bound down to the



136. ARTICULATION OF THE EAR BONES
1. Articulates with anvil 2. Lies against drum 3. Articulates with hammer 4. Articulates with head of stirrup 5. Articulates with anvil 6. Articulates with the oval drum of inner ear

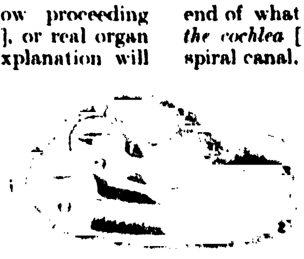
inner side of the tympanum, while the head rests on the head of the next bone, the anvil (Latin, *incus*) [136]. This, also slung from the roof, is articulated by one of its feet with the head of a well-shaped bony stirrup (Latin, *stapedius*), which in its turn has its base or foot-plate attached to the oval membrane on the internal wall. The purpose, if not the peculiar shapes, of these bones is sufficiently obvious. It is well known that all sounds are caused by vibrations, or waves, of air; these waves are collected by the outer ear, pass up the auditory canal, and, striking on the tympanum, cause it to vibrate. The vibrations move the air in the middle ear in a similar way, causing vibrations that strike on the membranes of the inner wall, so that some hearing is possible without the ossicles at all. The excessive accuracy necessary, however, to secure the hearing of speech is secured by this apparatus, every vibration being carried with absolute exactitude from the handle of the hammer, fixed against the tympanum by the plate of the stirrup, to the inner membrane; the speed of the vibrations is from 16 for the lowest note to 40,000 per second for the highest. Two muscles, one the smallest in the body, regulate these vibrations by tightening the drums. One of the two little muscles can both tighten the drum to a further pitch of acuteness in listening intently, or slacken it considerably if any loud sound is expected that might rupture it. The outer muscle is fixed in the same way to the stirrup to regulate the inner membrane.

137. THE INTERNAL EAR

1. Fenestra rotunda 2. Scala tympani 3. Scala vestibuli 4. Cupola 5. Vestibule 6. Saccule 7. Aqueductus vestibuli 8. Superior semicircular canal 9. Horizontal semicircular canal 10. Posterior semicircular canal

The Inner Ear. In now proceeding to describe the internal ear [137], or real organ of hearing, the very simplest explanation will be given, but at the same time the details are so complicated as to need close attention, and yet they are too interesting and important to be omitted.

Behind the oval drum or fenestra ovalis, to which the foot of the stirrup is fixed, is a small bony chamber called the *vestibule*, filled with fluid and containing a membranous bag, also filled with fluid. This bag contains some of the naked axis cylinder endings of the *auditory nerve* terminating in tiny bead-like heads, and in the bag are also a number of *sharp crystals*, which, being violently moved about during vibrations transmitted from the oval drum, probably strike these nerve ends with varying force.



138. SECTION OF COCHLEA

1. Modiolus 2. Scala tympani 3. Scala vestibuli

Where Sounds are Interpreted. In the vestibule by means of these crystals the intensity and distance of the sound is judged before the waves pass on to the true inner ear to be interpreted into notes or speech. The differing intensity with which these particles strike the naked nerves is supposed to tell whether the voice or music is loud or soft, whether near or distant, whether advancing or receding, and so on. This vestibule also contains five openings leading to the *three semicircular canals* (two of them having a common opening), which are very curious structures, made of bone and all opening into the vestibule, the first being *vertical* to the position of the body, the second *horizontal*, and the third *transverse*, so as to lie in the three directions of solidity—length, breadth and depth.

Human Spirit-levels. The canals are also lined with membranes filled with fluid, and are supposed to act like spirit-levels; they are connected with the cerebellum, or organ of equilibrium so that it is informed at once in which canal the greatest pressure exists, according to the varying positions of the head, and can automatically restore the balance by muscular action. It has been found that in certain diseases when one of these canals has been injured, the body has the tendency to roll over in a similar direction, either forward, or sideways, or backwards. The canals are also supposed to determine the position of the sound we hear, and the close connection they form between sound and equilibrium shows the value of a band to soldiers when marching.

Delicate Mechanism. Leaning against the internal wall of the vestibule and also against the round drum of the middle ear, is the broad end of what looks like a small periwinkle shell, *the cochlea* [138], which, instead of having one spiral canal, has two, the one (the *scala vestibuli*) opening into the vestibule, the other (the *scala tympani*) ending at the round opening in the middle ear. This double canal consists of two and a half turns, getting, of course, smaller towards the top, where the two communicate by a minute hole. Both are entirely filled with a limpid saltish fluid. This double spiral is separated by a fine membrane (the *basilar membrane*). The upper spiral of *scala vestibuli* is subdivided again by the *membrane of Reissner*, and the lower space is called the *scala media*. In this scala media, is the *organ of Corti*, or the real apparatus for hearing. Resting on the inner and upper surface of the basilar membrane, and continuing round and round to the top, are a continuous row of *little headed rods*, like pianoforte hammers, all graduated in size, getting smaller and smaller as they ascend, about 6,000 in number [139]. On the outer side of the membrane are arranged a corresponding number of *hollow pads*, into two of which three of these little hammers accurately fit, there being therefore about 4,500 of them, and it must clearly be remembered that every hammer and every pad is a living cell. These hammers and pads form a tiny spiral arch, decreasing in size all the way up. There are also two or three rows of stiff bristle-like cells along this canal, passing through holes like eyelet-holes in the membrane above, in which they can freely vibrate.

How Sound is Transmitted. All this is supposed to be an arrangement for receiving and interpreting in some way the vibrations in the fluid around received from the air waves of sound by the two drums of the outer and middle ears, and transmitting them through the two divisions of the scala vestibuli up to the top of the spiral, whence they return down the scala tympani to the round drum. There are three theories as to how sound is transmitted as vibrations to the auditory nerve. It is supposed that each hammer vibrates to a definite length of vibration, and thus interprets the sound. A second theory is that it is the stiff bristle nerves that are thus tuned to take up the vibrations; but attention has lately been drawn to the structure of the basilar membrane itself, on which these both rest, and which is believed to consist of an infinite number of strings of different lengths, stretched side by side all the way up, and able, like violin strings, to respond to different vibrations; and the third theory is that this membrane is the true organ of hearing, the hammers, etc., resting on it serving merely to "stop" or deaden the strings. It is still a moot point as to whether the hammers, bristles, or membrane are the true organ of hearing. All three, however, are directly connected with the auditory nerves that run up the central pillar round which the spirals turn and transmit all vibrations to the auditory centre in the brain.

Sound Waves Heard and not Heard. The waves of sounds are waves in the air, very like waves at sea, varying from the lowest note we can hear, which are waves 64ft. long, and 16 to the second, to the highest, which are waves one-third of an inch long and 38,000 to the second, each octave higher having waves twice as fast and half as long as the fundamental note. There are plenty of sounds too shrill for our ears to receive—the squeal of a bat, the chirp of a cricket, are thus often unheard by us. By the aid of a Galton's whistle, notes can be produced too shrill for the human ear, though they can be easily heard by a horse or a dog.

Value of Two Ears. Just as in the eye, if the centre of hearing in the brain be injured all the elaborate apparatus we have described is useless. The ear has been compared to a telephone, as both depend entirely in the same way on vibrations. The value of two ears is that we can hear two things at the same time, as a clock striking and a conversation. We can also receive sounds equally well from either side of the head.

There is a distinct difference between *hearing* and *listening*, just as there is in the eye between *seeing* and *looking*. When we listen the brain centre is on the qui-vive, and all the apparatus is braced up to receive sounds, perhaps otherwise unnoticed, though not unheard.

Noises and Notes. The difference between a noise and a musical sound or note is that in the latter the waves are regular and of uniform length; in the former they are a mixture of different lengths.

From this brief description of hearing, it will be noted that the sound waves are transmitted by three media—solids, liquids, and gases. In the outer ear the waves are conducted partly by the air and partly by the cartilages of the ear and the bones of the head. The chain of bones transmits them to the inner ear, whence every vibration is taken up finally by fluid which, striking in various ways on the bare terminations of the auditory nerve, cause the perception of sound in the brain.

TASTE

Pimples on the Tongue. The tongue, the organ of taste, is covered with three varieties of papillæ or pimples. The first, called *filiform papillæ* [140], are thread-like elevations that abound over the middle of the tongue. They are sharp, whitish, and pointed. In a cat they are very hard, like small thorns or spines, while in the lion or tiger they are of terrible size, like rows of teeth, and capable of stripping the flesh off a bone with a single lick of the tongue. They are principally used in man for rasping the food against the furrowed roof of the hard palate.

The second class of pimples on the tongue, called *fungiform papillæ* [141], are mushroom-like elevations; these are scattered all over the tongue, and especially towards the front. They are round and very red, the skin over them being very thin. They contain touch corpuscles, and are really a delicate part of the great sense of touch. They can at once discern the quality of what is in the mouth and if it be too hot or cold.

The third class of pimples are much larger and form a striking object at the back of the tongue. These are the *circumvallate papillæ* [142], or the "circular trench" pimples. They owe their peculiar name to their extraordinary shape. They are arranged—ten or twelve in number—right across the back of the tongue in the form of a V, with the point backwards, so as to catch all the food as it passes into the pharynx before it is swallowed. Each one consists of a flattened elevation with a slight central depression, and is surrounded by a depression like a trench (hence the name), and beyond the ditch is a slight circular elevation like a wall. Opening into the bottom of this trench are the numerous orifices of the glands which secrete a very powerful juice of great solvent power; while all along the sides, embedded in the walls, are bodies like oranges, called *taste buds*. From the top of each of these oval bodies, projecting into the trench, is a circular row of stiff hairs, making the whole rather like the head of a thistle. Part of all the food that is eaten falls into the trenches of these papillæ and part is dissolved; and then it is supposed that the ultimate particles strike against the hairs, which are really naked "nerve endings," but look like the feelers of sea anemones, the process being similar to that in the sacculus in the ear, where the crystals strike the nerve endings. The vibrations are conveyed to the taste buds and thence by nerves to the taste centre in the brain.

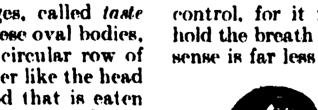
(For rasping)
1. Artery 2. Vein

How we Taste. In speaking of all these organs of special sense—whether of touch, taste, smell, hearing, or sight—it must be remembered that the special apparatus we described is only an arrangement for accurately transmitting the peculiar vibrations or sensations to the brain which alone feels, tastes, smells, hears, or sees; for, as has been shown, if certain districts of the brain are diseased, however perfect these apparatuses may be, nothing is perceived. Consider for one moment the marvels of a "special sense." The salt-cellar, for instance, has been filled up in mistake with sifted sugar, and you put some on the side of your plate and proceed to eat it with your beef. You believe it is salt, it looks like salt, and you use it as such, and you expect to discern its taste on the meat in the mouth. Some minute portions dissolved in the trench strike against the projecting nerve ends, and in some inscrutable way send up vibrations to the brain quite different from salt; and so forcible and strong is the effect in the taste centre that, against your belief and the endeavour of the senses, you declare it is sugar.



142. CIRCUMVALLATE PAPILLA
(For tasting)
1. Artery 2. Vein 3. Nerve
4. Water gland 5. Muscle 6. Taste buds at sides of trench

SMELL

The sense of smell really resides in the upper part of the nose, and here the olfactory or smelling nerves are situated. They project downwards in innumerable fine hair-like endings into the upper part of the nostrils, and are connected above with two large bulbs of brain matter in the under surface of the cortex of each hemisphere.

All parts of the nose can *feel* acutely; but if we wish to *smell* anything, we sniff up the odour into the upper part of the *nares*, or nostrils [143].

How we Smell. *Odours* are either suspended in exceedingly fine particles in the air or in gases so thin and imperceptible that it is only by the sense of smell they are discovered. The odour must be dissolved in the secretions of the nose before it can be smelled. Hence, with both taste and smell, if the article be absolutely insoluble, it cannot be discerned. If the nose be dry, as in fever, the sense of smell is lost; or, if there be too much secretion, as in a heavy cold, it is much impaired. The use of the sense of smell is a good deal under our own control, for it requires an effort of the will to hold the breath and take a deliberate sniff. This sense is far less keen in us than in animals.

Flavours. Some smells, such as those of pepper, ammonia, and acids, can hardly be distinguished from common sensation; and others closely connected with tastes we call flavours. The delicacy of the olfactory sense is most remarkable, for the most minute traces (one thirty-millionth of a gramme of musk), quite impossible to discern by any other means, can be smelled.

141. FUNGIFORM PAPILLA
(For touching)
1. Artery 2. Vein
3. Nerve

Pleasant and unpleasant odours are merely questions of judgment, just like colours and sounds; and what constitutes the sensation of pain or pleasure to which they give rise, is not fully understood.

SPEECH

Turning now to the important faculty of speech, we will try, very briefly, to describe, first the mechanical apparatus of the voice, then the production of air-currents, and the vocalisation and the articulation that produce speech, giving also a few hints on the use and management of the voice.

Three Stages. The whole process culminating in speech may be clearly divided into three parts. First, the production of the needed current and volume of air; next, the production of sound; and, thirdly, the moulding of this sound into words. For the first the lungs are needed, for the second the larynx, and for the third the mouth—*i.e.*, the tongue, teeth, and lips.

The two former may be roughly compared to the common harmonium, where sound is produced by the wind being forced up from the air-chest below through the vibrating reeds above. There is, however, in the harmonium no further apparatus to form these sounds into words, and thus to correspond to the mouth. Moreover, for all the notes of the different octaves (say, three, which is the average compass of the human voice), no fewer than 36 separate reeds are needed; whereas, for the same compass in the human organ but one set of reeds is used, as there is a mechanism to alter it to all the different tones required. We know that the lungs are contained in the thorax or chest; the larynx, or voice-box, in the neck, a prominent part of it indeed, just where the vocal cords are affixed, being called the Adam's apple.

Construction of the Larynx. The larynx, or voice-box, is situated, as we have said, in the neck, and leads from the back of the mouth to the top of the trachea, which brings the air from the two lungs below. It is an open tube with a lid, and is about 3 in. long. The walls and lid are composed of cartilages. The largest is that forming the centre part of the tube, the *thyroid*, and is the least movable; the *epiglottis*, or lid, and other cartilages, to which are attached numerous muscles, being freely movable in various directions.

143. RIGHT NASAL FOSSA

Across the middle of the tube, from the front to the back, are stretched two flat bands, fixed together at the front, but capable of being separated behind, where they are attached to two movable cartilages called *arytenoid*. When these two bands are brought together, they form a sort of flat drumhead or septum that shuts off the upper from the lower half of the larynx so perfectly that even a drop of water cannot pass through; while, on the other hand, they can be separated so widely that the opening is triangular, or, rather, the shape of a spearhead, the point being forward and the broad part backward. These bands are the true vocal cords, and the air that passes through the narrow chink between them is thrown into ripples or air waves by the vibration of their edges, and these waves, when they strike on the ear, produce sound. The two vocal cords in the larynx, therefore, by their vibration, are the true voice or sound-producers in the higher animals.

The Vocal Cords. These are composed of elastic, muscular, and fibrous tissue, and are of a glistening white appearance, as may be clearly seen by a small mirror placed at an angle in the mouth, and called the laryngoscope [144].

Above them, on either side, the walls of the larynx make a sort of pouch, the upper parts of which, bulging into the larynx, form two folds above the true vocal cords, and, as they slightly resemble them, are called the false vocal cords. They act, to a certain extent, as dampers or deadeners of sound, though they never actually touch the cords; while the pouch between secretes a considerable amount of glairy fluid which serves to lubricate the cords and keep them from getting dry.

Action of the Tongue. At the top the lid, or epiglottis, of the larynx, which is hinged in front and folds down backwards over its mouth, is fixed to the under side of the back of the tongue in such a way that whenever the tongue is carried forward it is raised and opened, and when the tongue is carried back, as with food, it shuts tightly down, allowing all food and drink to pass over it and down the gullet behind. It closes over the larynx so completely that not a drop of water can pass down into the windpipe. In breathing, as well as in speaking or singing, it is, of course, always open, while in swallowing it is tightly shut. We cannot, therefore, breathe while we swallow, nor swallow while we breathe. Such then, briefly, is the construction of the larynx. It only remains for us to add that the whole larynx, as well as the windpipe, lung tubes, and back of the throat, are lined with ciliated epithelium in such a way as to pass up into the mouth any particles that may settle upon them. In nearly all affections of the air passage this membrane is more or less destroyed for the time being.

Voice Production. The voice is produced by the rushing of the air through the narrow chink between the bands or "cords," which can be plainly seen by anyone who can use the laryngoscope; on the other hand, these bands can be seen widely open and far apart during quiet respiration [145].

The narrower the chink the greater the pressure of the air as it passes through and the higher the note produced. By the varying tension and approximation of these cords a range of sound extending on an average to three octaves can be formed.

In the adult male the cords are nearly one-third longer than in the adult female.

An imitation of the voice apparatus can be made by stretching across the top of a glass tube two bands of indiarubber close together. If these are blown through with a certain force, a sound will be emitted, higher or lower, according *to the tension.*

The action of the cords as well as the closure of the top of the larynx being regulated unconsciously, it would appear at first sight that we cannot do much voluntarily in arranging the production of the voice. Such, however, is far from being the case. We can, in the first place, see that the delicate structures are not in any way injured by our carelessness; and, secondly, we can, by practice, regulate to an exact nicety the action of the cords so as to produce instantaneously the exact sound required.

Breathing through the Nose. A great point in the care of the larynx is to breathe through the nose, and not through the mouth. The mouth is made for expiration, specially in speech and vocalisation, but not for inspiration, for which the nose is specially constructed. The mouth should be kept shut, but it is still possible to breathe through the nose with the mouth wide open when once the habit is acquired; and, on the other hand, there are certain passages in singing where, owing to the elevation of the soft palate, breathing through the mouth is necessary. If the nose cannot be or is not regularly used as "the" respiratory passage, a doctor should be consulted at once, as there is something blocking the natural passage—enlarged tonsils, adenoid growths, or some malformation.

Care of the Voice. Sudden changes of temperature are extremely injurious to the vocal cords, especially after prolonged use. Great care should be taken by speakers and singers against chills or draughts of cold air after using the voice, and also after leaving close or heated rooms. A loose muffler over the mouth and nose when first going out is a wise precaution. Air too dry or too damp is also injurious in public speaking. Air, again, overladen with dust or smoke or fog is most injurious to the vocal organs, which must suffer, if the voice be much used under such circumstances.

144. SUPERIOR APERTURE OF LARYNX

Showing the glottis during emission of a high note

1. Root of tongue 2. Epiglottis 3. Posterior wall of pharynx 4. Rima glottidis 5. True vocal cords 6. False vocal cords

No loud speaking or singing should be persevered in if the throat be at all sore or relaxed, or if there be a severe cold in the head. Neglect of this is one of the common causes of clergyman's sore throat. Of course, as we have already said, any definite chest affection, such as bronchitis, precludes all public speaking.

Management of Expiration. So far, we have spoken of inspiration in connection with the larynx; let us now consider, for a moment, expiration.

We have already said this is to be carefully economised and none of the air wasted. The exit of the air can be retarded by the approximation of the vocal cords. But this, of course, raises the pitch of the voice or note. The secret of keeping at the same note and yet retarding the exit of the air is by the approximation of the false vocal cords above the true. This can *only be done*, as we say, instinctively, or, rather, unconsciously, by practice; and the retardation of the expiration, so as only to use what air is needed and keep some well in hand, is one of the secrets of ease in speaking and singing.

There should be no strain in singing or speech. Loudness is not necessary for force or beauty, but a good volume of air is.

Pitch. The pitch in speaking is of great importance, not only to the speaker but to the hearers. With regard to the latter, it is not too much to say that the conveyance of thought by speech depends not only on the words, but the tone and pitch. It is wonderful what a power to sway thought a well-pitched and modulated voice possesses. Of course, in singing, the pitch is always considered; but in speaking this is rarely done, though its importance to the speaker is as great as to his audience. A wrong pitch strains the voice and the vocal cords. We all have for speaking what may be termed a natural pitch of voice, just as we have a natural pace for walking, and that is the pace or pitch which we can use with the greatest ease and without strain.

Public Speaking. There can be no doubt that absolute ignorance of the simple laws of voice production still prevails even amongst our most constant speakers, and it is not much to the credit of the twentieth century that amongst large bodies of men such as clergy, barristers, etc., whose living depends very largely on their voice, many should fall out of the ranks altogether, or, at any rate, suffer needless pain and misery for want of a few lessons on this most useful art. At Athens every student was taught how to speak properly and to use the voice with ease and effect, as being essential to health, quite apart from its special value to speakers.

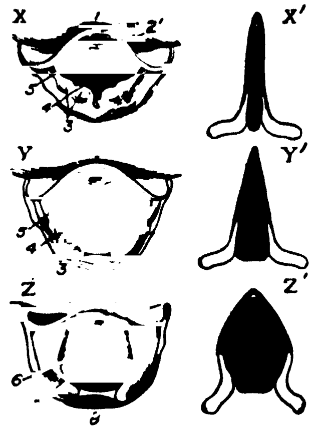
We have little doubt that for a child of a consumptive tendency there could not be a more healthful and curative—or, rather preventive—exercise than a thorough course of instruction in voice production by a competent teacher. At any rate, it is beyond dispute that such a course should form an integral part of the education of every public speaker. This is especially the case with the clergy. They are the class whose vocal organs are most severely tried. The buildings in which they speak are often far more trying than concert-halls or lecture-rooms, which are built to carry sound. The vaulted roof, the long aisles, the cold, vault-like air at the early morning service, the close stuffiness of the crowded evening church, the incurable and ever

present draughts, are all bad. Worse still is the "pulpit voice," artificial and strained; it is bad for the larynx and throat, and wears them out, while a natural voice would continue in full vigour and tone.

Articulation. Passing on now to the third part of speech production, that of articulation in the throat and mouth, we may point out that it consists of at least two processes. First, the moulding or shaping of the air-vessel into the various vowel sounds by the opening and closing of the throat, "ah" being sounded when the throat is open to its widest, and "oo" when it is most nearly closed, the other sounds falling in between. Secondly, the cutting off of these sound waves into different lengths, to form words or syllables, by means of what are called consonants, which are closures and sudden openings that first stop and then allow of the passage of air and of the vowel sound by the closure of the lips as in "m," or with the tongue against the front of the hard palate and teeth as in "s," or against the front of the hard palate as in "t," only the opening of the fauces as in "k" or "g," and so on—each consonant giving a characteristic "click" or other sound of opening.

Vowels alone are true vocal sounds that can be prolonged as long as the mouth remains in the same shape, and as long as the current of air continues, the pitch being, of course, determined by the vocal cords.

It is all important to enunciate and articulate clearly; all the vowel and consonant sounds should, therefore, be carefully practised with the greatest accuracy; such practice, like all other vocal exercises, is best done before a mirror.



145. THE LARYNX AND GLOTTIS

X and **X'**. Nearly closed for highest notes **Y** and **Y'**. Open for quiet breathing **Z** and **Z'**. Open very wide for gaping **1.** Base of tongue **2.** Tip of epiglottis **2'.** Thyroid cartilage **3.** Triangular cartilage to which vocal cords (**4.**) are fixed **5.** False vocal cords **6.** Inside of larynx **7.** Wind pipe **8.** Point of gullet

The Aspirate. The letter "h" is often an insuperable difficulty. It is, perhaps, best overcome by expiring forcibly against a window-pane and adding some syllable such as "at" or "ot" to the expiration. The expiration is then gradually shortened till it becomes "hat" or "hot."

Another difficulty is stammering or stuttering. In minor cases this is cured by slow, deliberate formation of each word until the habit is broken. More severe cases require special treatment, which is now admirably conducted. Nearly all are curable. "Take care of the consonants, and the vowels will take care of themselves."

For proper speech the teeth should be complete in number and kept in good order. If the tongue is swollen or sore, or the tonsils enlarged, speech is difficult. In the latter case, enlargement of the tonsils, the removal of the same portion under surgical advice is of great value. The throat also must be in good order.

Effect of Food and Drink. Food and drink greatly affect the condition of the lining membrane, both of the mouth and throat, and indirectly of the vocal cords. First and foremost is the abuse of alcohol. No one who speaks or sings much can indulge freely in alcohol with impunity, while in many even a small quantity is prejudicial, as the effect on the stomach and pharynx is distinctly bad. The very voice of the habitual drunkard speaks of the ravages caused by alcohol. In small doses, well diluted and taken with food, alcohol is not itself harmful to the voice organs when they are in health, but if they are diseased even a very small quantity may do harm. Strong tobacco, especially in the form of cigarettes, is injurious to the voice.

Much hot tea, in the same way acting on the digestion, is not beneficial to the voice; coffee or cocoa, or cold tea, especially if not too strong, are not harmful. It is not well to use the voice publicly at any length sooner than two hours after a full meal.

Two great practical defects in speaking and singing may be noticed. One is that the mouth is often not sufficiently opened, and the other is that the voice is often dropped two or three or more tones in pitch towards the end of a sentence so that the words are quite lost at a little distance.

The secret of easy public speaking is the understanding of respiration so as to retard it at will, the use of the right pitch, modulated tone, and the natural voice, avoiding a forced or artificial voice, monotones, and all strain. Speak in an erect position, eat suitable food, and retain as far as possible good general health and sound nerves.

The "British Medical Journal" enumerates four special points on the right use of the voice:

1. Thorough control of the motive power of the voice and breath.
2. A proper attack of tone.
3. The education of the resonant cavities of speech.
4. The right pitch.

With this consideration of the organs of the senses we reach the conclusion of our survey of the human being from the physiological point of view; and we shall now turn to a subject of vital concern in all our lives—the prevention of disease and the maintenance of the body in health.

MACHINE MOULDING

The Processes and Appliances of Machine Moulding. Examples of Moulding Machines and their Advantages. Wheel Moulding

By JOSEPH G. HORNER

THE highest development of moulding, that by machine, is one that grows very rapidly. It is divisible under two groups—one devoted to general work, the other specially to toothed wheels, the latter constituting a very much smaller group than the former.

Types of Moulding Machines. In reference to the first, there are some dozens of distinct types of moulding machines now made, and operated either by hand, as in **98** and **99**, steam, water, or compressed air. Patterns may be rammed by the machine, or by hand, but they are always withdrawn under the control of the machine slides. In the clean delivery thus obtained much of their value lies. In England and Germany a large amount of hand ramming is adopted in machine moulding. In the States ramming is more often done by mechanical means. There would be no special difficulty in compressing sand by mechanical means over a perfectly level surface: but the surfaces of patterns are seldom level, but of more or less irregular contours, and the difficulty of mechanically ramming uneven surfaces is that the sand inevitably becomes harder and softer in different localities. It is therefore necessary to prepare special pressing plates in such cases, corresponding at least approximately with the contours of the patterns to be pressed. As the cost of these can be incurred only when a considerable number of similar moulds are required, this helps to explain why hand ramming is preferred in the majority of cases.

The patterns moulded in machines are attached to a plate—or often cast solidly with a plate—the opposite faces of which provide the faces upon which the mould joints are rammed directly, so saving the trouble and time of making sand joints. And again, it is usual, when possible, to mount several small patterns on one plate to increase the output per mould.

We can better understand the general methods of machine moulding if we consider in brief those methods which lead up to it, and of which it is the complete development. These are bottom or joint boards or turn-over boards, and plate moulding.

Bottom Boards. Turn-over boards, bottom boards, or joint boards, as they are variously termed, are used to save the trouble of making the sand joints each time the pattern is rammed up, or else to sustain a flimsy pattern, or to fulfil both functions at once. Different forms of turn-over boards are made to suit requirements. Perfectly flat boards are used for any flat-jointed patterns, and kept in foundries in different sizes to suit moulding boxes of various dimensions, the pins passing either through holes in the board, or beside its edge. Any flat patterns, jointed or unjointed, may be laid upon these to keep them straight while being rammed up, as pipes, columns, cylinders, thin plates, and such like. Fig. **103** shows such a board (A) maintained truly with battens. It is not quite the simplest bottom-board arrangement, because instead of a complete pattern being used, a set of half patterns is shown, and there will be another board with half patterns exactly like this for the bottom box. A halfway stage between this and the absolutely plain board is the board of the brass moulder, cut out to drop unjointed patterns into. In this, these handwheel patterns would then be complete, but solid, and sunk into the board to their central planes. Then one half box would be rammed over them, and turned over, and the board taken away, leaving the other half of the patterns exposed to be rammed. In **103**, however, there are two sets of half patterns on different plates, and no turning over is done. In this figure, note may be made of the way in which the box is confined by the corner blocks, of the runners radiating from the central ingate, and of the lifters hanging from the bars. In the upper or plan view, the bars are broken away to show the pattern arrangements clearly.

In another stage, if irregularly-shaped sand joints are required, blocks are put on the board, of shapes corresponding with the sand joints. Plate moulding in its simplest form is embodied in these arrangements.

Metal Plates. Figs. **100** and **101** show a more advanced stage. Here the plates are of iron, and the patterns are of iron or of brass, and attached to opposite sides of the plates, so that if the plate thickness were removed, the pattern portions would make up a complete pattern. In each case, sprays of runners are screwed or riveted to the plates. Fig. **102** illustrates pattern parts and plate cast together, a method adopted when the work is standardised, and in constant service from year to year.

Advantages of Plate Moulding. It should be obvious that this system of plate moulding is vastly more economical and accurate than hand moulding when much repetition work has to be done. Its employment does not necessarily involve the use of a moulding machine, since there is a large amount of work of this kind done without the aid of the latter, the machine being mainly a mechanical aid to facilitate the better delivery of the pattern. Plate moulding is an extension of the use of the turn-over boards; but in the case of such boards, the pattern, either in whole or in halves, is made distinct from the board, and in the

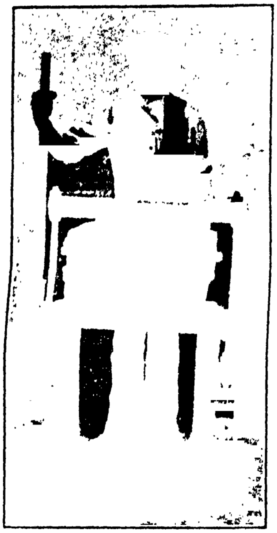
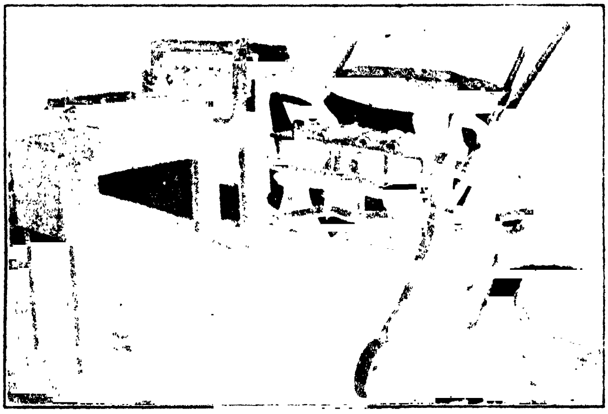
MOULDING MACHINE AND PLATE MOULDING

simplest case the latter merely forms the first sand joint face—namely, that of the bottom box part, upon which the top face is rammed; and the whole, or half pattern, as the case may be, remains in the bottom part, while such portion of it as comes in the top is also rammed at the same time as the top joint face. But in plate moulding [100–103] the faces of the sand joints do not come into contact until the final closing of the mould for casting, for each face is rammed against the joint board or plate, and the pattern sections which belong to top and bottom respectively are fastened to, or are integral portions of the board or plate itself. The principle is simply this: that *whatever shape the pattern is, those portions into which it is divided by the plate would, if* the plate were removed, differ in no wise from any ordinary pattern. The plate is therefore simply a piece interposed between those portions of the pattern which come in the top and the bottom boxes.



104. HAND MOULDING MACHINE (Samuelson & Co., Ltd.)

Patterns for Plate Moulding. In much work of this character, wood as a material of construction [103] is discarded altogether, and iron employed for plate and pattern [100–102], and often the whole is combined in one casting, as 102, which shows plate containing four hand wheels with their runners. A pattern is first prepared in wood, from which the plate with its lugs, runners, and pattern wheels is moulded and cast. The whole is then got up by filing, turning, or other suitable means, the amount of work bestowed upon it varying with the custom of the shop; some machining every portion, others leaving the faces rough, as cast, and only truing and smoothing the edges which draw vertically. After tooling, the pattern and plate are rusted over with sal-ammoniac and water, warmed, and well beeswaxed, to impart a smooth skin for delivery from the mould.



105. PORTABLE HAND MOULDING MACHINE (The Adams Company)

A secondary advantage of the use of metal-plated work is that the evils which are more or less inseparable from the warping of timber are eliminated, and better, smoother surfaces are obtainable, and consequently better deliveries and smoother castings.

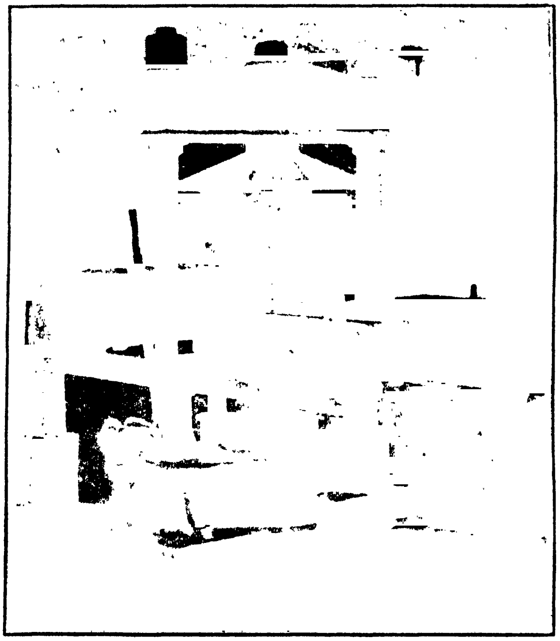
Moulding by Machine. If now, instead of withdrawing the pattern from the mould by hand or with a crane, which owing to its unsteadiness is a frequent cause of breaking down of the moulds, the plate be fitted on the table of a machine and the mould withdrawn from the pattern by a lever or a ram, perfectly plumb and steadily, the last risk of fracture of the mould is well-nigh eliminated, and this marks the perfection of plate moulding.

Examples of Moulding Machines. Figs. 98 and 99 illustrate in front and side elevations and part sections one type only among the many moulding machines. It is one of the most improved designs, in which the ramming, or, rather, pressing, is accomplished by power. The machine framing comprises two sides connected with horizontal stretchers. Between the table A and the crosshead B the sand is pressed into the moulding boxes, C C, which are fitted through intermediate plates with pins to the turnover table D. A presser board E attached to the crosshead pushes the sand into the box part which happens to be uppermost, the surplus sand necessary being confined by the loose frame F. The pressure is imparted by the hand lever G actuating the pinion H and toggle levers J K. The pattern and plates are lifted from the box by the counter-weighted lever L actuating the side rods M M, in the bosses of which the table can be turned over for ramming the two box parts. The crosshead B is swung aside during the filling of the boxes with loose sand, being pivoted by the rods N N.

Fig. 104 shows a plain type of machine in operation. The pressing is done by the top crossbar, pulled down by levers actuated by the long handle seen grasped by the attendant. The pair of boxes are seen between the table and the presser-bar.

In 105 we have a development of much value, the portable machine, running on wheels, so that it can be easily pushed about the foundry to any convenient location, leaving the moulds in its wake as they are made. The half-patterns are seen on the machine table, with the presser board thrown back, while on the bench alongside are the moulds produced. Underneath the bench will be noted several of the steel bands or frames mentioned later in connection with snap flasks.

Hydraulic Moulding Machine. A hydraulic machine is illustrated in **106**, consisting of a press, with ram below and crosshead above. Above the ram the boxes are carried on rails, so that they may be run back from beneath the crosshead, and the sand filled in conveniently. Then one box is pushed along to the centre, and the rise of the ram lifts the box and presses the sand against the opposition of the plate attached to the top crosshead. Lowering the ram withdraws the pattern. In addition to the power obtained by hydraulic pressure, there is the further advantage in this class of machine that as many as four men can be set to work —two filling and pressing, and two removing the boxes and placing them together.



106. HYDRAULIC MOULDING MACHINE

Where Machine Work Scores. The examples which have been given are comparatively plain, the better to illustrate the elements of plate and machine moulding. But the full advantages of the system are most apparent in patterns of intricate forms—that is, which involve more sleeking and shaping of joint faces, etc., on the part of the moulder, more work in cutting of runners; also patterns which are moulded in very large quantities by firms who deal in specialities, and which, being usually of small dimensions, can be and are moulded several at a time on a single plate. The highest economies are secured when patterns of small and medium dimensions are grouped on plates along with their runners, and when joint faces are not plain. Patterns which are not cored, or cored only to a small extent, are more economically moulded than those in which many intricate cores have to be fitted and properly secured. Shallow patterns, and patterns without vertical edges, deliver best, but deep patterns with vertical faces are eminently suited for plate or machine moulding when a stripping plate is employed.

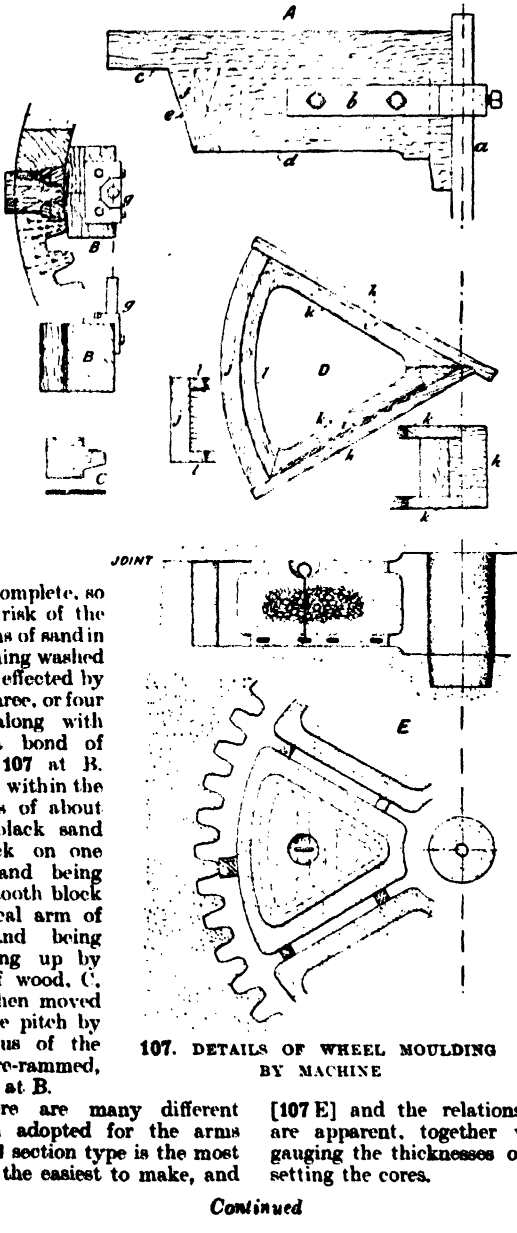
Wheel Moulding. The moulding of toothed wheels by machine means that a complete pattern is not required, and that the employment of mechanism produces more accurate results in the pitching or spacing of the teeth than can be ensured by hand work with a full pattern.

The wheel moulding machine is a dividing machine, having change wheels and worm gear for the pitching, together with mechanism for operating and withdrawing the tooth block. The cores for the arms are made by the usual methods of core making, and inserted in place by hand.

The general process of wheel moulding is as follows. The moulder is provided by the patternmaker with all necessary parts, such as tooth blocks, core boxes, etc., which vary with each type of wheel—spur, bevel, worm — and with the shape of the arms, the presence or absence of shroudings, etc. We can take only the case of a plain spur wheel with a plain top. The top box is rammed distinct from the wheel mould upon a plain level bed of sand, and calls therefore for no remark. If the wheel be large and made in the floor sand, a coke bed is provided underneath, and the whole area of the wheel is vented down to this bed. Small wheels are moulded in a bottom box. In the case of the spur wheel selected [**107**] the bed and the top joint face are made with a striking board A. On it the half section of the wheel is marked as a guide to the moulder in setting the cores. It is attached to the striking bar *a* by a strap *b*. It strikes *c*, the top joint face, *d*, the bottom of the bed, and *e*, a wall of sand, at 2 in. or 3 in. distance away from the tooth point, leaving a space *f* for the reception of the facing sand, to be rammed within and around the tooth spaces. In bevel wheels it is better to cut the board precisely to the bevel and diameter of the tooth points.

Formation of the Teeth. The ramming of the tooth block B follows. The one shown has two teeth; but many contain three or four. The more teeth used the greater the precision demanded, because each tooth space must be an exact counterpart of its fellow. Each space has, moreover, to be rammed up with the same expenditure of labour as any other, so that the only time saved is that in elevating the block.

Having a tooth block, the spur B, shown or a bevel wheel block bolted to the carrier *g* of the machine, the radius is set by means of a strip cut to extend from the central striking bar *a* to either the root or point of the tooth, and the arm is permanently clamped in the position corresponding therewith. The block is lowered by means of the vertical slide of the machine until it touches, and just presses upon the bed struck by the board A, and the ramming up commences. The ramming must be done so that the connection between the tooth spaces and the outer body or wall of sand struck by the sloping edge of the board A shall be complete, so that there will be no risk of the narrow pillars or sections of sand in the tooth spaces becoming washed away. This union is effected by means of nails—two, three, or four being rammed in along with the sand to form a bond of union, as shown in **107** at B. Facing sand is rammed within the teeth to the thickness of about 1 in. or 1½ in., and black sand behind, and a block on one side supports the sand being rammed there. The tooth block is lifted by the vertical arm of the machine, the sand being prevented from pulling up by holding a flat piece of wood, C, on its surface. It is then moved a distance equal to the pitch by the dividing apparatus of the machine, lowered and re-rammed, and so on, as indicated at B.



107. DETAILS OF WHEEL MOULDING BY MACHINE

The Arms. There are many different methods of formation adopted for the arms of spur wheels. The **H** section type is the most common, because it is the easiest to make, and the strongest. But other forms are often adopted either because the wheels are too small for **H** arms, or because that type would be out of harmony with adjacent gears; because wheels have to replace broken ones, or they have to be cast against something else which necessitates some other shape, or on account of the designer preferring an older type of arm. We can take only the moulding of a spur wheel with **H** section arms.

As usually made, the core-box is of the form shown at D [**107**] in plan and part sections. The two sides *h h* are notched together at the angle required for the arms, 60 degrees if for six arms, 45 degrees for eight, 90 degrees for four, and, the inner faces corresponding with the centres of the ribs; the thickness of ribs, *i*, is equal to half the thickness of the arms. The inside of the sweep *j* corresponds with the inside of the rim of the wheel, and the flat arms *k k* and inner ribs *l l* are divided to allow of delivery of the core. The core being rammed up, the screws which connect the sides with the sweep are withdrawn, the sweep *j* drawn away horizontally, the sides also drawn in the same manner, and the core left standing on the ramming board or bed.

The mould is shown in section and plan [**107** E] and the relations of the several parts are apparent, together with the method of gauging the thicknesses of arms and rims when setting the cores.

Continued

A SHORT DICTIONARY OF TERMS IN FOUNDRY WORK

ACID STEEL—Steel made from non-phosphoric ores.

Air Belt—The belt encircling a cupola, through which the blast is conveyed to the tuyeres.

Air Furnace—A furnace which utilises the natural draught of a chimney.

Alloy—A mixture of two or more metals, effected by fusion.

Aluminium—Used in numerous alloys. It exercises a cleansing effect.

Anchor—A moulder's chaplet.

Angle Board—Used by pattern-makers for planing angles, hollows, or fillets in.

Angles—Strips of triangular section used for fitting in corners in patterns, and for strengthening castings.

Annealing Oven—Used for the decarbonisation of malleable iron castings.

Apple Tree—Used for cogs of mortice wheels.

Arc Pitch—The pitch of gear wheels measured round an arc of the pitch line.

BABBITT METAL—A white metal used for lining bearings.

Back Plate—A cast-iron plate bolted to the back of a foundry box, for vertical casting.

Bare—Slightly under exact size.

Barrow Ladle, or Sulky—A foundry ladle mounted on a barrow framing.

Bars—The stays, or cross-pieces of moulding boxes.

Basic Steel—Steel made from phosphoric ores, in a converter or furnace having a basic lining (lime).

Bastard Wheel—A wheel which, bearing with another, is not of correct pitch or bevel.

Bead Sleekers—Moulder's tools for smoothing the impressions of beads.

Bed Charge—The bottom charge of coke in a cupola furnace.

Bedding-in—Moulding patterns in the same position in which they have to be cast, without a bottom box.

Beeswax—Used for coating iron patterns to prevent them from rusting.

Bellows—Employed for blowing particles of loose sand, dust, and blackening out of moulds.

Bench—Used by pattern-makers, moulders in small work, and by core-makers.

Bench Rammer—A small rammer used for moulding at the bench.

Bench Work—Work done at the bench, to distinguish it from that done on the floor.

Bevel Wheels—Toothed gears, the pitch planes of which form conic frustra.

Blackening—Charcoal dust, or plumbago, used for dusting foundry-moulds to prevent sand burning.

Blacking Bag—A muslin bag from which blackening is dusted over the surfaces of moulds.

Blacking Mill—A rotating cylinder containing rollers, or balls, which crush charcoal into dust.

Blackleading—Sometimes patterns are treated thus to facilitate their delivery.

Black Sand—The old sand of the foundry floor.

Black Wash, or Wet Blacking—A mixture of charcoal or plumbago with clay water, washed over the surfaces of moulds.

Blast—Air supplied under pressure to melting furnaces.

Blast Furnace—A furnace ranging from 80 ft. to over 100 ft. high, in which iron is reduced from its ores.

Blow—The period during which blast is being brought into a melting furnace, or the act of bringing it in.

Blower—A rotary machine in which an artificial current of air is produced by positive pressure.

Blow Holes—Holes in castings caused by the entanglement of gases in the mould at the time of pouring.

Body Core—A main core.

Body Flange—A pipe flange fitted on the body of a pattern.

Bosh—A tank of water for foundry use.

Boshes—The melting zone of a blast furnace.

Boss—A circular bearing pierced with a hole for a shaft or pin.

Bottom Board—A flat board on which a bottom box is rammed over a pattern.

Bot Stick—The iron rod which holds a stopper of clay at one end for closing the mouth of the cupola, and has at the other a point for tapping.

Box Filling—The black sand of the floor as distinguished from facing sand.

Boxing-up—Making a large pattern to enclose hollow spaces, instead of using solid timber.

Brass—An alloy of copper, tin, and zinc variously proportioned.

Brass Melting Furnace—Generally an air furnace receiving crucibles. Sometimes a reverberatory furnace for large masses.

Brass Moulding—The moulding for brass castings, which differs in some particulars from iron moulding.

Bricking-up—The building-up of the skeletons of loam moulds with bricks.

Bricks—Common bricks, fire bricks, or loam bricks, used in loam moulding and in lining furnaces.

Bronze—A mixture of copper and tin variously proportioned, or with aluminium or phosphorus.

Building-up—Constructing patterns with segmental pieces to ensure permanence of form.

Burning-on—Casting new metal on old for the purpose of repairs.

Burnt Iron—Cast iron which has become largely reduced to the condition of an oxide, and rotten.

Burnt Sand—Sand which has been subjected to intense heat, so that it has no coherence. It is used for parting joints.

CAMBER—Curving of castings and of their patterns.

Carbon—The most essential controlling element in cast iron.

Carbon Cores—Hard, strong cores made of compressed carbon.

Carriage Ladle—A ladle mounted on a carriage.

Casting—The pouring or founding of the metal.

Casting Upright—Pouring a mould vertically with a view to secure soundness.

Cast Iron—An alloy of iron with carbon and other elements.

Cast Steel—Steel which has been melted and poured.

Centre Plates—Plates used for turning jointed patterns on, the plates being attached at the ends.

Centre Square—An instrument for finding the centre of a body without compasses.

Chalk—Used for whitening pattern-shop drawing-boards, and other purposes.

Chalk Line—A fine line chalked and strained tight, and snapped on a board to leave a straight chalk-mark for sawing by.

Chambered Core—A core enlarged about its central portion.

Changing Hook—A foundry crane hook with two bends for changing ladles of metal from one crane to another adjacent.

Chaplet—A metallic stud, or nail, or piece of hoop iron which affords support to a core independently of prints.

Chaplet Block—A block of wood which sometimes supports a chaplet nail.

Charcoal—Charcoal, when ground, is used for facing moulds.

Charge—The quantity of ore, fuel, and flux which is introduced into a cupola or blast furnace at one time.

Charging Door—The opening of a blast or reverberatory furnace through which the charges are introduced.

Check, or Register—The annular jointing between the top and bottom of loam moulds.

Chilling—Casting against cold iron.

Chord Pitch—The shortest distance between the adjacent centres of the teeth of wheels.

Chucking—Attaching work to lathe chucks.

Cinder Bed, or Coke Bed—A bed laid with cinders or coke at the bottom of a mould, into which the vents collect, and from which they are discharged.

Clay Plug—A plug of clay that closes an ingate until the basin is nearly filled.

Clay Wash—Clay diluted with water, and used for swabbing the bars of moulding boxes and lifters.

Clean Lift—A pattern delivery which does not damage the mould.

Clean Metal—Metal free from sponginess, scabs, and blow-holes.

Clearance—The space between adjacent gear-wheel teeth.

Coal Dust—Ground coal, to be mixed with sand for facings.

Coal Mill—A mill in which coal is ground into dust.

Coat—An application of loam, clay wash or wet blacking to a mould.

Cod—A mass of sand carried on a drawback, or other plate.

Cogs—The wooden teeth of mortice wheels.

Cog Wheel—A wheel with teeth of wood.

Coke—Used in cupolas and blast furnaces, and when ground, for mixing with facing sand.

Coke Baskets—Moulders' hand baskets.

Coke Bed—See *cinder bed*

Coke Mill—Same as *coal mill*

Cold Blast Iron—Iron smelted by cold blast.

Cold Shots—Small globules of cold iron enclosed in castings.

Cold Shuts—Lines of imperfect union in castings.

Collapsible Core Bar—A core bar which is made to fall inwards for ready removal, after the mould is poured.

Combined Carbon—Carbon in a condition of chemical combination with iron.

Contraction—The shrinkage of metal from the liquid state.

Contraction Rule—A rule longer than the common rule by the amount of contraction of iron, or brass.

Converter—The vessel in which Bessemer steel is made.

Cope—The top part of a loam mould.

Core—A central or internal body of sand.

Core Bar—A hollow bar on which cylindrical cores are swept up.

Core Board—A board cut to the profile of a core which is swept up against it.

Core Box—A framing within which a core is rammed.

Core Carriage—A carriage on which heavy cores are run into the stove.

Coring Up—Placing the cores in a mould.

Core Irons—Iron rods rammed in a core to afford a stiffening skeleton.

Core Oven, or Core Stove—An oven or stove in which cores are placed to be dried by heat.

Core Plate—A plate on which cores are swept up.

Core Print—A projection piece on a pattern, into the impression made by which a core is placed.

Core Ropes—Ropes or strings rammed in curved portions of a core, and withdrawn to leave vent holes.

Core Sands—Mixtures of strong sand.

Core Trestles—Trestles on which core boards and core bars are supported.

Crane—Used for lifting and turning over moulds and castings.

Crane Ladle—A heavy ladle which is slung and carried by a crane.

Cross—A double beam of the form of a St. Andrew's cross, suspended from a crane, and carrying suspension loops for moulders' work.

Crucible—Used in melting steel and copper alloys.

Crucible Cast Steel—Steel melted in a crucible.

Cupola—The furnace in which cast iron is remelted.

Cupola Hoist—A light hoist for lifting iron, coke, and limestone to the cupola platform.

Curving of Patterns—Patterns are curved in the opposite direction to that taken by their castings in cooling.

DAUBING—Lining a furnace or ladle with fire-clay.

Dead Head—A head of metal on a casting.

Dead Melting—Thorough melting.

Delivery—The withdrawal of a pattern from its mould.

Devil—An open cage in which a coke fire is lit for drying moulds.

Dog—A staple, or iron cramp.

Double Shrinkage—Two shrinkages must be allowed for when making patterns from which to cast patterns of metal.

Dowels—Pins uniting loose pieces temporarily.

Drag—The bottom box in moulding.

Draught—The taper of a pattern.

Draw—The same as *delivery*.

Drawback—A mass of sand carried on a plate, without a print.

Drawing Board—A board on which shop drawings are made to actual sizes.

Drop Bottom Cupola—A cupola in which the bottom is dropped to discharge the ashes.

Drop Print—A pocket print.

Dry Brush—A soft brush used for removing dust from moulds.

Drying—Driving off the moisture from moulds and cores by heat.

Drying Stove—A stove in which moulds and cores are dried.

Dry Sand—Strong sand, dried in the stove.

Dull Metal—Metal imperfectly melted.

EMERY WHEELS—Used for fettling castings.

FACE PLATE—A plate on which pattern work is turned.

Facing—A portion standing above the main surface of a pattern or casting.

Facing Sand—The sand which lies next a pattern.

False Core—The false core of a brass moulder corresponds generally with the drawback of the iron moulder.

Fan—A rotary machine for supplying blast to a cupola.

Feeder—A body of liquid metal which supplies shrinkage loss.

Feeding—Assisting the ingress of metal to the mould by the movement of a rod up and down in the runner.

Feeding Rod—A rod of ½ in. or more in diameter, used for feeding.

Fettling—Removing runners, fins, and other excrescences from castings.

Fillet—An angle, or hollow.

Fin—A thin expansion of metal spreading out from mould joint.

Flask—A moulding box.

Flat Rammer—A rammer having a flat end, used for finishing.

Floor Work—Moulding done by kneeling or bending over moulds on the floor.

Flow-off Gate—A riser gate.

Fluid Metal—Metal thoroughly melted.

Flux—Lime, which unites with earthy matter, etc., present in iron ore, forming slag.

Foundry—The building in which casting is done.

Foundry Crane—A triangular framed crane, having its top member horizontal.

Foundry Pig—Grey pig, fluid when melted.

Full—Slightly oversize.

Furnace Linings—Bricks of fire clay and ganister.

GAGGERS—Prods cast on loam plates.

Ganister—Silicious sand, and fire clay used in furnace linings and steel moulds.

Gas Coke—By-product of gas works, sometimes used in brass furnaces.

Gates—Ingates, or runners, through which metal enters a mould.

Grain—The texture of metal, or of wood.

Graphitic Carbon—Free carbon, present in grey cast iron.

Green Sand—Sand which is not dried.

Green Sand Moulding—Work done in green sand.

Grey Iron—An open grained iron, only moderately strong.

Grid—An iron frame on which a core or drawback is built.

Guide Iron—An iron curved to control the movements of a strickle.

Gun Metal—An alloy of copper and tin.

Gutters—Narrow channels cut in the joint faces of moulds for the escape of gas.

HALF PATTERN—One of the halves of a jointed and dowelled pattern.

Halving—A form of flat joint uniting pattern parts.

Handing—Making pattern parts right and left.

Hand Ladle—A small ladle carried by a single shank.

Hard Coke—Furnace coke, used in cupolas.

Hard Iron—Iron which is either highly silicious or chilled.

Hard Ramming—Ramming a mould hard, to prevent risk of lumps.

Hatching—Cutting up the surface of moulds with the trowel to assist the adherence of fresh sand for mending up.

Hay Bands—Used to bind the loam in swept-up cores.

Head Metal—A supplementary mass of metal on top of a casting, to secure soundness in the latter.

Hemp—Used instead of hay bands in small cores.

Hollows—Concave portions inserted in angles of patterns to ensure strength in the castings.

Honeycombing—A state of general sponginess in a casting.

Horse Manure—Used as a binding and venting material in strong sand.

Hot Blast—Employed generally instead of cold blast for smelting iron.

Hot Metal—Metal thoroughly melted.

Hot Sand—Sand from which recently poured castings have been removed.

INGOT—A mass of metal of rectangular section which has to be remelted for castings.

Iron—Foundry iron owes its virtue to the presence of carbon and other elements.

Iron Cement—A mixture used for joints and filling blow holes.

JAGGERS—The same as *gaggers*.

Joint—The parting of a pattern or of a mould.

Joint Board—A board on which a pattern is rammed.

LADLE—The vessel which receives molten iron from the cupola, and from which it is poured into moulds.

Lagging—Building up patterns with narrow strips of wood.

Lead—Used for lining up portions of patterns.

Leather—Used for the same purpose as lead, and for hollows.

Levelling—Necessary when work is moulded by bedding in the floor.

Lift—The act of withdrawing a pattern from the mould; or the character of the draw.

Liftering—Hanging and setting lifters in the sand of moulds.

Lifters—Hooks hung from the bars of boxes to assist in supporting the sand.

Lifting Plate—A plate attached to a pattern to receive lifting screws.

Lifting Screw—A screw with an eye used in withdrawing a pattern from the mould.

Lifting Strap—A piece of hoop iron attached to deep patterns for withdrawing them by.

Lime—A flux mixed with the charges of iron and coke in the cupola.

Lime Bag—A muslin bag from which lime is dusted over the joints of moulds, to show contact.

Loading—Weighting box parts previously to pouring.

Loam—A mixture of strong sands, rendered plastic with water.

Loam Board—A board by which a loam mould is swept up.

Loam Bricks—Bricks made of loam and dried.

Loam Cake—Pieces of dried loam.

Loam Mould—A mould made in loam.

Loam Pattern—A pattern made in loam instead of in wood.

Loam Plate—A plate on which a loam mould is built.

Loosening—Rapping a pattern.

Loose Pieces—Pieces which are not fastened permanently on a pattern body, but have to be left behind in the mould.

Lug—A projecting portion.

MACHINE MOULDED WHEELS—Toothed wheels made from sectional patterns in a machine.

Machine Moulding—Moulds in which some portions of the work are done by machine.

Malleable Cast Iron—Castings which are rendered malleable by decarbonisation or annealing.

Mending-up—Making damaged portions of moulds good.

Mending-up Piece—A piece used in mending-up, as a guide for finishing the sand outlines by.

Metal Patterns—Used when large numbers of similar pieces have to be cast.

Middle Part—The central portion of a moulding box having three or more parts.

Model—Sometimes applied to denote a pattern.

Mortice Wheel—A cog wheel, or one fitted with wooden cogs.

Mould—The structure into which metal is poured.

Moulding Box—The framework in which sand is rammed for moulds.

Moulding Machines—Machines used for producing moulds.

Moulding Tub—Used by brass founders as a receptacle for sand, and over which they work.

NAILING, NAILS—Embedded in weak portions of sand as supports.

OLD SAND—Sand which has been used continuously, and become weak.

Open Joints—Boards jointed side by side, but not in actual contact.
Open Sand Work—Moulds without a covering.
Oven Coke—Hard coke.

PAINTING—Denotes the application of wet blacking to moulds.
Paper Joint—In segmental and some other work, temporarily glued joints are made by the insertion of paper.
Parallel Print—Prints are parallel when they mould sideways.
Parallel Strips—Winding strips used for levelling mould faces and planing timber by.
Paring Tools—Long thin chisels and gouges.
Parting—The separation of the parts of a mould.
Parting Sand—Burnt sand used to prevent mould joints from sticking.
Pattern—A model from which an impression is taken in sand.
Pattern Register—A list of patterns kept in a book.
Pattern Stores—The building in which patterns are stored.
Peasemeal—A cementing material between the face of a mould and the blackening.
Peg and Cup Dowells—Brass dowells driven into the joints of patterns.
Pegging Rammer—A small rammer for small moulds and intricate portions.
Phosphor Bronze—Bronze to which a little phosphorus is added.
Phosphorus—An element which renders steel and cast iron brittle. A small quantity increases the fluidity of iron.
Picker—A pointed wire used for pulling small patterns from the mould.
Pickling—Removing the hard outer skin from castings by immersion in dilute sulphuric or nitric acid.
Pig Iron—The form in which iron is cast and sold for foundry use.
Pig-Iron Breaker—An appliance or a machine for breaking pig into short lengths for remelting.
Pine—Used more than any other material for foundry patterns.
Pipe Nails—Chaplet nails, used for supporting the cores of pipes.
Pitch—The distance between the centres of contiguous teeth in cog wheels.
Pitch Circle—The circle on which the pitch is struck.
Pitch Diameter—The diameter of a pitch circle.
Pit—A hole in which deep moulds are placed for casting.
Plaster of Paris—Used in making temporary patterns, and core boxes.
Plate Moulding—Moulding off patterns attached to jointing plates.
Platen—The table of a moulding machine.
Plumbago—Used for dusting moulds.
Pocket Print—A print which is continued above the position to be occupied by the core.
Pot Metal—A very common and cheap brass.
Pouring Basin—The depression into which metal is poured first before it enters the runners.
Print—A projection which makes an impression as a guide for the insertion of a core.
Prods—Jaggers or gaggers.
Pulling-up—The tearing-up and fracture of the sand in a mould.

QUICK—Denotes a curve of small radius.

RAMMER—A tool for consolidating sand round patterns.
Rapping—Loosening a pattern preparatory to its withdrawal.
Rapping Bar—A pointed iron bar used for rapping.
Rapping Hole—The hole in which a rapping bar is inserted.
Rapping Mallet—A wooden mallet used for rapping a pattern during its withdrawal.
Rapping Plate—A metal plate attached to a pattern to receive a rapping bar.
Receiver—A vessel which collects molten metal for pouring.
Reduction—The extraction of metals from their ores by heat and chemical affinities.
Remelting—Iron, and copper alloys are remelted to render them homogeneous and stronger.
Reverberatory Furnace—An arched furnace, with natural draught, used in some foundries.
Reverse Mould—A dummy mould of plaster upon which actual moulds are rammed.
Riddle—A coarse sieve.
Riser—An overflow exit from a mould.
Rodding—Laying rods in the sand of moulds to sustain it.
Rolling over—The same as *turning over*.
Rough Coat—A first coat of loam.
Rumble—A tumbling barrel.
Rumbling—Tumbling, or fettling in a rumble.
Runner—The channel through which metal enters a mould.
Runner Pin—A pattern for forming a runner.

SAFETY LADLE—A ladle tipped by means of toothed gears.
Saggers—The packing boxes used for annealing malleable cast iron work.
Sand—The matrix of foundry moulds.
Sand Bin—A receptacle for sand.
Sand Burning—Results from pouring hot iron against sand not protected with blackening.
Sand Joint—A moulder's joint.
Sand Mixer—A machine for mixing sands.
Sand Sifter—A machine for sifting sand.
Scab—An excrescence on a casting.
Scrap—Old metal.
Scrap Heap—A receptacle for scrap.
Scull—The scaly lining left in a ladle or furnace after use.
Segmental Work—Built-up pattern work.
Self Delivery—The delivery of a pattern having hollow portions instead of by coring.
Shank Ladle—A ladle having a handle or handles, to distinguish it from a *crane ladle*.
Shellac Varnish—The varnish used for the protection of patterns.
S Hooks—Lifters.
Shrinkage—Used in the same sense as *contraction*.
Sieve—Used for sifting sand.
Skewers—Used for holding pieces loosely to patterns.
Skimmer—A flat bar employed for baying back dirt fron the surface of metal being poured.
Skimming Chamber—A chamber in the course of a runner, designed to separate the dross, and prevent its entry to the mould.
Skin—The surface of a casting.
Skin Drying—Drying the surface only of a green sand mould.
Slag—A glassy substance produced by the union of earthy matters with calcium.
Slagging—Tapping out the slag.
Sleeking—Smoothing the surface of a mould with tools.
Slicking—The same as sleeking.
Slings—The loops which sustain moulding boxes from the cross
Soft Metal—Grey iron.
Soft Ramming—Easy ramming, which often produces lumps.
Splitting—Casting pulleys and wheels in halves.
Sponginess—Openness of texture in castings.
Spray—A series of runners arranged parallel or star-shaped.
Sprigging—Nailing.
Spring Chaplet—A chaplet formed by a loop of hoop iron.
Stakes—Bars or rods driven into the floor as guides to a top box.
Stays—Bars of moulding boxes.
Steady—An appliance used for encircling patterns of columns and pipes during turning to ensure steady running.
Stopping-off—Producing a shape in the mould different from that of the pattern.
Stopping-over—Filling up pocket prints.
Strickle—A profiled piece by which sand is scraped to any desired form.
Striking Bar—The bar to which a loam board is bolted.
Striking Board—The board by which loam, or green sand, is swept up.
Stripping Plate—A plate through which a pattern is drawn in delivery.
Strong Iron—Mottled iron, in which carbon is largely in a combined state.
Strong Sand—Sand containing loam and horse manure.
Sullage—The scoriæ of metal.
Sulky—A barrow ladle.
Sulphur—A very minute proportion of this element injures cast iron, rendering it white, and is objectionable in foundry coke.
Swab—A brush used for the laying-on of clay wash, or of wet blacking.
Swab Pot—The pot which contains clay water, or wet blacking
Sweep—A curved piece.

TACKLE—Lifting and hauling appliances.
Taper—The thinning or narrowing of patterns from above downwards.
Tap Hole—The hole from which molten metal is drawn.
Teeming—Pouring steel into moulds.
Thickness—A body of loam which represents thickness of metal.
Three-Part Box—A moulding box, comprising top, bottom, and middle.
Tile—The cover of a brass furnace.
Tinned Nails—Chaplet nails tinned to prevent rusting.
Tumbling Barrel, or Rumble—A revolving drum, in which castings are fettled.
Turning-over—Ramming the first part of a mould in the opposite position to which it has to be cast.
Turn-over Board—A board for ramming the bottom part of a mould on.
Tuyeres—The openings through which blast is directed into a blast furnace or a cupola.

VARNISH—Used for protection of patterns.
Venting—The formation of passages in moulds for the escape of gas.
Vent Wire—A rod by which vents are produced.

WASTER—A spoiled casting.
Water Bosh—A tank of water for foundry service.
Water Brush—A soft brush used for moistening the edges of moulds with water.
Weak Sand—Sand with little cohesion.
Wet Blacking—Plumbago in solution in water.
Wet Brush—A soft brush used for laying-on wet blacking.
White Iron—Iron which contains all its carbon in the combined state.
Winding Strips—Parallel strips.

YELLOW METAL—A soft variety of brass.

ZONES—The melting areas in cupolas.

ADAPTABILITY & WILL-POWER

Inimical Effects of Monotony in Life and Labour. Attributes of a Strong Character. Thought and Conduct. The Training of the Will

By HAROLD BEGBIE

NATURE abhors monotony. The force behind all material things never produces two leaves or two flowers of precisely identical condition; and if we believe with the younger school of physicists that the entire substantial globe is composed of only one material, we may see how wonderfully this force has laboured, and is still labouring, to produce infinite variety.

Variety is essential to life; monotony is inimical to life. In the case of humanity, variety in occupation is absolutely essential to vigour of mind, and we believe that many of the problems of the modern world are increasingly due to the present unscientific fashion of division of labour. The demand for an eight hours' day has certainly grown out of this division of labour, and is absolutely justified by the condition of the people. No man whose whole life is spent in manufacturing the heel of a boot or in watching the wheels of a single machine can possibly preserve vigour of mind and energy of body. All the other faculties with which he is endowed must of necessity perish under this insensate concentration, and with the atrophying of each faculty so precisely is he the less of a man.

Monotony of Occupation is Injurious. It has been truly and wittily said that an expert is one who knows nothing else. The object of existence is the perfecting of potentialities. If you have a man who might make a perfect boot, and you set him all day long to make only the heel, you infallibly destroy the object of his existence, and rob him of himself. He ceases to be what he is, and cannot be what he might become.

Lunacy, it has been said, is directly traceable to this monotony of employment. We believe that there are other causes for the alarming increase in lunacy statistics, and we are not disposed to argue that monotony of employment under modern conditions leads to absolute destruction of the reason. But we do not think that any physician will contest the point that this monotony of labour does most effectively destroy elasticity of mind and vigour of perception, qualities of the utmost value both to the State and to the individual. Dealing as we are with the individual, we base our conclusions on this contention—namely, that any specialising of study, employment, or recreation, tends to deprive the mind of elasticity and vigour.

The Foundation of Character. What are called the four Nelsonic attributes may be described as the foundation of character. These attributes are: (1) Self-reliance; (2) fertility of resource; (3) fearlessness of responsibility; and (4) power of initiative. Every one of these attributes, it will be seen, are connected with that intellectual adaptability of which we are writing. The intellectual man and the man of trade need for the success of their enterprises, just as much as the sailor for his, these attributes of individual power. There are moments when the scholar must be self-reliant, when the artificer must have fertility of resource, when the statesman must feel fearlessness of responsibility, and when the merchant must have power of initiative. These things are the fruit of education: and their destruction is the modern system of unscientific specialising.

Recreative Hobbies. Variety of occupation and variety of recreation, we have said, are the means whereby a man may enjoy intellectual adaptability. At present it is the custom of many workers to spend their free time in idleness, whereby we may see, in passing, how concentration of labour leads to the destruction of all healthful appetites. It should be the business of a man whose labour is monotonous to employ his spare time earnestly and energetically, whether it be in study or in games. This must be his first concern, the active occupation of his time. But after this the question presents itself as to the best studies and games for the purpose we are seeking—namely, intellectual adaptability.

There is great virtue in the hobby, and almost every man will find, if he examine himself, that he has in him an inclination towards some special undertaking. It may be carpentry, or gardening, or it may take the more intellectual form of some particular study, such as theology or history. Whatever it is, a man should cultivate it as well as he can, only using care to see that he does not make a monotony of his hobby. And concurrently with his hobby he must adopt some form of physical recreation which will bring into play the intellectual faculties of his mind. A good game is a game requiring some, if not all, of the Nelsonic attributes. No game is worth the playing which does not intensify consciousness and develop intellectual power. And no game, it may be said, can effect these results which is not in itself of an intensely recreative character.

Variety is Essential for the Brain. At present we inhabit a world in which a carpenter cannot whitewash a ceiling, and a house-painter cannot drive a nail into a wall. But these are not the men who force their way through circumstance to better fortune, and no man will perfectly enjoy life who is content to have his powers limited for him either by a trade society or by the conditions of his factory. It is essential to fortune, and it is essential to enjoyment of existence, that we should employ all our faculties, should struggle to exercise every side of our being. Of the greatest importance to the State is the problem of the present unscientific rule governing our factory population—a problem which will more and more press for solution; for the individual, with whom we are here concerned, the way to adaptability of intellect is less dark and troublous, is less difficult of discernment, and is so pleasant when once entered upon that we cannot doubt of its eventual discovery by the world. There is no reason in life why a man whose bread is earned by miserable and monotonous toil should not learn to re-create himself by the means so plentifully provided for him in these days, by music, literature, painting, and even travel. The brain requires almost constant employment in varied fields, and it is as necessary for the historian to know something of literature as it is for the engineer to know something of music. The more perfectly employed the brain—that is to say, the more every faculty of our being is developed and the more our consciousness is intensified—the easier will it be to concentrate our knowledge on any one directed end of our existence. It is largely, if not wholly, a question of our own will-power, which we may now consider.

Nobody doubts the efficacy of will-power. In a loose fashion all men hold that to have the will to do a thing is half the battle of the undertaking. When we enter a contest half-heartedly and dispiritedly we are said to be beaten before a blow has been struck. Our will determines for us beforehand the issues of our undertakings.

How to Improve Will-power. Now, there are many thousands of volumes expatiating on this agreeable subject, and, for the most part, they agree that the will can be educated and strengthened in a very marvellous fashion. But, until quite recently, the authors who concerned themselves with this subject did not get so far in their investigations as to say in what manner this education could be effected. To search those thousands of volumes is to come upon much curious speculation and no little degree of insight, but to come upon no definite instruction.

Of recent years, however, patient scholars have effected some kind of synthesis of all these generalisations, and the student is now in a position to consider the matter from a more or less practical standpoint. We are encouraged to believe by various experimenters that it is as possible to train the will-power as it is to master a sum in arithmetic or to construe a passage in Latin prose.

We do not attempt any definition of the term Will. That great mystery of our being must remain a problem for many centuries of time. Sufficient for our purpose, however, is the reader's concurrence in our postulate that every mortal possesses, in greater or less degree, a capacity for selection, or an inclination of desire, and that this capacity or inclination is, or should be, the express utterance of his personality. When a man says, "I mean to do this thing," he utters the strength of his will. When another man says, "I feel sure I shall fail in this matter," he confesses the weakness of his will.

We have now to see in what manner the will may be strengthened so as to lighten any given labour and, as it were, to guarantee the success of any given undertaking. It has been discovered by scientific hypnotists that an illiterate patient will remember, and know how to perform some difficult task given during hypnosis—*i.e.*, the state of trance—long after a return to normal consciousness. It has long been common knowledge among medical hypnotists that an idea implanted during hypnosis will present itself vividly and imperatively to the normal consciousness when hypnosis has passed. For instance, a patient told during hypnotic trance that in 32,364 seconds he shall fetch a particular book from the library, or give an order for hot water to a servant, will at the appointed time do exactly as he has promised to do in trance, without any conscious knowledge of the hypnotist's injunction.

Thought and Conduct. Mr. Charles Godfrey Leland, author of the "Breitmann Ballads," was the first man, so far as we know, to apply this common fact to the question of will-power. It had frequently been advised that a person with any difficult task to perform should "will" himself to the doing of it—that is to say, that he should repeat to himself his own assurance of success. It was a phrase of the period that a man might "hypnotise" himself into believing anything. People quite rightly held that repeated assurances of confident success would in no small measure assist the mind in nervous and critical junctures. Mr. Leland believed this, and recommended this casual form of auto-suggestion very successfully in America.

But it was the fact of hypnotism to which we have referred which first led Mr. Leland to what we may fairly describe as his "discovery." He saw that the mind during sleep was active, that it performed labour of which the normal consciousness was not aware, and that the ideas which it received in sleep were, for some unexplained reason, of a remarkable tenacity. He, therefore, made certain experiments, and in the end published a book announcing the facts of his discovery. The chief and essential fact of this discovery can be briefly stated: *A thought dwelt upon in the mind just before sleep will affect the conduct of the following day.*

For instance, Mr. Leland would go to sleep holding the thought that he might work all day on the morrow and experience no fatigue. On the morrow, although a very old man at this time, he would find a day's continuous work not only unfatiguing, but positively pleasurable. In other experiments he made himself immune from anxiety and worry, and ensured a calm optimism in the midst of troublous times.

The Power of Suggestion. Now, the value of these experiments is clear. Without subscribing to any of Mr. Leland's doctrines, we may see that auto-suggestion can be made to act during the unconsciousness of slumber.

Robert Louis Stevenson was wont to think over his plots at night, and then leave it to dreams to puzzle out the mystery. Cases of this kind are numerous. The consciousness acts during sleep, and with a very little investigation and effort it can be controlled and directed into determined channels.

It is, therefore, one of the best exercises for a man anxious to cultivate his will to think optimistically and courageously before he commits himself to slumber. Particularly is this so in the case of nervous disorders. A constant repetition to the brain that such and such a misgiving is delusion, will go a great way to strengthen the will to cast out "the demon." But for the general building up and fortifying of the character, it is the general attitude of courageous certainty which is required, and it is this thought which the consciousness should accustom itself to hold both night and day. There is no question in the world that auto-suggestion exercises a direct influence upon the mind, and to neglect it as an educating force is to miss one of the most certain weapons put into the student's hands.

Master the Machinery of the Brain. There are other and minor exercises for educating the will-power, all of them useful and worthy of practice. It is a curious fact that loquacious people are almost invariably weak-willed, and that excitable and sensitive people are almost always inexact and inaccurate in their statements. It is, therefore, a wise exercise to restrain the desire to overtalk, and it is a most helpful exercise, when talking has to be done, to study to express oneself in precise, definite, and brief terms. These are, however, among the minor exercises of this matter, and considerations of a like character will suggest themselves to anyone who gives the subject his attention.

The chief end in view is to obtain perfect mastery over the machinery of the brain, to be absolute captain in one's own castle. That few men enjoy this mastery is a well-ascertained fact. The easy definitions of the theologians concerning "free will" are unhappily of no value, because they leave humanity out of their reckoning. Every physician can narrate a hundred instances in his own experience of people "sinning against their will"; of people who come with tears in their eyes, begging for deliverance from the tyranny of some dreadful and hated vice.

Free Will. Few men enjoy free will. The perfect man—free to rise, free to fall, and master of all the impulses of his being—is as rare as December's rose. But that every man may—*with training*—exercise some control over his being is, we believe, an established fact; and that every man, carrying out this training of the will-power, will enjoy an enormous advantage over the man who accepts the will which Fate has brought him, as he accepts the colour of his hair or the shape of his finger-nails, is, we are convinced—the universal faith of another generation.

The reader, if he thinks about the matter, will perceive how this reasonable and mysterious power of auto-suggestion is the real secret of all the mystery and pother which has been made about mental-healing, faith-cures, and "Christian Science."

These people merely carry to extravagant ends a fact of which every physiologist has long been aware. The will can be educated to cast off certain diseases, and in all cases to assist the physician. Therefore, when the "Christian Scientist" tells a patient not to believe that he has a headache, or a cancer, but to concentrate all his thoughts on the universal benevolence of the Omnipotent and All-Perfect Creator of the Universe, he does but counsel him to practise a little auto-suggestion for the relief of his sufferings. And as faith is of the utmost importance in this matter, it is manifest that he who believes, from religious motives, that he has no headache is more likely to influence his consciousness than he who does so only because a doctor advises it.

The Power of the Trained Will. Gradually, however, it will be perceived that the explanation of the matter is purely physiological. A thought entering the mind operates upon the general tendency of the personality either for good or ill. For instance, a nervous person believing that he is going to stammer over a word will almost infallibly do so, while a vigorous and healthy cricketer, going to the wicket with the conviction that he will make a great many runs, is almost sure to puzzle the bowlers and delay his return to the pavilion.

These things being certain, it is eminently advisable for a man to educate his will-power in a general, rather than in a particular fashion. For instance, a man beset with a particular vice should abandon all attempt to think himself out of it, and endeavour as best he may to think himself into better and more delightful tastes. The will, in other words, is always open to flattery. If the ballad-monger tells himself for a considerable time that he is the equal of Shakespeare, he may in the end succeed in writing finer lines than Martin Tupper, though at the outset he was Martin Tupper's manifest inferior.

The Value of Counter Attractions. The education of the will, we must remember, is not a matter of effort, but the result of a habit. To concentrate the thought upon bright and cheerful images is the best way of getting rid of repulsive images; but before the will can exorcise those undesirables it is first essential that it should have acquired at least an interest in the bright and cheerful images. A man striving to develop in himself a taste for art in order to save himself from the inclination to over-drinking must first have read some simple and informing manual of art before he begins to call up to his consciousness the beautiful and glowing images of the painter.

First, a taste for, or, at any rate, some knowledge of, a particular subject, then self-hypnotism to the end of victory, and the will, trained to be powerful in this particular field, will be found to have strength and vigour in all the other enterprises to which its owner commits it.

"MATTER IS ELECTRICITY"

The Ultimate in Chemistry. Properties of Electrons. The Beginning of all Things. Science Tending towards Philosophy. · The Impossibility of Positive Dogma

By Dr. C. W. SALEEBY

SO much for the fate of the electron. Let us now see whether there is anything that can be added to our knowledge of its actual properties. It is known that the course of electrons produced under certain conditions may be influenced by the approach of a magnet. They are deflected, and this deflection can positively be seen by suitable illumination of the experiment. It is by means of this knowledge that we are able to ascertain certain properties of electrons. We are enabled to ascertain, for instance, their velocity. This varies with certain conditions. It was quite lately stated that these electrons move at a speed resembling that of light. In point of fact, they do not move so fast as light. Nevertheless, the speed of light is the only one with which that of electrons can be compared. There is no material body, whether an atom or a star, that has a speed in any way comparable to that of electrons. We may say that 10,000 to 100,000 miles per second about represents the limits, so far observed, of their speed.

The Mass of Electrons. But a still more interesting question is that to which M. Poincaré alluded in the quotation on page 2395. What is the ratio of the electrical charge of the corpuscle to its mass, it having been noted already that this relation is constant for all corpuscles, from whatever " element " they may be obtained ? It has been hinted that physicists seem steadily to be approaching the conclusion that the electrical charge of the corpuscle accounts for all its mass. It is just a quarter of a century since Professor J. J. Thomson first enunciated the remarkable idea that the inertia of matter is electrical. The considerations he advanced dealt with imaginary bodies, which were extremely small, and which moved at speeds comparable to that of light. Little was it then thought, except perhaps by Professor Thomson himself, that the existence of bodies having these properties would one day be demonstrated ! When electrons were discovered the question arose whether their actual properties showed correspondence with Thomson's mathematical reasoning, and especially with his doctrine that the mass, or, rather, the inertia, of a body increases with its velocity. The assertion of Professor Thomson was that an electrical charge upon a moving body possesses inertia, due to the electromagnetic disturbance which it creates in the ether through which it passes. As its speed increases its inertia increases, and therefore its apparent mass. It has now been conclusively demonstrated, in the case of corpuscles, that their mass increases with their velocity, in accordance with the teaching of Thomson.

The Last Analysis of Matter. But this is the least important result of this inquiry, for Professor Thomson next proceeded to compare the experimental results with the results which should theoretically be obtained if we make the remarkable assumption that the electrical charge of the corpuscle can account for the whole of its mass, leaving not even what M. Poincaré calls " a little, a very little matter." Professor Thomson found that the two sets of results are in such close agreement that the minute differences between them may readily be disposed of as within the limits of experimental error. The conclusion is, then, that the whole mass of an electron is electrical—that is to say, is due to the inertia of its charge. Thus Professor Duncan emphatically says: "On this view, then, the to-and-fro motion of a pendulum and the electrical oscillations of the spark from a Leyden jar are simply two manifestations of an identical thing—the inertia of a charged body." Here, then, we have the root question of chemistry apparently answered in a phrase. " All mass is the mass of the ether; all momentum, whether electrical or mechanical, the momentum of the ether; and all kinetic energy, the kinetic energy of the ether."

In other words, in the last analysis, matter is electricity.

But there is another question which the reader will not permit us to neglect. When attempting to describe the corpuscular theory of matter, so far as it is at present formed, we declared that the electrons of the atom, being all negatively charged, tend to repel one another. They are bound together within the atomic whole by means of positive electricity. We have to conceive of the " foundation " of the atom as probably a sphere of positive electrification.

What is Electricity ? We have not completely described the new theory of matter until we have answered, or, at any rate, raised, certain questions about this positive electricity. Where does it come from ? What becomes of it when the atom disintegrates ? And in what does it subsist ? Even if there be no material basis for the electron, may there not be a material basis or foundation for this sphere of positive electrification ?

Now, it so happens that we are unable to answer these questions. The nature of positive electricity is almost incomprehensible—at any rate, it is not yet comprehended. Perhaps positive electricity consists of particles, just as negative electricity does ; that would seem probable. Yet, if it does, certain difficulties arise. For we seem to be able to explain the mass of an atom as the sum of the masses of its negative electrons. Hence it would seem that if there be particles of positive electricity they either have no mass at all or else their mass is so small as to be practically negligible. We do not seem to be able to answer these questions at present because we cannot, so to speak, "get at" positive electricity. It is not shot forth from atoms as negative electricity is, and it seems to exist nowhere except as parts of atoms. The question of the nature of positive electricity is of supreme importance.

Did the World Ever "Begin"? In a recent lecture Professor Thomson stated that our ignorance in this respect prevents us from determining the nature of the direction of natural changes. It seems that our ignorance of the properties of positive electricity—as to whether it is compressible or not—leaves it uncertain whether "the universe began as a simple collection of homogeneous atoms, and is evolving into a complex thing which will ultimately become one huge atom, or whether it began as a complex huge atom and is now breaking down into simpler, smaller and similar atoms." The question in brief is whether the process now seen is the upward or the downward phase of evolution. Surely this tremendous alternative will impress the reader with the importance of the great gap in our knowledge for which this apparently satisfactory phrase, "positive electricity," really stands.

One comment, however, falls to be made upon Professor Thomson's words, or, rather, his use of the word "began." We must ask him by what right he assumes any beginning. We must ask him whether he is quite sure that he can really form the conception that the universe *ever* "began." For convenience, no doubt, the physicist is justified in using such a terminology as this; but before we can accept it in the stupendousness of its full meaning we must invoke the judgment of the higher studies—psychology and philosophy itself—in order to decide whether the idea of a beginning in the old-fashioned sense of "creation" can really be credited: whether we must not rather conceive of the Eternal Power that is behind the universe not as having called it into being at a particular time—our very idea of time being merely derived from our observation of material changes in the universe—but as underlying, maintaining, and sustaining it from eternity to eternity.

The Supreme Importance of the New Chemistry. Here, at any rate, we must close our long discussion of the new chemistry, of the possibility of which only the few dreamed ten years ago. It is a chemistry which is of no practical importance whatever at the moment to the practical man; it does not affect the price of sodium carbonate or coal gas, but *it deals with the fundamentals*, and we may be absolutely certain that our knowledge of fundamentals will ultimately prove to be of the utmost practical value. The hint has already been given as to how the new chemistry may lead us to the utilisation of energies beside which all the sources of energy that have hitherto been employed for human purposes are trivial.

But, while the practical importance of the new chemistry is only on the horizon, its theoretical importance is present, and is almost overwhelming. We have failed in our task if that has not been already made evident. A few stray sentences here and there will, we hope, have suggested to the reader that the theoretical significance of these extraordinary studies is not only scientific; they deeply concern philosophy as well. There is no more important question in philosophy than the nature of matter, and now that question has been answered. Again, among the supreme questions of philosophy are those which relate to the past and the destiny of the universe. These questions will ultimately be solved with the aid of the knowledge of fundamentals which men have gained during the past year or two. Again, philosophy is concerned to know whether all the diversities of the world can be resolved into a single substance. That is one of her supreme questions.

The Ultimate of Matter. Here, again, the new chemistry is of an importance which we cannot overestimate. Not only has it made the notion of 75 or 80 indestructible elements of matter seem to belong to an almost prehistoric order of thought; not only has it found the common element of all these elements; it has done much more. It would have been a great achievement even to show that, to quote Tennyson, there is "one element"—that in the last analysis all kinds of matter are one; but the new chemistry has done far more than this.

It has not merely shown us that atoms, though chemical ultimates, are not absolute ultimates, but it has shown that the apparent ultimate of which all atoms whatsoever are composed, the very ultimate of matter, is *in its turn* not an absolute ultimate. It is no more an absolute ultimate than the atom is. The new chemistry teaches us that the ultimate of matter is, in its turn, merely a particular variety or aspect of energy. If we attempted to state a category of the cosmos, writing down a list of the various things it consists of, we might graphically learn the significance of the new chemistry by comparing the length of such a list made ten years ago with the list that we may make to-day. The 75 or 80 chemical elements would have had a place in the old list. A little later their place would have been taken by the simple word "matter," it having by then been recognised that all matter is one. But now even that word would not appear, it having now come to be recognised that matter is merely an electrical phenomenon. How much further the new chemistry leads us towards an objective, scientific, matter-of-fact proof of the philosophical belief that all things are one we cannot here pause to say.

Science and Philosophy. Surely, at any rate, we have said enough to convince the reader of the overwhelming importance of these scientific facts to the philosopher, who has no interest in the details of science for their own sake but cares for them merely in so far as they may serve to aid him in his attempt to answer the question of philosophy.

But, at any rate, we must here insist upon a profoundly important truth. It is that, as science advances, it constantly leads up to philosophy; again and again the historian of scientific thought finds himself led beyond his proper province into that of philosophy. Certain types of scientific mind resent any connection between the two studies. They regard any attempt to speculate or to recognise the ultimate importance of scientific facts as unscientific. On the other hand, certain types of philosophic mind, such, for instance, as the mind of Hegel, resent deeply the intrusion of science into philosophic questions. These philosophers regard science as beneath their notice, just as the scientists to whom we have alluded regard philosophy as merely a vain kind of word juggling or else a species of poetry, except that, unlike poetry, it is not beautiful.

Nature is Orderly and Intelligible. But we should be able to avoid both of these extremely common and extremely pernicious errors. It is perhaps the most distinguishing mark of the purely scientific thought of the nineteenth century to lead up to philosophical problems. If that generalisation, which has been clearly stated by Dr. Merz, the great student of nineteenth-century thought, be true of the nineteenth century, it is more and more abundantly true of the scientific thought of the twentieth century, the achievements of which are already equal to those of half a dozen centuries in time past.

Among the great truths which the new chemistry serves to strengthen is, first of all, the truth that Nature is orderly; and secondly, that she is intelligible. The idea of the universal range of law is more or less clearly before the minds of all of us. Yet, imperfect instruments as our minds are, we constantly find ourselves confronted by facts in Nature which seem to have no reason or sense in them. They seem quite arbitrary; they simply are so and we have to accept them. Closer study invariably shows and will continue more abundantly to show, nevertheless, that there are no arbitrary facts in the Cosmos. What could be less intelligible or rational, less reasonable, more arbitrary, than the existence of some seventy-five or eighty elements into which all matter could be resolved, but which were incapable of being any further resolved? But the new chemistry has shown us that the existence of these elements and their relations to one another, their history and destiny, are capable of an absolutely rational interpretation. Even in all the multitudinous facts of chemistry, which it might be thought that no one could predict, we find causation and continuity to be absolute and the arbitrary to be non-existent.

Dogmatism is Impossible. There are many types of mind. Some readers will be annoyed at the recent sections of this course on the ground that they are not sufficiently prim, exact, and dogmatic. Other readers may be annoyed on the ground that we have made too great deductions from data that were not sufficiently secure. But, at any rate, we have done our best. It must be most emphatically pointed out, however, that the reader must read these sections with caution and reserve, not too hastily accepting any statements. Their value will lie, if they have any at all, far more in their power to stimulate and interest the reader's mind, so that he will closely follow for himself the great developments of the new chemistry, than in the actual setting forth of alleged facts. We cannot confidently say that any of the more precise details of the new chemistry are finally fixed. It is literally true to say that new developments arise every week, and that part of what was written in March comes to wear an antiquated look in April. Only those who live in the midst of it can realise the almost electronic speed with which our knowledge of these questions advances. One or two instances will be instructive, especially if they serve to show the reader that he must on no account consider his knowledge of the subject to be adequate when he has studied the preceding sections.

The Rapid Growth of Knowledge. For instance, what was said earlier in this course regarding the emanation of radium cannot now be regarded as an adequate statement of the facts. The reader must not imagine that the emanation consists entirely of immature atoms of helium. That seemed to be the probable interpretation until quite recently; but now it is necessary to recognise the further details which will be found stated above. Again, only a few lines later, we referred to the evolution of radium from uranium. That evolution has been suspected for some years, uranium having, as the reader will remember, an atomic weight of 240, while that of radium is 225. But it was very difficult to prove, and for some time the absence of any positive evidence seemed to tell against this view. Now, however, it may be taken as the fact. To some readers the question will occur—Does uranium produce an emanation, and is radium its product? Now this is a fair question, but, as far as we can judge at present, it seems to be true that uranium *produces no emanation whatever.*

Radium and the Sun. Again, in discussing the presence of radium in the sun, we insisted on the profound alteration that its presence there—which is extremely probable—must cause in our estimate of the cosmical time-table. Fully recognising the importance of the principle which Lord Kelvin called the dissipation of energy [see PHYSICS], we ask ourselves as to various sources from which energy, available for human life, may still be expected. First in the history of our knowledge comes, of course, the gravitational shrinkage of the sun as considered by Helmholtz; secondly comes the (extremely probable) presence of radium in the sun; thirdly comes the discovery of untold stores of energy in every atom of the sun and every atom of the earth—energies so abundant that all the extra-atomic energies with which we are acquainted, put together, count for nothing beside them. Thus, even if there be no radium in the sun, there remains more than a possibility of one day tapping the intra-atomic energies and extending the life of man, who has behind him merely a brief history of a quarter of a million years, through æons and æons, inconceivably long and inconceivably numerous.

We must devote one line to reminding the reader that there is doubtless another sort of rays, called the *Delta* rays, to be added to the Alpha, Beta, and Gamma rays, already described on page 2028.

In the same section, and on the following page, it is necessary somewhat to re-read the paragraph in which an atom is compared to a solar system. There we spoke of the electrons as "constantly colliding with one another in their mad race within the atom," the result of these collisions being to expel some of them from the atomic system. Here we must remind the reader that the corpuscular theory of matter in its latest form enables us to advance very definitely beyond such a statement of the facts as we have quoted. In speaking of collisions we are using only a metaphor, and not a very good metaphor at that. We should remember how far apart the electrons are from each other, relatively to their size.

Expulsion of Electrons from Atoms. Furthermore, Professor Thomson has now provided us with a theory which makes the expulsion of the electrons from the unstable atom quite intelligible without our having to invoke any idea of collisions at all. We now believe that the electrons, or Beta rays, are expelled in virtue of the sudden transformation of a portion of the potential energy of the atom into kinetic energy, or energy of motion, which expresses itself by its power to carry some of the electrons out from the atom at the tremendous speeds we have described.

Recognising the law of the conservation of energy, we see, of course, that the new type of atom thus suddenly formed not only has fewer electrons but also contains less energy. Lastly, we observe that the moment of expulsion, though it does not depend upon a collision, is yet determined by something equally sudden, notwithstanding the fact that it indicates merely a point in the steady and agelong radiation of energy from the atom. At last a critical point is reached and the result is as sudden a cataclysm as if there had indeed been a collision.

Following our review of the preceding sections, it may be noted that Mr. Butler Burke has now published the remarkable book in which he discusses the relations of radium, or rather the phenomena of radio-activity, to the facts of life and living matter. If space availed, we might add almost indefinitely to what has already been said on this subject. At any rate, it may be noted that the reading of Mr. Burke's book cannot fail to increase the amount of attention which anyone may have previously devoted to his work [see "The Origin of Life." J. Butler Burke. Chapman & Hall].

Nature Makes No "Leaps." Yet another point, which seems to demand more insistence than has yet been devoted to it, is this—that the processes of atomic evolution are not discontinuous and sudden. The old doctrine seems to be as true of the evolution of the atom as Darwin showed it to be true, or almost entirely true, of the evolution of living things: *Natura nihil facit per saltum*—Nature does nothing by leaps. The processes of atomic change are absolutely ceaseless and continuous. It is only the consequences of these changes that suddenly become conspicuous when the atom becomes unstable. But the new and stable atom which is then formed itself proceeds to undergo continuous change. The evolutionary doctrine is true here as everywhere else. "Nothing is constant but change." For practical purposes we may assume that atoms are stable, but the most stable of them is steadily journeying, even though the journey may take ages, towards instability. Spencer's law of universal rhythm is thus illustrated here also, and, as a distinguished lady has said, "what is just upon its flight of farewell is already on its long path of return." Our attention is directed to certain striking moments in a continuous process, but we must not forget that it *is* continuous. Here, of course, is another illustration of that supreme generalisation which we express as the *continuity of Nature*.

"The Chemistry of the Carbon Compounds." And now we must pass, though very reluctantly, from our all too brief consideration of our subject, our knowledge of which will be recognised in time to come as constituting a great epoch in the history of the human mind; a subject which no one would now hesitate to regard as epoch-making, if only it were a few centuries old. We must pass to a new division of the subject, though in doing so we must again remind ourselves that all our divisions are, at bottom, artificial, and that there are not two chemistries but one chemistry. We are about to pass to what, not so long ago, was called organic chemistry. By this was meant the chemistry of those bodies which are characteristic of living things. It is quite distinct from what is now known as physiological chemistry—the study of the chemical processes which occur within the living body and play such an essential part in its life. But it has already been pointed out that the old division of chemistry into inorganic and organic is untenable, and in the next place we must devote ourselves to a brief study of the principles of what we prefer to call the *chemistry of the carbon compounds*, and of the reasons which render the use of that term desirable.

DESIGN OF VEHICLES

Principles of Vehicle Design. Space Requirements in Vehicles for Road and Rail. Influencing Factors in Vehicle Construction

By H. J. BUTLER

Railways. The road-coach design having been discarded, it was found that the girder frames on which the bodies of railway carriages were at first mounted might be used to greater advantage. The designer had not to consider any great display in external appearance, for the vehicle runs on a private highway, and is essentially a travelling carriage, not a pleasure carriage to be shown off in its beauty of outline in the park or fashionable thoroughfare. So curved lines have for the greater part been discarded, being retained in the rounding of window corners, the tops of doors, the roof lines and the turn-under sweeps. Even these small embellishments are done away with, especially in American practice, excepting the necessary rise in the roof.

The rectangular is the general type of railway carriage now prevailing both for passenger and goods stock. It is reversible, so that it fulfils its object in either direction without the need of a turntable [1, page 2462].

In the early days of evolution we see the dimensions of the road-coach retained in some degree. Roof rails for carrying the luggage, with a protecting tarpaulin and the brakesman's seat were remnants of road-coach design.

Need for Enclosed Bodies. Travelling at a good speed, we need continual protection from the weather be it wet or fine, and from the smuts and steam from the engine. Therefore, no open or convertible close-to-open vehicle is suitable, and the open-truck type soon died out, albeit after plenty of comment. How to construct a closed carriage with efficient ventilation is still, perhaps, unsolved.

The over-all width and height of a railway vehicle is governed in the first place by the loading gauge. All railways do not show uniformity in the height and width of tunnels, and different countries have their respective standards. The height of platform, the width between the up and down line, and radii of curves, are all important factors that must be considered.

As previously suggested, the introduction of the bogie at once made the use of a longer vehicle possible. Two four-wheeled bogies are now extensively used on passenger and freight types all over the world. Two six-wheeled bogies form a very easy running gear, and they may be seen on dining-cars and other stock.

Leg Room. The distance from the top of the seat-board to the floor, measured vertically as well as diagonally to the foot resting-place, should be about 15 in. in the first and 24 in. in the second instance. Having a flat floor, railway travelling is often found tiring from this special standpoint, more so than riding in a brougham, canoe landau, or other road carriage where the bottom is rounded, or the juxtaposition of the parts allows the feet to rest at an easier angle with the lower leg than is the case where an obtuse angle tends to be formed.

Knee Room. Knee room is often provided in proportion to the class of carriage. Main-line types are generally more comfortable in this direction than suburban types, although the gangway is more used in the latter. From 24 in. to 28 in. is an average distance measured horizontally between the opposite seat edges; but we see as much as 4 ft. in some new electric trains. Not only have we to provide for two sets of knees, but some allowance must be made for a gangway. Should one be travelling in a compartment carriage on the London Underground when it is crowded, the difference in knee room, especially in the later types, where the seats are set a little farther back than usual, will be recognised at once. But we cannot have more knee room in compartment types without longer bodies. Longer carriages mean longer trains, which again mean longer platforms. Even a couple of inches in a compartment would lengthen a train of ordinary length some 10 ft. besides adding to the expense of construction.

Head Room. Head room must be sufficient to allow a man to stand erect with his hat on. A traveller does not usually gain his seat immediately on entering, as he does in a good many types of road vehicles, and to maintain a crouched position for any number of paces, however few, is most uncomfortable. A height of 7 ft. 1½ in. from the floor to underneath the hoop-stick, or inside of roof, is an average for a central measurement when the arc of the roof is at its highest. Where a side corridor is used we have a similar measurement at that portion of the vehicle, and when a clerestory is used as an additional ventilating area, the depth of the same is added to the height, making about 8 ft. 6 in. over-all. As this head room is needed only in the gangway, the space left above the head of the seated passenger can be utilised to accommodate luggage racks for small articles.

The height of goods vehicles of the open type is sometimes decided by the merchandise carried. In the conveyance of commodities of light bulk it is important to pack in as few trucks as possible. Hay and straw are loaded well up to the limit. In conveying a tramcar of double-deck variety by rail the roof work has to be dismantled, and the special trucks now built are of the well type. The breakdown cranes of a railway have to be designed so as to lower down within the loading gauge when travelling. But special commercial items such as theatrical scenery, girders, heavy ordnance, boilers, rails, boats, etc., demand a long vehicle, perhaps the longest being one used in connection with the Bethlehem Steel Works, United States of America, and measuring about 100 ft.

Length and Width of Seat. This detail, like knee room, is very often a matter of the fare paid. Anything less than 16 in. is undesirable, but generally 17 in. or 18 in. is allowed even in third-class suburban coaches. English people are familiar with the "To seat five persons" legend, and know what it means when one of those five is of Falstaffian proportions. The Great Eastern Railway and other companies have managed to get six a side by increasing the width of the carriage to a smaller clearance within the loading gauge, and here one sees the greatest number of persons carried in the smallest possible length of train. It may be interesting to note that the company mentioned hit upon the novel idea of converting the old stock to accommodate the extra passenger a-side.

The *corridor carriage* does not have a large carrying capacity. The gangway from end to end takes away much of the seating room, while kitchens, serving compartments, and lavatories curtail space still more, and one finds a larger tare weight of carriage per passenger than in the old type.

The Compartment Carriage. Americans often wonder how we can tolerate the side-entry compartment, which is looked upon as a relic of the mail-coach days, when we also have the corridor with its end doors. Besides giving a greater seating capacity in a given area, the familiar English type allows of a quicker emptying of the train at the termini, and at the intermediate stations the traveller may get in or out with a minimum of trouble. Those who travel by the London "Tube" know that they have to walk quickly to get out to the platform, in order that the quick working of the trains may be maintained. This business of hustle, the platform gates, the arrangement of the seats, the shouting of station names, is taken from the Manhattan Elevated Railway of New York. In the Great Northern and City Company's trains we see an extra side door situated in the centre to expedite the exit of the passengers at busy times. Emptying the train at a terminal station is, however, not so important as emptying the platform, which is a matter of consequence where fully-laden trains are constantly arriving at certain periods of the day.

Merits of Different Types. It may, therefore, be seen that the side-door type has its advantages as an economical and effective suburban carriage, and it may yet be seen for some years, especially in a conservative community such as ours. The coming of the "tubes," and the adoption of electrically-propelled trains, which are generally of the corridor type, will no doubt all help to discourage the compartment variety of rolling-stock. If we build corridor carriages, let us carry out the idea properly by connecting up the coaches with vestibules in order that a free passage from end to end may be enjoyed. Should the corridor be in the centre or at the left or right-hand side, it is of the utmost importance that the connecting vestibule be in one standard position, so that coaches of different companies may be made up into one properly working train. As the presence of curves on the permanent way necessitates a flexible vestibule, so one placed in the centre will undergo less wear and tear than a side one. Thus, the adoption of a central vestibule is a development that may be expected.

Under-frames. We have seen how the different dimensions lend comfort to the passenger, and the relative values of the different types in producing the result desired. Besides all this, a knowledge of the strength of materials is absolutely necessary in designing the under-frames, especially those of the long, bogie types. This is a detail that has to be carefully considered after the rough, or block plan has been passed by the traffic superintendent. Moreover, the different pillars and rails must be of sufficient strength to withstand the special stresses put upon them, and the construction should be as simple, economical, and light as possible, consistent with strength, and should be put together so as to allow of being easily repaired when occasion demands. It is also important that a safe and easy access be provided between the platform and the carriage.

Tramcars. Tramcars [3, page 2463] usually take a very useful strip out of the centres of our main roads, and even if only public opinion has to be considered, it follows that they should take up as little of the highway as possible.

It will be readily calculated that if we are to have a useful tramcar we cannot do with much less width than 6 ft. over-all for a 3-ft. 6-in. gauge, and 7 ft. in large cars, running on the standard track. Still, this added to the minimum of 15 in., allowed by the Board of Trade between two passing trams, means from 13 ft. to 15 ft. of roadway given up to this form of traction.

In double-deck trams we find that bridges seriously interfere with the height of the vehicle, and often the permanent way has to be lowered to give the necessary clearance. The length of car, type, and seating capacity is largely a matter of local conditions. In America we find the single-deck type favoured; here the double-deck is found in greater numbers. We have four-wheeled and bogie types, as in railway stock; and here again length is made subservient to the type of mounting. As the rails keep a tramcar in the middle of the highway, suitable means must be adopted to allow of easy mounting from the surface of the roadway. In reckoning knee room, we must not forget to give a comfortable distance between the backs of the garden seats, and as a car is a reversible vehicle, these seats must be provided with swinging backs. A tramcar must be capable of being driven and conducted from either end, be it mechanically propelled or of the old horse-drawn pattern.

Motor-cars. The motor-car is generally a petrol or steam vehicle built on a girder frame, which corresponds very much to the patterns already mentioned. Pressed steel frames for railway goods waggons and automobiles are often made by the same firm. Given a safe clearance from the ground to the bottom of the crank chamber, the designer is wise to get his vehicle as low to the ground as possible ; 24 in. to the top of the frame compares very much in the favour of this type of locomotion when the same distance is considered in some patterns of the old horse-drawn carriage. The Mercèdes car of to-day is easy to get into, apart from any mechanical considerations. As suitable means of giving a motor-car a full lock have not yet been discovered, we must hesitate before adding greatly to the *length*, and therefore the width of road required for turning. The Ackermann type of pivoted axle arm, however much the frame may be recessed, allows of only a partial lock, and those who have designed public service cabs find that the Metropolitan Police do not approve of the room required to reverse some of these vehicles. Ladies with fine dresses do not like to enter a car from the back or going through a series of gymnastics to pass through any patent front entry. Therefore the side entry has an initial advantage in its convenience, and when it is remembered the private travelling public have been used to it for generations in the usual type of road carriage it will be realised that it has a great hold.

Leg Room. The leg room is decided by the engineer, who plans the relation of the pedals, the steering wheel, and the column according to his own idea. One sees now and then a luxuriously padded back, which the driver can never use, as he is forced to sit on the edge of the seat to reach the pedals, but this is seen less frequently than formerly.

Leg, knee, head, and seat room, however, must be as limited as possible consistent with comfort. One cannot expect to stand erect in a motor-car, although in the long types, with side entrance and cape head, a passenger of medium height can often stand upright. Likewise in the hind part of these side-entrance vehicles there is often more than enough leg and knee room.

For ordinary normal types 15 in. vertical and 22 in. to 24 in. diagonal leg room is provided. Knee room between vis-à-vis seats in broughams, landaulettes and similar types is about 19 in. or 20 in., while head room is curtailed from 40 in. to 44 in. from the seat board to under the cant rail, this being increased to 48 in. and over in types where one has to step a few paces before gaining the seat. Width and depth of seat, especially in the better classes of vehicles, is quite as generous as one could wish, 42 in. to 44 in. between the pillars for two persons at once being an apparently comfortable measurement. On front inside seats this measurement is lessened, but the chauffeur generally has occasion to complain of want of width rather than of length of seat.

By adopting more or less minimum sizes we are not building a vehicle which will cause great demand on the horse-power provided. Moreover, neatness, cost of production, and garage room, will not be unduly sacrificed.

Width. Width remains about the same as in the usual coachbuilders' productions. Width of châssis is a great point to the body-builder, especially if he has to construct a 48-in. body (three sitting abreast) between the standing pillars on a châssis some 865 mm. (34$\frac{1}{16}$ in.) wide.

Châssis Dimensions in Relation to Motor Body Sizes. There are many types of châssis, and each year these are being altered in length, width, and position of wheels. Therefore the coachbuilder finds his working drawings become almost useless owing to this continual change. The side entrance requires that we must look for the position of the hind wheel in relation to the dashboard and the height of the frame. Although a 21-in. door is the least possible dimension for comfortable entry, we often find expensive châssis being constructed without due regard to the body-builder's requirements. Width of châssis varies also, and it is a pity that the foreign châssis is, on the whole, wider, and therefore better fitted for its purpose than the home production.

A 10-ft. wheel-base should be quite sufficient to accommodate a large-sized motor body with side entrance, but so long as engineers will insist on bringing the front axle so far forward we shall continue to have cars of unwieldy length.

A châssis should be 24 in. to the top from the ground, and in length behind the dash about 8 ft. 6 in., and not less than 35½ in. wide. From 36 in. to 42 in. should accommodate the bonnet of any engine of touring horse-power, and thus our frame should not exceed 12 ft. Other dimensions are: From dash to front of hind tyre, not less than 5 ft. 8 in., and from driver's seat to dash-board usually 24 in. The diameter of the wheels averages about 34 in.

Carriages. Horse-drawn carriages have many important differences in the matter of design to the varieties already described. Hitherto we have considered vehicles that have a foundation already prepared on which calculations have been effected, so that all strains and shocks may be safely undergone. It would be very difficult to lay down any exact laws for the guidance of the coachbuilder. Much is left to his experience and personal judgment. That opinions differ may be seen in different methods of construction and varying strengths of the members of the framework. A carriage does not run on a smooth, prepared track, although the use of some may be restricted to well-made roads. It is therefore a natural conclusion that the maker should build on the safe side in the thickness of his pillars and rails.

As the years have passed experience has taught that vehicles can be built lighter; and the adoption of suitably placed ironwork, notably mild steel, has greatly helped to this end.

Special Considerations. A coachbuilder has to allow for the attachment and safe locking, whether partial or full, of his forecarriage, and a driving-seat giving a proper control of the horses, while the occupants of the vehicle must be comfortably seated, and allowed to gain the seat in comparative ease. The builder must use turn-under and side-sweep with moderation in order that these factors in the appearance of a carriage may be displayed to their best advantage. Moreover, like a motor-car, the carriage is a vehicle made to sell and to advertise its maker, hence painting and good trimming on a well-designed vehicle are essential. The dimensions mentioned in the previous section apply also to carriages. An average width of a brougham or landau door is 21 in.; the front quarters are usually an inch or two less than those behind, partly for appearance. Sixty-three inches is a length often seen in landau elbow-lines, which would apportion out into 20 in. front quarter, 21 in. door, 22 in. hind quarter. On the other hand, 7 ft. is seen in large London patterns. Eighteen inches from the ground to the bottom of the body, adding the depth of the rocker, must be divided in order to get at the height of the body step. Adding 15 in. of leg room to the height of the bottom of the body from the ground, we have the height of the seat, which with an 11-in. quarter brings the elbow-line to a distance of 44 in. from the ground. In many types of vehicles wheels of 3 ft. and 3 ft. 8 in. diameter are found suitable.

The width is determined by the length of the seat between the pillars, and, having added our pillar substances, we next allow a clearance for the hind wheel from the panel. This wheel is less at the bottom than at the top owing to the sale. From this we find our plumb spoke, spoke mortice, length of stock, axle collar, and finally the flap which determines the position of the spring.

The coachbuilder, like other vehicle builders, has to dispose of his glass frames and has to arrange for the folding heads of landaus and landaulettes. In all vehicles climatic conditions have to be considered, and the export trade of any firm calls for much thoughtful procedure.

Road Trade Vehicles. We should endeavour to construct a vehicle with as small a tare weight in proportion to the load carried as is compatible with safety. The area for actual use is decided after provision has been made for the driver, and, if it be mechanically propelled, for the works. As in motor carriages, the disposal of the engine under the footboard gives a great saving in length. In some types of horse-drawn vehicles, such as pantechnicons [**2**, page 2463] and mineral water vans, the driver's seat does not detract from the loading area.

In a furniture van we seek to remove a large load at once and to store it safely during its transportation. As many of the articles are heavy and require delicate handling, the load is kept low. A piano van requires great width to take at least a grand piano.

Plate-glass vans need a large flat space wherever the sheets may be placed. The floating raves are designed with that purpose. Sometimes hinged sides carry the load vertically. A brewer's dray must be strong enough to carry heavy casks, with standards capable of adapting themselves to the shape of the barrels. Hay and straw require that ladders shall be built over the horse and out at the back in order to insure a paying load per vehicle. Dairy vans, carts, and perambulators should be designed with regard to hygiene and convenient handling of the churns and cans.

Coal, refuse, and similar commodities do not demand a highly finished vehicle, but rather strength combined with effectual means of keeping the load within its barriers. A means of emptying the van quickly is often provided.

Heavy articles, such as safes, stonework, and machinery, necessitate very strong vehicles, hung low, often on cranked axles. Butchers' [**14**, page 2463] and fishmongers' vehicles, and those appertaining to the perishable goods' trade, are usually well ventilated. The conveyance of water, cattle, game, and timber all call for designs of a specific nature.

Barrows, Trucks, and other Hand Vehicles. These little vehicles, depending on manual effort for their propulsion, are a vast army in themselves, there being at least one large firm that makes an interesting volume simply by illustrating the varieties. We are all familiar with the baker's barrow [**9**, page 2463]. Its handles must be of convenient height, space must be apportioned for enough bread to last the round, and the ability to get at the last loaf must not be forgotten. The coster and his barrow with its super-imposed tray is familiar. The grocer, oilman, greengrocer and fruiterer, all have many varieties of hand-carts. The builder's brick truck, and types used for shipping baggage, are fitted with means of being handled by the crane. Then there are special trucks for handling the huge reels of wallpaper, linoleum, and virgin newspaper.

Biscuits, cakes and butter have trucks of their own for factory use, and movable tables for draining milk-cans, beer and mineral water bottles, have been ingeniously designed. Trucks are also mounted on cycle wheels, and the bodies are of iron or wooden open framework, or the body is panelled. Some types are made to run on rails. Also bakers and laundry proprietors have the bodies of their vehicles made of basket work.

Ventilation, heating, lighting, and other considerations will be treated under Body-making in a later section.

Continued

A SHORT DICTIONARY OF VEHICLE CONSTRUCTION

ARCH—(1) the cavity in the body for the reception of the front wheels in turning, or (2) the foundation on which some motor-car seats are built.

Axle—The rod connecting the wheels, either stationary or rotating with the wheels.

Axle Arm—The portion of the axle passing through the hub of the wheel.

Axle Bed—(1) the central portion of the axle (between the wheels), or (2) the bottom bed in the under-carriage.

Axle Collar—Projection which retains wheel from moving towards bed of axle.

Axle Flap—The resting place of the springs on the axle.

BACKSTAY TO WHEEL IRON—The iron stay connecting the bottom bed and the futchell or futchell stays—a continuance of the wheel iron.

Barker—A London style of carriage much after French taste.

Barouche—A four-wheeled canoe-shaped carriage with folding head to hind and flap to front seat.

Bars—Body framing otherwise than pillars.

Batten—Panel backing.

Bed—Under-carriage members, especially those carrying the perch bolt.

Bed Plate—A strengthening medium to the above.

Berline—A limousine type of motor body with a special round glass corner at back.

Body Loop—The connection between the body and hind C-spring braces.

Bogie—A four- or six-wheeled truck, free to move on a central pivot. Adapted to long rail vehicles.

Bolster—A rail carriage-builder's, and wheelwright's term for "bed."

Boot—That part carrying the driving-seat, or the panel or portion below the seat line.

Bracket—The footboard support.

Broad Lace—Wide coach lace for trimming doors, making pillar holders, etc.

Built-up Roof—Roof made of three or more ply veneer.

CANT—The geometrical assembling of the various parts of the body in order that the different bevels, position of joints, and other considerations, may be noted to effect an accurately constructed body.

Cantrail—The member which joins the tops of the standing and corner pillars.

Cape Cart—A South African type of two-wheeled cart, specially yoked to the horses.

Cape Cart Hood—A folding head used with the above and adapted to motor cars.

Carriage—A vehicle for private use, or the undergear of a vehicle.

Carrosserie (*Fr.*)—Bodywork.

Cee-spring Block—Block inserted between beds and "C" springs.

Châssis—The motor-car frame with or without its machinery.

Check Brace—A strap to prevent body swaying.

Check Spring—A spring to prevent straining of the body-springs when a maximum load is being carried.

Clerestory—An additional headroom beyond the roof proper.

Collet—The outermost nut and essential feature of a Collinge axle.

Collinge Axle—An axle with right and left-handed nuts, together with a collet for retaining the wheel.

Compass—*Of a spring* the perpendicular height of the arch of the spring beyond the straight line drawn through the eyes. *Of a bed* its deviation from the straight line (generally forward) drawn through the centre of the spring bearings.

Concealed Hinge—A hinge which is hidden when the door is closed.

Coupé—A single brougham.

Coupé Limousine—As above, but capable of holding more in hind part of body, and usually with a side light.

Cradle Seat—The driving seat in a hammercloth.

Cricket Seat—A folding seat.

Cut-through Door—A method of construction bringing the door bottom in front of the rocker.

DASH—The partition between horse and coachman, and between engine and chauffeur on most cars. The point from which the motor body builder takes his body sizes.

Dish—The deviation from the square line of a wheel.

Dog-cart—A loose term, embracing many two and four-wheel carriages.

Double Deck—Provided with roof seats.

Double Extension Cape Hood—A hood shielding both seats, yet folding only from the hind.

Double-run—Provision for a wash-blind and glass frame.

Drabble Axle—Van axle.

Dumb—A member having no spring action.

EARBREADTH—The front and hind bars of a van bottom.

Edge Plate—The internal girder of a carriage body.

Elbow Line—A constructional line drawn immediately under the bottom moulding on the fence rail.

Empattement (*Fr.*)—Wheel base.

FELLOE—Section of a wheel rim.

Felloepiece—Wheel plate bearings.

Fence Rail—The central door member.

Framing Piece—The top under-carriage member running from back of bed to back of wheel plate.

Futchell—The provision for the attachment of the shafts or pole.

GATHER—The forward inclination of the axle arm.

Glass-frame Carriers—Metal supports for the glass frame in a landau or landaulette.

Guide Colour—A coat to facilitate rubbing down.

HAMMERCLOTH—The elaborated driving seat of a dress carriage.

Hansom Cab Front—An arrangement whereby shafts stop at dash and easy access is given to body.

Head Prop (hind)—The support for the open head.

Headstock—The railway equivalent to earbreadth.

Hind Cross-stay—The connection between front of hind dumbs and perch.

Hooper—A London style typical of best British practice both in outline and methods of construction.

Hoopstick—Roof-carrying members.

Horn Bar—The (usually horn-shaped) hind bar in the top carriage.

LACE—A decorated braid.

Landau—A carriage holding four in body, capable of being open or closed.

Landaulette — A brougham-shaped vehicle with advantage of landau.

Limousine—See *coupé limousine*.

Limousine Landaulette—As a double landaulette, but with the extra portion immediately behind instead of in front of the door.

Locking Stop—A projection to limit the turning of the front carriage.

MAIL AXLE—A device whereby the wheel is retained by long bolts.

Main Side—The side members of a van bottom.

Marking Out—Apportioning out the various pieces of framing on plank.

Mylord (*Fr.*)—A victoria.

OBSERVATION CAR—A railway coach designed for look-out purposes.

Omnibus—A closed vehicle to carry many, often with roof seats.

PEDESTAL—A circular block used above or below the wheel plate to make up a thickness.

Perch—The fore and hind carriage connection.

Perch Bolt—Pivot of fore carriage.

Peters—A London style, medium lines, substantial construction.

Pillar-top—Upper part of pillar in landau or similar carriage which folds down when head is opened.

Platform Suspension—Two side and two cross springs in conjunction.

Posting Landau—A landau for postillion driving.

Pump Handle—The bar connecting the hind carriage with the body.

RAVE—The upper horizontal members of a van side framing.

Rocker—The bottom connection of standing pillars, sometimes a panel below seat line or body side.

Roi des Belges—Special curved motor body first designed for King of Belgium.

Roller Bolt—The trace connection to the splinter bar.

SALISBURY BOOT—A wooden frame covered with leather found under the hammercloth.

Saloon—A railway car designed usually with long side seats.

Sham Door Pillar—The front pillar of a victoria or gig body.

Side Sweep—The external horizontal curve of a body.

Single Deck—Having no roof seats.

Standard—The uprights in a van side framing between the corner pillars, or the ornamental uprights on the platform of a hind dress under carriage.

Standing Pillars—The pillars which receive the door.

Summer—The longitudinals of a van bottom framing between main sides.

Sway Bar—Extra hind felloepiece.

Sweep Piece—The wheelwright's felloepiece.

TARE—The unladen weight of a vehicle.

Tilt—A van cover.

Tonguing Piece—The connection between the front of the transom and the front of the wheel plate.

Top Carriage—The upper part of the fore carriage including wheel plate.

Tramcar—A rail street omnibus.

Transom—The top bed carrying the perch bolt.

Turnunder—The curved vertical contraction of a carriage body.

UNDERSPRING—The side spring in a C-spring under a carriage.

VACUUM BRAKE—The railway brake applying its power by the destruction of a vacuum.

Van—A four-wheeled trade vehicle, or a closed railway vehicle not adapted for passengers.

WESTINGHOUSE BRAKE—A railway brake applying its power by the lowering of atmospheric pressure.

Wheel Base—The distance between the two axle centres.

Wheel Iron—The connection between the futchell jaw, and axle bed or splinter bar and axle bed.

Wheel Iron Head—The clip that encircles the axle bed end.

Wheel Plate—The turning plate of the fore carriage.

Wheel Track—The distance between the tyre centres.

Wing—(1) a mudguard, or (2) an additional side member to the hind end of a wooden perch.

THE GEOGRAPHY OF ASIA

Coastline. Mountain Systems and Tablelands. Roof of the World. Himalayas. River Basins. Inland Drainage. Climatic Conditions. Isotherms. Rainfall

By Dr. A. J. HERBERTSON, M.A., and F. D. HERBERTSON, B.A.

The Continent as a Whole. Asia, the largest of the continents (17,000,000 sq. miles), is surrounded by the ocean except in the west, where it is continuous with Europe. The frontier between the two does not correspond with natural features save in the Urals and Caucasus.

Coastline. The northern shores of Asia are washed by the Arctic Ocean, with one great gulf, the Kara Sea, shut in to the west by the island of Novaya Zemlya, and smaller gulfs, where the north-flowing rivers form estuaries.

The eastern coast is curiously symmetrical in the arrangement of its lands and seas. The lines of North-eastern Asia and the peninsula of Kamchatka, east of the Sea of Okhotsk, correspond closely in outline with (1) Amuria and Korea, east of the Yellow Sea; (2) China and the Island of Hainan, east of the Gulf of Tongking; and (3) Indo-China and the Malay peninsula, defining the Gulf of Siam. A sort of festooned fringe of islands extends from Kamchatka to the islands of the Malay archipelago, separating four enclosed seas from the main Pacific Ocean. These are (1) the Sea of Okhotsk, enclosed by Kamchatka, the Kurile Islands, and Sakhalin, and opening by the La Perouse Strait, between Sakhalin and the northern island of Japan, to (2) the Sea of Japan, enclosed to the east by the islands of Japan. The Strait of Korea in the south, between the Kiusiu island of Japan and the Korean peninsula, to (3) the East China Sea, enclosed on the east by the Lu-chu islands and Formosa. (4) The South China Sea is enclosed on the east by Formosa, the Philippine Islands, and Borneo, the largest island of the Malay archipelago. This archipelago, together with New Guinea, connects Eastern Asia with Australia, which many ages ago was part of the Old World.

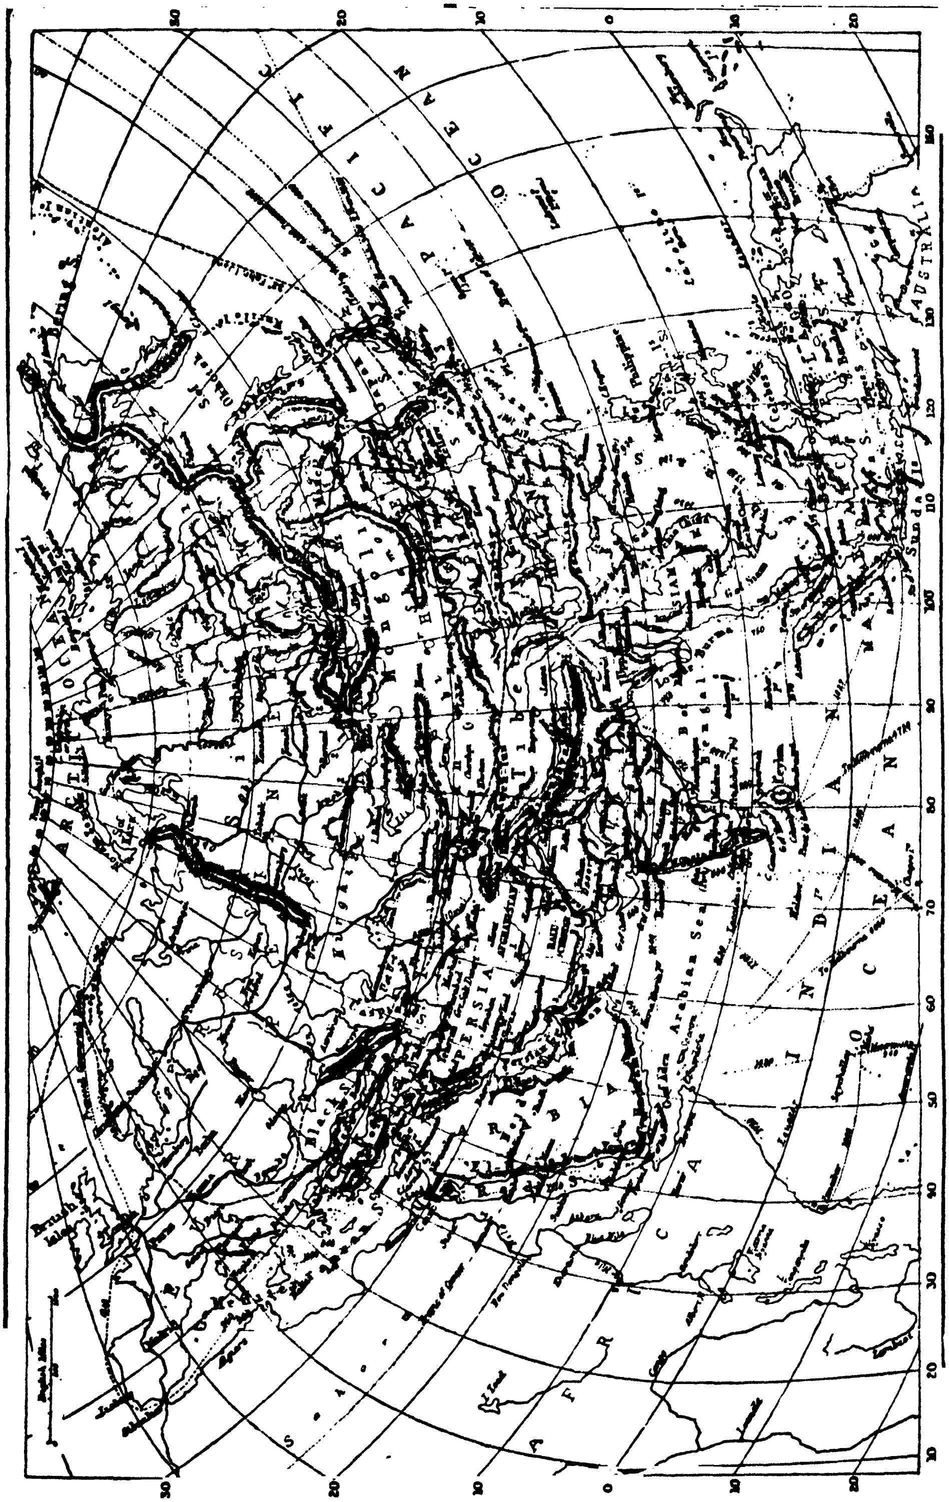
The southern coast of Asia is washed by the Indian Ocean. Like Europe, it is broken into three south-running peninsulas; (1) the Indo-China peninsula in the east, separated from (2) India, the middle peninsula, by the Bay of Bengal: and (3) Arabia in the west, separated from India by the Arabian Sea, which opens to the Persian Gulf. West of Arabia is the narrow Red Sea, separating Asia from Africa, and divided from the Mediterranean only by the narrow Isthmus of Suez, across which a ship canal has been cut.

Mountains and Rivers of Asia. We have seen that Europe and Asia really form a single continent, and that the physical features of the two are continuous. Broadly speaking, Europe is a lowland in the north and a highland in the south, and these divisions are represented in Asia by the plains of Siberia in the north, and the mountains of Central Asia. South of the latter are a series of lowlands: Mesopotamia, or the lowland of the Euphrates, in the west; the lowlands of the Indus and Ganges, or the plain of India, in the centre—both of which we may compare with the plain of the Po at the base of the Central Alps—and smaller lowlands in the east, round the rivers of Indo-China. Beyond these lowlands is the tableland of Arabia in the west, which may be compared with Spain, and the tableland of the Deccan, occupying the southern half of the Indian peninsula.

The Mountains of Asia. More than half of Asia is over 1,500 ft. above sea level. Its vast and complicated mountain systems, far greater in area than the whole of Europe, are the greatest highland area in the world in length, breadth, and height.

We began our study of the central European highlands with the Fichtel Gebirge, and of the Alps with the St. Gotthard, and similarly, dealing with the immensely complicated relief in Asia, we shall begin by looking for a centre from which the principal mountains and rivers radiate. This we find in the Pamirs, where the frontiers of Britain, Russia, China, and Afghanistan meet. They form a desolate plateau, some 150 miles both in breadth and length, which the inhabitants well call the Roof of the World.

The Roof of the World. This is how the Roof of the World is described by a traveller approaching it from the north. "Approaching this interesting region from Kashgaria, one sees clearly how it has acquired the name of the Roof of the World. The Pamir mountains rise apparently quite suddenly out of the plain, from a height of 4,000 ft. above sea level at their base, to over 25,000 ft. at their loftiest summits, a massive wall of rocks, snow, and ice. Once through the gorges which lead up from the plains, one enters a region of broad, open valleys separated by comparatively low ranges of mountains. These valleys are known as Pamirs, a term applied by the natives of these parts to a particular kind of valley. In the Hindu Kush and Himalaya regions the valleys, as a rule, are deep, narrow, and shut in. But on the Roof of the World they seem to have been choked up with the débris falling from the mountains on either side faster than the rainfall has been able to wash them out, and so their bottoms are sometimes as much as four or five miles broad, and almost level. These Pamirs vary from 12,000 or 13,000 to 14,000 ft. above sea level—that is, the bottoms of these Pamir valleys are level with the highest summits of the Alps."



101. MAP OF ASIA

For the greater part of the year they are buried in snow, but during the few weeks of summer there is a fair abundance of coarse but nourishing pasture, which attracts a few wandering Kirghiz herdsmen and their flocks to this desolate region.

The Pamirs as a Mountain Centre. From the Pamirs radiate the chief mountain systems of Central Asia. These are (1) the Tian Shan, running north-east, in a direction which is continued by the Altai, Yablonoi, and other mountains which form the northern rampart of the mountain core of Central Asia. From the northern valleys of this rampart, which slopes to the vast plains of Northern Asia, descend the rivers of Siberia—the Ob, Yenisei, and Lena—while the great Amur, flowing east to the Sea of Okhotsk, gathers up the waters of the southern and eastern valleys. Between (1) the Tian Shan and (2) the Kwenlun, the next well-defined system radiating east from the Pamirs, are enclosed the Tarim basin and the tableland of Mongolia. Besides forming the southern wall of this plateau, the Kwenlun is, as it were, a natural stair leading to a still loftier plateau, whose valleys lie but a few thousand feet below the summits of its highest peaks. This is Tibet, the highest inhabited land in the world. The next system is formed by (3) the Karakoram, or Muztagh Mountains, and (4) the mighty Himalayas, the most imposing system in the world. Its northern ranges form the southern rampart of the Tibetan plateau, while the southern descend steeply to the plains of India, 20,000 ft. or more below.

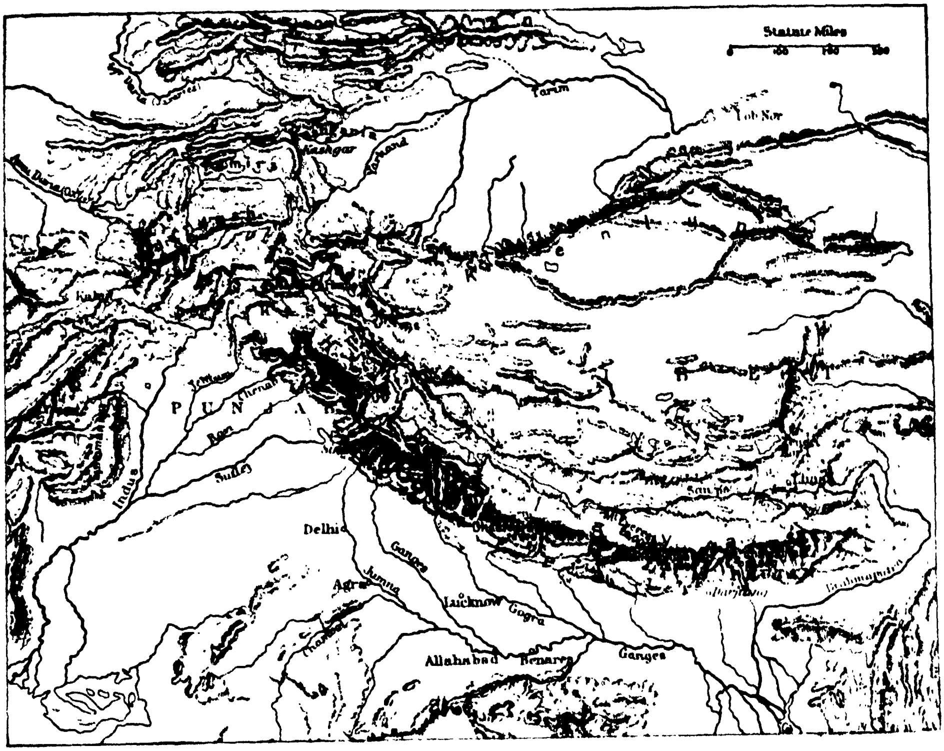
The Himalayas. No words, or even pictures, can give an idea of the wonders of the Himalayas. Seen from the plains of India, they consist of low hills, not over 2,000 ft., with ranges behind rising to 8,000 or 9,000 ft., and behind these again, to snowy summits, over 25,000 ft. At the base lies a broad strip of malarious jungle, called the Terai, with a heavy rainfall and continuous floods, so that the waterlogged soil is pestilential with decaying vegetation. Above this is the forest zone. The ascent is very rapid. In 35 miles the railway to Darjiling, in the Sikkim Himalayas, climbs over 7,000 ft. "The whole range may be described as a stupendous stairway hewn out of the western border of the Tibetan plateau by glaciers and great rivers. It is cut into countless peaks and ranges, with valleys of corresponding depth, down which dash thundering torrents. The deep gorges of the rivers so interpenetrate the mountains as to carry a hot climate far along their banks, till the semi-tropic vegetation becomes almost overhung by snowy peaks." This is true only of the valleys opening south to the plains of India. Those enclosed between the ranges of the Himalayas are as terrible in their desolation as in the wild character of their scenery.

A Himalayan Road. Lord Curzon thus describes his march along the upper valley of the Hunza, a tributary of the Indus: "The river cuts a deep gash or furrows an uproarious channel in its descent from the watershed of the Pamirs. Big glaciers propel their petrified cascades to the very edge of the river. Sometimes the road is conducted round the edge of the precipices that overhang the torrent by artificial ladders and ledges, built out from the cliff with stones loosely laid upon supports of brushwood and timber jammed into the interstices of the rock. Over this vile stretch of country there are two tracks, the upper, or summer track, which avoids the river-bed, filled with a fierce and swirling torrent, and climbs to the summit of the cliffs, several thousand feet above the water, and the lower, or winter track, which can only be pursued when the melting of the snow by the hot summer sun is over, and the river dwindles to a number of fordable channels, across and amid the boulder-piled fringes of which the traveller picks his way." Up very similar roads lay a great part of our Army's ascent in 1904, by the gorges of the Sikkim Himalayas to the plateau of Tibet above. They made their way through dense forests, with a hothouse temperature and tropical vegetation, through woods of oak, chestnut, maple, ash and elm, through open snow and sprinkled pine-forest, emerging at last above the blazing rhododendrons which grow just below the snow line into open, undulating stretches of Alpine pastures, in full view of the great snow peaks.

Peaks of the Himalayas. Only a few of these can be named, for there are scores of peaks over 20,000 ft., presenting some of the finest scenery conceivable. In Kashmir, through which the Pamirs are approached from India by the Hunza Valley, the peak most admired by travellers is Nanga Parbat (26,600 ft.). In the Himalayas of Nepal is Dhaulagiri (26,800 ft.), while the monarch of the Sikkim Himalayas is Kanchenjunga (28,200 ft.), surrounded by peaks almost as high. Chamalhari (24,000 ft.) greatly impressed our troops who passed close below it in the Tibetan expedition, but the monarch of the Himalayas, as of the world, is Mount Everest (29,000 ft.), first seen from the Tibetan side in all its grandeur by European eyes in the summer of 1904. Hitherto the giant had been seen only from the south, almost completely hidden by the mighty peaks between.

A Glimpse of Mount Everest. "Towering up thousands of feet, a glittering pinnacle of snow, rose Everest, a giant among pigmies, not only on account of its height, but for its perfect form. To the east and west, but nowhere in its immediate vicinity, rise other great mountains of rock and snow, each beautiful in itself, but in no way comparing with the famous peak in solemn grandeur. It is difficult to give an idea of its stupendous height, its dazzling whiteness and overpowering size, for there is nothing in the world to compare it with." Thus writes the first Englishman who saw it, settling for ever the doubt whether still higher peaks might not exist on the Tibetan side. For the present, Mount Everest reigns as the unchallenged monarch of the world.

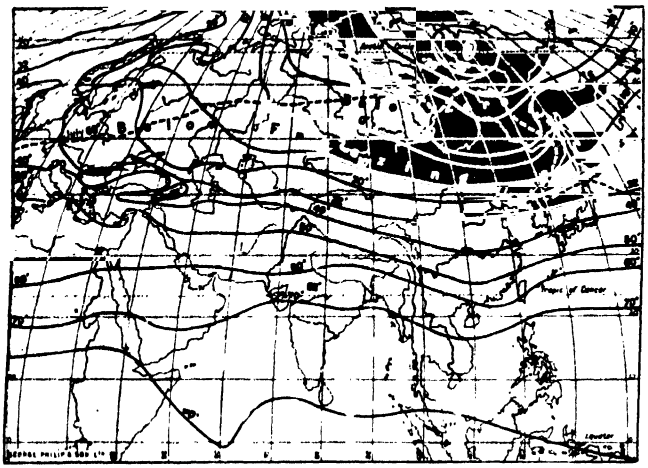
The Hindu Kush. Returning to the Pamirs, to reach which from Mount Everest we should have to cross Tibet and Kashmir



105. THE ROOF OF THE WORLD

by innumerable passes thousands of feet higher than the highest summit of the Alps, through some of the grandest and some of the most desolate scenery in the world, we now continue our examination of the mountain systems connected with the Roof of the World. They no longer run east, but west, interposing a mountain barrier hundreds of miles wide between the plains of India and the steppes of Russian Asia. They are known as (5) the Hindu Kush, the direction of which is continued west by the Elburz Mountains, at the southern margin of the Caspian Sea, to the highlands of Armenia, the centre of the West Asian mountain systems, and (6) the Suleiman Mountains, which run south, and form the western wall of the plains of India and the eastern rampart of the plateau of Iran, a smaller and lower Tibet.

The Rivers of Central Asia. We can now fill in the rivers connected with the great mountain systems of which the Pamir plateau is the centre. The glaciers of the western valleys of the Pamirs and the northern valleys of the Hindu Kush give birth to the feeders of the famous Oxus, or Amu Daria, which leaps down through stupendous and often impassable defiles, between walls of bare, treeless rock, to the lowlands of Turan, whose dry sands it crosses to the land-locked Sea of Aral, to which also flows the Jaxartes, or Syr Daria, from the Tian Shan. From the north-eastern glaciers of the Karakoram, above which peaks rise to over 28,000 ft., rushes down the Yarkand river, which unites with many other raging streams from the Tian Shan and Kwenlun to form the Tarim. The Tarim crosses the deserts of Eastern Turkestan, and loses itself at last in the marshes of the disappearing lake of Lob Nor. Greater than either of these is the mighty Indus, which rises deep in the fastnesses of the Himalayas, its upper valleys forming a series of appalling defiles, through which an inky torrent thunders at the base of sheer walls of rock, many thousands of feet in height. It is turned south by the wall of the Hindu Kush, and flows south-west at the base of the Hindu Kush and Suleiman Mountains to the Arabian Sea. As it crosses the plain of Northern India it receives many long tributaries from the Himalayas, the greatest being the Sutlej, which has risen not far from the Indus itself, and broken through range after range of the Himalayas in its wild course to the plains below. A third river, rising quite near the Indus and the Sutlej, but finding its escape along the Tibetan base of the Himalayas, is the Brahmaputra, whose course follows the direction of the Himalayas till these begin to break up and bend south. Then the Brahmaputra also turns south, and, leaping down the mountain terraces of Assam, flows at last to the delta of the Ganges. The Ganges is formed by the union of many great rivers, which thunder down in parallel valleys from the southern slopes of the Himalayas, their sources not far, as the crow flies, from those of the feeders of the Indus and Sutlej, but separated from them by what are, for man, insuperable barriers.



106. JANUARY ISOTHERMS
The July isotherm of 68 deg. is indicated by a broken line

The Mountains and Rivers of Indo-China. In the wild and little-known regions on the frontiers of Tibet and Eastern China, at the eastern end of the Kwenlun, we have another of those central points from which a whole series of mountains and rivers radiate. Here the Hwang-ho, or Yellow River, of China rises in the mountain fastnesses of north-eastern Tibet, leaps down to the plateau of Mongolia, and breaks away south across the North China highlands, which spring from the eastern Kwenluns and mark the end of that long line of elevation, running from west to east, which we have traced from the shores of the Bay of Biscay to the eastern confines of Asia. Here, where it ends, internal convulsions have crumpled the Earth's crust into complicated folds, which diverge in all directions, north-east in the North China highlands, east in the highlands which separate the Hwang-ho from the Yangtse-kiang, the second great river of China, and south in the parallel ranges which lie east of the Himalayas and the valley of the Brahmaputra. A whole series of parallel valleys, running first east and then south, are filled by the tributaries of the Yangtse-kiang and by the upper courses of the rivers of Indo-China, the Irawadi, the Salwen, and the Mekong.

The Armenian Highlands. To the highlands of Armenia, between the Black Sea and the Persian Gulf, converge (1) those mountains which continue the direction of the Hindu Kush and form the northern rampart of the plateau of Iran, and (2) those which spring from the base of the Suleiman Mountains and are continued along the Persian Gulf to the mountains of Kurdistan, forming the southern rampart of the same plateau. From the Armenian highlands diverge to the west the northern and southern mountain-walls of the plateau of Asia Minor, the latter known as the Taurus Mountains. The rivers of the Armenian highlands are the Euphrates and Tigris, flowing from the southern valleys to the Persian Gulf, forming in their lower courses the plains of Mesopotamia, and the Aras or Araxes, flowing east, and separating Armenia from the Caucasus.

The Mountains of Eastern Asia. Volcanic activity is very conspicuous in Eastern Asia, where a broken chain of volcanic mountains runs through Kamchatka, the Kurile Islands, Japan, the Luchu Islands, the Philippines, and some islands of the Malay archipelago, where disastrous manifestations of volcanic energy occur from time to time.

Basins of Inland Drainage. We saw that one large river of Europe, the Volga, flows, not to the open sea, but to the land-locked Caspian, which occupies part of a great depression which may be traced as far as the Sea of Aral. Areas drained in this way to lakes or inland seas are called basins of inland drainage. We have had other examples in the Amu Daria and Syr Daria, both flowing to the Sea of Aral, and in the Tarim, which loses itself in the marshes of the vanishing lake of Lob Nor. The total area of inland drainage in Asia is estimated at 4,000,000 square miles, an area greater than the whole of Europe.

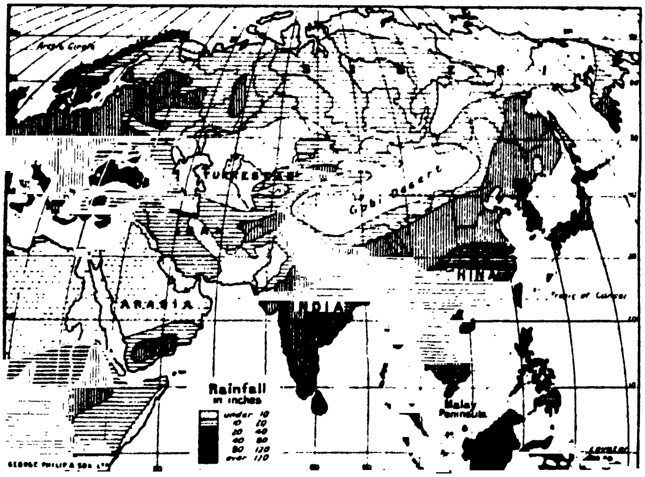
The Desiccation of Asia. Lake Lob Nor is disappearing because it is gradually drying up. There is some evidence to show that the climate of Asia is probably slowly becoming drier. Not merely are some of the lakes and rivers shrinking, but the desert sands seem to have invaded once fertile tracts. "Whole kingdoms have disappeared, many cities have been swallowed up in the sands, and certain tracts formerly accessible to travellers can no longer be visited owing to the total absence of water and vegetation."

Climate of Asia. We now know enough about geographical laws to find out a great deal about the climate of Asia. We have many data to go upon. In the first place, Asia stretches from about lat. 77° N. to within 100 miles of the equator, which crosses the islands of Sumatra and Java. This gives every possible variety of climate so far as this is affected by latitude. The regions round the Caspian and Aral Seas are below sea level, while Mount Everest is nearly six miles above it. This gives us every variety of climate so far as this is determined by elevation. Thirdly, the continent is enormously longer and broader than Europe, and on one side it is surrounded by the land masses of Europe and Africa, so that no oversea winds can come from that quarter. Further, while Europe is broken up into peninsulas and inland seas, Asia is extremely compact, so that while places in the centre of Europe are only hundreds of miles from the sea, in the centre of Asia they may be thousands, and between them and these distant seas are interposed ranges of lofty mountains which intercept all oversea winds. Putting all these facts together, we should say (1) that the climate of Asia is very varied, and (2) everywhere extreme, but (3) most extreme in the centre of the continent, and (4) that, except round the margin of the Pacific and Indian Oceans, the rainfall must be scanty, and (5) that the interior must be practically a rainless desert. This is exactly the real state of the case.

January Isotherms. In the maps which show the isotherms for January, we see the distribution of winter cold. We do not expect to find the great southward sweep of the winter isotherms which was so marked in the case of Europe, for this indicated a change from oceanic to continental climate. There is no such sharp transition in the case of Asia, which has the continental climate of Russia in a more intense form. The increasing severity of the winter cold as we go east is indicated by a steady instead of a sudden dip southwards. The isotherm of 32°, indicating freezing point, which we traced in Europe as far south as the Black Sea, crosses the Caspian Sea, the Upper Oxus, and the lands north of the Himalayas, and then curves northwards through Korea, and north of Honshiu, the largest island of Japan. South of this line, which runs much further south than the most southern point of Europe, there are no continuous frosts in the plains, though any degree of frost may be experienced at a sufficient elevation. North of it frost lasts weeks or months, its severity and duration increasing as we go further north, higher, or further into the interior. The line of 0° F., indicating 32° of frost, includes most of the north-eastern part of the continent, and this is not the minimum winter temperature in Northern Siberia, for at Verkhoyansk it is under—50° F. South of this isotherm of 32° the combined influence of low latitude and proximity to the sea is markedly felt. The isotherm of 50° is comparatively near that of 32°, and the lowlands of Arabia, India, Southern China, and Indo-China, have winters as warm, or warmer than this. The winters of the southern lowlands of the three peninsulas are considerably warmer than the summers of the Thames Valley, the warmest part of the British Isles.

July Isotherms. The summer isotherms show us, as we might expect, that the hottest summers occur in the southern part of the continental area proper, in which we may include most of Arabia, as the seas on either side are too narrow for cooling winds to develop. The true peninsular regions—the extreme south of Arabia, the Deccan, and Southern Indo-China—are somewhat cooler, though, of course, very hot. The isotherm of 68°, the summer temperature of the hotter parts of Central Europe, extends considerably north of Lake Baikal, but sinks southwards in Amuria, and passes completely north of Honshiu. Even in the tundra the summer temperature is as high as 50°. As the winter temperature of the same place is many degrees below freezing point, the range of temperature is enormous, especially in the centre and east.

Rainfall. Turning to the rainfall, we find that five great areas: (1) in Northern and Eastern Siberia, (2) in Russian Turkestan, (3) in Chinese Turkestan, (4) in Iran, and (5) in Arabia, receive less than 10 in. of rain in a year, and are rainless deserts except where irrigation is possible. These are surrounded by equally extensive regions where the annual rainfall is under 20 in., as dry, that is, as the drier parts of Spain and Russia. The only well-watered regions are maritime China, Indo-China, and India south of the desert, round the Lower Indus. Parts of Southern China, North-east India, Burma, Siam, and the Malay peninsula have a very heavy rainfall, as have also the Western Ghats, the western mountains of peninsular India, and the Malay Archipelago.



107. THE RAINFALL OF ASIA

The Monsoons. Some of these wet areas lie in the equatorial belt of rain at all seasons, but much of the rainfall of Southern China, India, and a small wet area in South-west Arabia, is brought by the summer monsoon, the cause of which has already been explained.

Continued from page 2509

By WILLIAM R. COPE

Ornament for the Circle. Fig. **596** is a mediæval design for a wrought-iron key handle; **597** is a Gothic design for chip-carving; and **598** is taken from a Romanesque portal, designed in the twelfth century.

The Oblong Panel. The usual subdivisions of this shape are shown in **599** and **600**, while **601** is suitable for a tablet, and **602** for door panels or the soffits of arches.

The Trapezium Panel. This shape may be divided as indicated in **603** and **604**.

The Hexagonal Panel. Two examples of the usual subdivisions for panelling are given in **605** and **603**.

The Rhombus Panel. This is often called the "Lozenge" shape, and may be subdivided as in **607** to **609**.

GOTHIC TRACERY

The Gothic style evolved and brought to perfection a characteristic decoration known as Tracery, by means of arcs of circles. These designs possess great originality, and richness of form, although they are somewhat stiff and mechanical when compared with designs founded on Nature in other styles.

Tracery is chiefly applied to stone and wood used in architecture; for galleries, windows, panels, etc., and for furniture.

Fig. **610** is the necessary construction for **611**, a design for a square panel; **612** shows three foliations for a circle; and **613** is the planning for a rose window, or for a circular panel.

Fig. **614** is the foundation for **615**, a curvilinear triangle, and **616** is a design for tracery for an equilateral triangular panel, suitable for woodwork or stone. In **617** is given the construction for **618**, the tracery which might be used for a window or a screen. Fig. **619** contains the foundation lines for **620**, a design for the head of a four-light window.

Many other beautiful examples of tracery can be found in good textbooks on Architecture.

ARCHES

The arch is a very ancient construction, and has appeared in many forms from the Classic periods. The Romans were the first to use the arch extensively in architecture, even if they were not the originators of this form. The earliest shape of the arch was semicircular [**621**], and this was in succeeding centuries changed to the various forms shown in **622** to **632**. The latter are only typical examples, which illustrate the arches in general use, and although the centres are shown from which the curves are struck, those centres, in most cases, may be varied in position.

The names of the individual parts of an arch are given in **621**.

Various Forms of Arches. The *segmental* arch may be struck from one centre as in **622**, or from two centres as in **623**. Fig. **624** is one form of the *horseshoe* or *Moorish* arch. The *equilateral* arch, much used in Gothic architecture in the thirteenth century, is shown in **625**. In the twelfth century the *lancet* arch [**626**] was very common, as also was the *obtuse* arch [**627**].

The *three-centred* arch given in **628** is constructed by first determining the height and the span; then make *AC*, *BC*, and *DE*, all equal. Join *EC* and bisect in *F*. The intersection *C* of the bisecting line *FC* with *DE* produced is the third centre. Describe arcs from *C*, *C*, *C*, as centres.

The *depressed Tudor* arch [**629**] is described from four centres. The *ogee* arch, or so-called ass's back, has either three [**630**] or four centres [**631**]. The *pointed trefoil* opening has the centres placed as shown in **632**. The parabola and ellipse may also be used for arch forms.

MOULDINGS

In architecture mouldings form a constituent part of an order, and were used in eight forms by the Romans and the Greeks. These forms are named: the *fillet*, a narrow, flat band used to separate and combine curved mouldings; the *astragal* or *bead*, a narrow or small convex cylindrical moulding [**634**]; the *torus* [**635**], which is really a large form of the astragal, and is often used at the base of columns; the *ovolo*, or *echinus* (meaning "egg-formed"), a convex moulding [**638** and **644**], which appears to have originated in the capital of the Doric column; the *cavetto* [**639** and **645**], which is the reverse of the ovolo; the *scotia* [**640** and **646**], a concave moulding which gives a deep shadow on itself and is very effective when used on bases of columns; the *cyma recta* [**641**, **642**, **647**, and **648**], a moulding with the concave above the convex portion; and the *cyma reversa* [**643** and **649**], which has the convex part uppermost.

Besides the above, the *chamfer* [**633**], the *reeds* [**637**], and the *flute*, a concave channel used to ornament the shaft of a column, are often used.

The characteristic difference between Greek and Roman moulding is that the former are described with parabolic, hyperbolic, and elliptical curves, and the latter with arcs of a circle; but the Greek are more graceful in contour.

The mouldings were often decorated with carving or colour, a particular design being used for each moulding, as in **638** and **649**.

STABILITY OF STRUCTURES

continued from page 2149

STABILITY OF WALLS

Stability Against Overturning and Crushing. Boundary Walls. Buttresses. Retaining Walls. Surcharged Walls. Dams

By Professor HENRY ADAMS

General Principles. The simplest case of the stability of a wall will occur when the wall is considered to overturn by pressure on one face without crushing the edge, which acts as a fulcrum. This can happen only when the total weight of the wall is very small. It is usual to consider one foot of the length of wall, as every foot will be similar, except in the case of walls with buttresses or counterforts. In **211** is shown the section of a wall, ABCD, of weight *w* per foot cube, height *h*, thickness *t*, total weight W, acted upon by a pressure *p* per square foot against one face, giving a total pressure P. Then $W = wht$, acting at the centre of gravity of the wall, and $P = ph$, acting at the centre of the height. Produce P through the centre of gravity of the wall and drop W from the same point, then find the resultant of the two forces by means of the parallelogram of forces. So long as the resultant cuts the base line within the wall, the wall will be in stable equilibrium; but should the resultant cut the base outside the wall, the wall will overturn. To find the maximum pressure per square foot for equilibrium,

$$\tfrac{1}{2}h : wht :: \tfrac{1}{2}t : ph,$$

whence,

$$ph = \frac{wht \times \frac{1}{2}t}{\frac{1}{2}h} = wt^2;$$

or,

$$p = \frac{wt^2}{h}.$$

From this equation it will be seen that the stability varies directly as the weight per cubic foot and as the square of the thickness, and inversely as the height. It must be observed also that the moments of the forces are equal—*viz.*,

$$P \times \tfrac{1}{2}h = W \times \tfrac{1}{2}t.$$

There is another possible mode of failure without crushing, and that is by pushing the wall off its base. This may happen if the wall is very thick compared with its height, and the pressure against the face is sufficiently great to cause the wall to slide without overturning. The coefficient of friction of fresh mortar may be taken as 0·5, so that when $P = \frac{1}{2}W$ and the resultant cuts the outer edge of base, the tendency to overturn or slide will be equal.

Distribution of Pressure on Base of Wall. A wall of rectangular section, built upright, and subject to its own weight only, produces a uniform pressure over the base, because the resultant meets it in the centre, as shown in **212**. The diagram at base of wall represents the ordinates of pressure. If a pressure acts against the wall horizontally at any point, the amount of total vertical load is not altered, but the resultant, or centre of pressure on the base, is pushed further over, causing an increase in the intensity on the outer edge and a reduction on the inner edge. If the horizontal pressure be sufficient to push the resultant over to the edge of the *middle third* of the base, as shown in **213**, the pressure will be increased to double at the outer edge and reduced to nothing at the inner edge. A wall under such conditions is generally considered to be absolutely safe, but it may not be really so, as the height, and consequently the weight, may be so great that doubling the pressure on the outer edge may produce a greater intensity than the material is capable of bearing. On the other hand, the resultant may pass beyond the middle third and the intensity of pressure still not be so great as to exceed the safe stress upon the material.

Resultant Beyond Middle Third. When the resultant passes beyond the middle third of the base, there are two cases to consider—one where the material will not bear any tension, and the other where tension may be allowed. Taking the former case, and assuming that the resultant passes at one-fourth the width of base from the outer edge, the maximum pressure in tons per square foot will be

$$p = \frac{2}{3} \cdot \frac{W}{d},$$

where $W =$ total load in tons, and $d =$ distance from resultant to outer edge in feet. Graphically, the triangle giving the ordinates of pressure will be carried back along the base twice the distance *d* from the resultant towards the inner edge, and the remainder of the base will be under no pressure, as in **214**. This formula is due to Professor Crofton, of the Royal Military Academy, Woolwich, and is generally accepted as giving a true result, although there are other possible views of the case.

When tension is permissible, the maximum pressure at outer edge and tension at inner edge are given by the formula

$$p = \frac{W}{A} \pm \frac{M}{Z},$$

where W is the vertical component of the resultant, A the sectional area of the base, M the bending moment—*i.e.*,

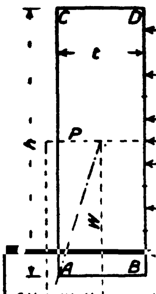
$$W(\tfrac{1}{2}t - d),$$

and Z the modulus of section—*i.e.*,

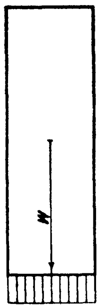
$$\tfrac{1}{6}(t \times 1^2) = \tfrac{1}{6}t;$$

the + value giving the intensity of the compression and the − value the intensity of the tension, as shown in **215**.

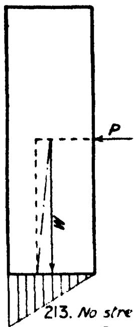
Boundary Walls. A boundary wall when newly built will come under the rule for **214**,



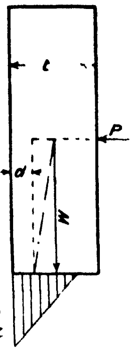
211. Wall on point of overturning



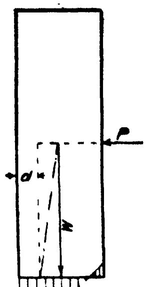
212. Base of wall under uniform pressure



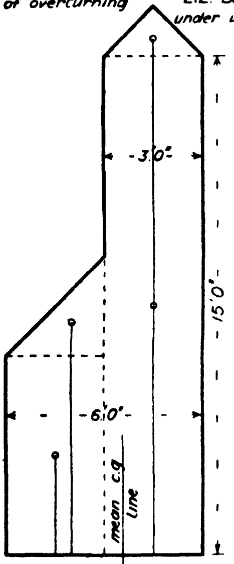
213. No stress on inner edge Resultant at middle third



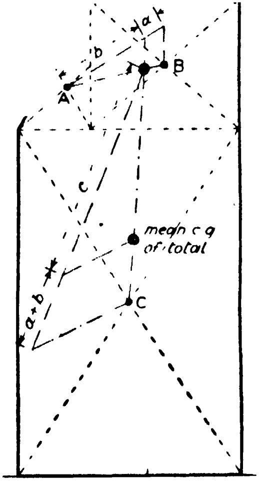
214. Resultant at one-fourth of base and no tension



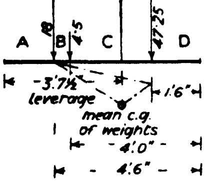
215. Resultant at one-fourth of base and tension allowed.



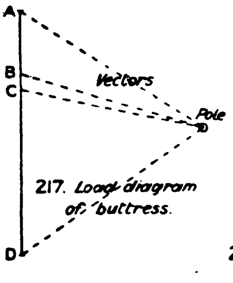
216. Elevation of buttress



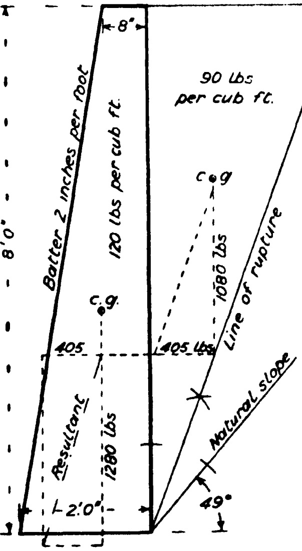
219. To find centre of gravity graphically



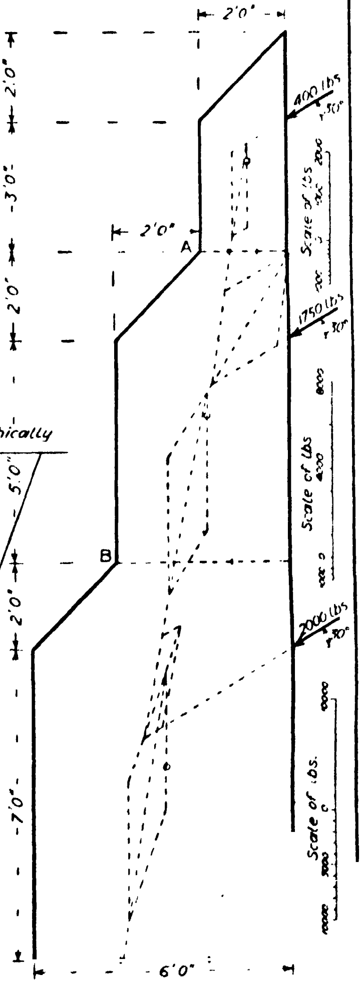
218. Funicular polygon to give mean centre of gravity.



217. Load diagram of buttress.



221. Retaining wall for earth.



220. Buttress with thrusts.

but when the mortar has set it will be to the rule for **215**. The safe proportions for thickness and heights of boundary walls are given in the following table.

Safe Proportions for Boundary Walls.

9 in.	Up to	6 ft. 4½ in. high.
14 ,,	.. ,,	9 ft. 7½ in. ,,
18 ,,	.. ,,	13 ft. 0 in. ,,
23 ,,	.. ,,	16 ft. 6 in. ,,
27 ,,	.. ,,	20 ft. 4½ in. ,,

Stability of Buttresses. A buttress may be calculated as part of a wall, in which case the length is taken to include one buttress and the wall for half the distance towards the other buttresses on each side. This is, however, rather a troublesome calculation, and a buttress is often calculated by itself, especially when it is a large one to take the thrust of a roof truss, as with public halls and churches having hammer-beam trusses. The thrust upon each part of a buttress and the weight above the horizontal line for which the calculation of stability is made, are combined in a parallelogram of forces; but it will first be necessary to find the vertical line through the mean centre of gravity. This is most easily done by marking the centre of gravity of each part, as in **216**, and drawing force-lines through the points to meet the base. The weight of each part may be taken as acting through its centre of gravity to give the value of each force, and then, the load-line [**217**] being drawn, a pole is selected and vectors drawn from the points on the load-line to the pole. The force-lines in **216** may then be drawn down on to a separate line, like a beam [**218**], and the funicular polygon constructed by drawing lines parallel to the vectors, when the intersection of the closing lines A and D gives the position of the mean centre of gravity.

Another method of finding the mean centre of gravity of any number of separate parts is shown in **219**. First mark the centre of gravity of each part A, B, and C, then join A and B and at any angle draw a line upon which the weights of A and B are to be set off to scale in inverse order, as shown by *ba*, join the extremity with B, and at the junction of *a* and *b* draw a parallel line to cut AB at the mean centre of gravity. Join this with point C and repeat the operation as indicated, when the mean centre of gravity of the whole figure will be obtained. Applying those principles to an actual buttress [**220**] it will be necessary to ascertain the stability at each minimum section, thus, at A and B. Find the centre of gravity of the portion above A, and then of the part between A and B. Taking the part above A, first combine by parallelogram of forces the thrust and the weight to give the resultant shown, which is found to cut the base just within the middle third; then, producing this resultant, combine it with the next thrust to produce another resultant. It will be well to reduce the scale wherever necessary to prevent the parallelogram becoming unwieldy, as in this case. The last resultant will now be combined with the new weight and a new resultant will be found which also cuts the base just about the edge of middle third. This will show that the buttress is safe provided the intensity of the pressure be not too great. This pressure, with the resultant at edge of middle third, will be $= 2 \times \frac{W}{A}$, where W is the vertical component of the resultant and A the area of base.

Stability of Retaining Walls. A retaining wall is a wall of brick, stone, or concrete to hold up the earth at a change of level, as in a railway cutting through a town where there is not sufficient space available to allow of side slopes being formed. The pressure of the earth depends upon its *natural slope*—that is, the slope it would permanently retain if a bank of it were left exposed to the weather for an unlimited time. It may be taken generally as 30 degrees from the horizontal when the conditions are unknown, but the following table shows the natural slopes for ordinary soils as given by Rankine:

Table of Natural Slopes.

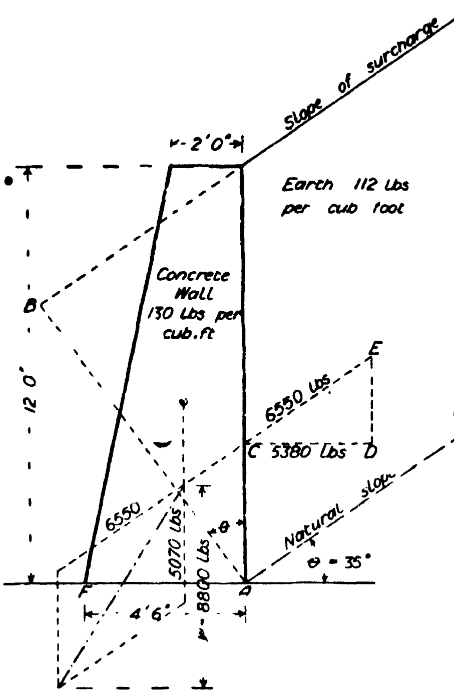
	Degrees.
Dry sand, clay and mixed earth ..	21 to 37
Damp clay	45
Wet clay	14 to 17
Shingle and gravel	35 to 48
Peat	14 to 45

This angle is sometimes called the *angle of repose*, but it means the same thing, as in the following table from "Notes in Building Construction," Vol. IV.:

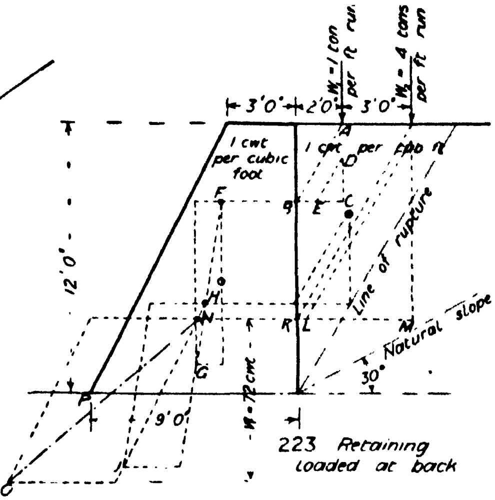
Angle of Repose of Various Earths.

	Degrees.
Fine dry sand	37 to 31
Sand, wet	26
Vegetable earth, dry	29
,, ,, moist	45 to 49
,, ,, very wet	17
,, ,, consolidated and dry	49
Loamy earth, consolidated and dry	40
Clay, dry	29
,, damp, well drained	45
,, wet	16
Gravel, clean	48
,, with sand	26
Loose shingle	39

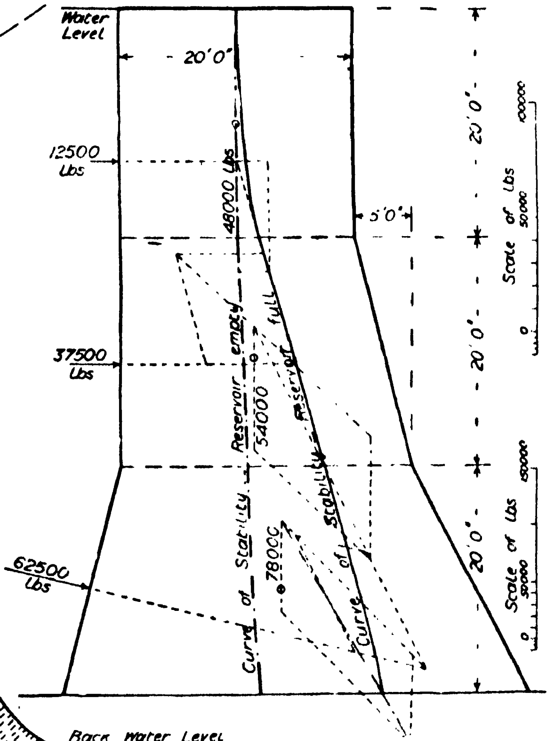
Everyone knows by personal experience that an overturning pressure may be most easily resisted by leaning against it, and the principle holds equally well with retaining walls. A wall to resist the pressure of earth will need less bulk in proportion as it can be leaned against the earth. The reason is that the centre of gravity is thrown further back, so that the weight of the wall acts with greater leverage. The usual form of section is shown in **221**, and the mode of working to ascertain the stability is indicated by the dotted lines. A given section has first to be assumed and then its stability determined. The line indicating the natural slope according to the material is put on at the back of the wall, starting at the level of the horizontal section where the stability is to be determined. Then the angle between the natural slope and the vertical is bisected to give



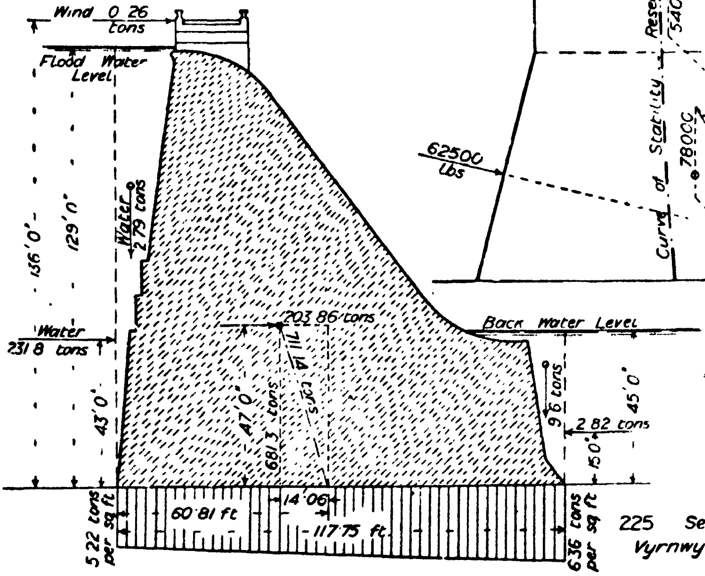
222 Surcharged retaining wall



223 Retaining loaded at back



224 Principle of calculating dam



225 Section of Vyrnwy dam

the line of rupture; this may be considered as the line of fracture of the earth if the wall should overturn, or the primary angle at which the earth would stand unsupported, the natural slope being the ultimate angle after long exposure to the weather. The wedge of earth between the line of rupture and the back of the wall may be considered to press against the wall without friction. Its centre of gravity must be determined and its weight calculated, then, dropping a vertical line from the centre of gravity to meet the line of rupture, a length is measured upwards to any given scale to represent the weight of one foot run, and from the top of this measurement a line is drawn parallel to the line of rupture to cut a horizontal line from the junction with the line of rupture. The horizontal length so cut off gives the thrust upon the wall at one-third of the total height. Now, the centre of gravity of the wall must be found and the weight of one foot run calculated; then the thrust of earth and the weight of wall are combined by the parallelogram of forces to give a resultant, which in this case cuts the base at a distance of 0·416 ft. from the outer edge. By the formula $\frac{2}{3}\cdot\frac{W}{d}$ the maximum intensity of pressure upon the outer edge of base is found to be 0·9 ton per foot super.

Surcharged Retaining Wall. When the earth rises higher than the wall by reason of a sloping bank above it, the wall is said to be surcharged. Such a wall is shown in **222**, and the method of finding the thrust is as follows. Having drawn to scale the assumed section of wall and the earth at back, produce the line of slope of surcharge indefinitely through the wall, and from point A set out the angle θ equal to the natural slope of earth. Produce this line to cut the continuation of slope of surcharge in point B, then the horizontal thrust in pounds at point C, which is one-third the height of back of wall, will be $\frac{1}{2}w(AB)^2$, where w = weight of earth in pounds per cubic foot, and AB = length in feet, then $\frac{1}{2} \times 112 \times 9\cdot8^2$ = say, 5,380 lb. set out as CD. Next, from D draw a vertical line and from C draw a line parallel to the natural slope to cut this vertical in point E, then CE will be the thrust on back of wall and will be found to equal about 6,550 lb. Producing this in the usual way and combining with weight of one foot length of wall, the resultant will be found to cut the base at a distance of 1·1 ft. from point F, then by the formula

$$\frac{2}{3}\cdot\frac{W}{d} = \frac{2\times8800}{3\times1\cdot1} = \text{say, } 5330 \text{ lb.,}$$

or about 2·4 tons per square foot maximum compression on the wall.

Retaining Wall Loaded at Back. When a warehouse is built on the earth at the back of a retaining wall, or a large crane is fixed there, or a line of rails on a roadway runs near, the thrust upon the wall will be increased beyond that due to the weight of the wedge of earth. An approximate method of finding the thrust in such a case is shown in **223**. The difference from **221** is that an additional thrust due to the external load has to be combined with the ordinary thrust as follows: From the point of application A of the external load nearest the wall draw a line parallel with the line of rupture to cut the back of the wall in the point B, and from B set out BC horizontal, so that the point C is directly under the point A; next set up CD equal to the load on point A and make DE parallel with the line of rupture, then CE will be the amount of thrust due to load A acting on the back of wall at point B. Combining this with the weight of wall acting through its centre of gravity will give the first resultant, FG. Next, find the horizontal thrust due to the wedge of earth acting at one-third the height of back of wall and combine with FG, giving the second resultant, HJ. Then, treating the other load on the surface in exactly the same way as the load at point A, the horizontal thrust acting at point K will be LM, and combining this with the second resultant, HJ, the final resultant, NO, will be obtained, cutting the base of wall at a distance of 0·9 ft. from the toe P, when, by the formula

$$\frac{2}{3}\cdot\frac{W}{d} = \frac{2\times72}{3\times0\cdot9} = \frac{144}{2\cdot7} = 53\cdot3 \text{ cwt.,}$$

or, say, 2·66 tons per square foot maximum compression on the brickwork.

Reservoir Wall or Dam. When a wall has to support the pressure of water the same method of working as in **221** might be adopted, taking the natural slope as zero; but it is more usual simply to calculate the pressure normal to the back of wall at one-third the height as $\frac{1}{2}wh^2$, where w = 62·5 lb., the weight of a cubic foot of water, and h = the height of wall. For high walls the material is economised by using a curved batter, so that the resultant of thrust passes through the extremity of the middle third at every horizontal section. A dam is shown in **224** in three simple stages to illustrate the mode of working to ascertain the stability. For a plain wall with straight batter the thickness at base may be approximately seven-tenths of the height. The section of the Vyrnwy dam is shown in **225**, with particulars of the loads and thrusts. This is of special interest owing to its magnitude and the successful manner in which the whole of the works were executed.

OFFICE-KEEPERS AND BOYS

Messengers, Office-keepers, Housekeepers and Attendants.
Boy Clerks and Messengers: Examination and Remuneration

NATIONAL SERVICE
continued from
page 2574

By ERNEST A. CARR

POSTS as messenger, office-keeper, housekeeper, and attendant are usually filled without competition by candidates who obtain the requisite official nomination. The right to nominate is generally vested in the head of each department; but in some instances it is in the hands of the Lords of the Treasury. The limits of age for these appointments are 21 and 35, but candidates who have served in the Army or Navy, the Metropolitan Police or the Royal Irish Constabulary, are allowed to deduct such service in reckoning their age. When a vacancy arises in a department, the person nominated has only, as a rule, to pass a qualifying examination of an elementary character before receiving the appointment. Occasionally, however, two or three men compete for a single vacancy. The subjects of examination are writing (with copying manuscript), spelling, and arithmetic, comprising the first four rules, money and avoirdupois weight.

Although a certain amount of influence, direct or indirect, is almost indispensable for securing a situation of this class, it is by no means necessary that the applicant should be personally known to the official who has the right to nominate. Character, ability, and a good record are as least as important. Satisfactory service in the Army or Navy is always a strong recommendation to the nominating authority. During the last year on the records, out of 290 vacancies for messengers in various Government offices, no fewer than 122 were filled by ex-soldiers and ex-sailors.

Rates of Pay. The salaries of subordinate officers vary a good deal, and in certain instances are augmented by "perquisites" whose value is a jealously guarded secret. The following rates may, however, be regarded as typical. Messengers and attendants commence at a figure between £65 and £80, and rise by small increments to £100, £120, or (for chief posts) £150 to £200 a year. They have also chances of advancement to the grade of office-keeper, with a salary of £100 or £150, an official residence, coal and lights, and other allowances on a liberal scale. Door-keepers are similarly remunerated as a rule, but in important positions (as in the Houses of Parliament) they receive from £250 to £300 a year.

BOY CLERKSHIPS

The position of boy clerk in the public service is a purely temporary one, carrying no claim to superannuation, and coming to an end when the age of twenty is reached. Nevertheless, this is in several respects a distinctly useful way of gaining a footing in the service, and, considering the overcrowded state of the commercial labour market, it is surprising to find that in recent years the number of qualified candidates has not always been equal to the demand, and that very moderate marks are needed for success at any of the competitions for appointments.

We have already referred to some of the advantages afforded to boy clerks when competing for the higher posts. Not only in the examinations for Second Division clerkships, but also in those for port service clerks and assistants of Customs and Excise, they may claim both service marks and a deduction from their actual age, even though at the time of the examination they are no longer in the service. For the Excise competitions this allowance is one year, and in the other cases two years. With such aids to success, a lad of ordinary ability and energy can scarcely fail to obtain a good permanent appointment, and at the worst an assistant clerkship is not altogether to be despised.

Competitions open to boys between 15 and 17 years of age are held about thrice yearly, a batch of some two or three hundred candidates being selected on the results of each. For the convenience of competitors, the examinations are held simultaneously at a number of centres—usually in London, Edinburgh, Dublin, Bedford, Bristol, Liverpool, Southampton, Aberdeen, Glasgow, Belfast, and Cork. A fee of 5s. is payable by each candidate.

Particulars of the subjects are furnished by the accompanying table. It relates to an examination recently attended by 800 contestants, 261 of whom were placed on the register of boy clerks and given employment as occasion arose.

EXAMINATION FOR BOY CLERKSHIPS

Order of Merit.	Handwriting and Orthography.	Arithmetic.	English Composition.	Copying Manuscript.	Any two may be taken.							Total.
							Translation from					
					Geography.	English History.	Latin.	French.	German.	Mathematics.	Chemistry and Physics (rudiments).	
Max.	400	400	400	200	400	400	400	400	400	400	400	2,200
1	363	346	340	188	326	—	—	335	—	—	—	1,898
261	355	256	202	125	338	—	—	—	—	75	—	1,351

Examination Subjects. The papers set at this competition were typical of their class. The exercise in copying manuscript was long but fairly easy. Candidates were given two simple passages of about equal length to be transcribed in three-quarters of an hour, all abbreviations having to be written out at full length, and the punctuation corrected where necessary. The test in orthography was a curious one, consisting of a fable taken from some ancient work and preserving the antique mode of spelling. We quote a typical portion of the story: "The fellowe that profest him friendeshippe, tooke to his feete and ranne and climmed up to the top of a hye tree. The straunger perceyving that his friende was fledde, and he himselfe not able to escape, fell downe unto the grounde; for it is sayde that the Lion and the Beare will spare their yeelded praies, and specially the Beare, if a man hold hys breth as though he were deade." Of this narrative a copy had to be made, putting all the words into modern spelling, but making no other changes.

The exercise in English composition comprised, in addition to a short essay, the perusal of a long passage in prose and verse—the adventure of Childe Rowland with the King of Elfland—which each candidate had then to narrate in substance in his own words, and as far as possible in his own way. The arithmetic paper included the following curious test of each candidate's ability to use a rule, as well as his grasp of mathematical principles: "Measure in centimetres the length and diameter of the block supplied. If the length of such a block is l cm. and the diameter d cm., it is known that the volume is $0{\cdot}79 \times l \times d \times d$ cubic centimetres. Use this to find the volume of the block."

It is necessary only to add that the mathematics paper in these contests comprises Euclid, Books I. and II., and algebra up to simple equations, and that no subjects are obligatory, but that a qualifying total of half the maximum marks must be obtained. In the contest to which our table relates, 544 candidates reached that standard, being in the proportion of only about two qualified competitors for each place.

Pay and Conditions of Service. Boy clerks are usually engaged for 39 hours weekly, and are paid during their first year 15s. a week, 16s. the next, and so up to the maximum of 19s. Overtime work is paid for at corresponding rates. Sometimes they are employed and paid by the hour instead, the rate being 4½d. per hour during the first year, and advancing yearly by a halfpenny per hour to 6d. As a little calculation shows, under this system of payment the net result is practically the same as under the weekly scale. In either case continual service is not officially guaranteed. The method of employment, according to the regulations, is as follows. A register of boy clerks is kept by the Civil Service Commissioners, and candidates declared successful at the competitions have their names placed upon it. As vacancies for boy clerks arise in the various public departments, those who are on the register are summoned to attend for duty, on the understanding that the work may prove only temporary, and that they will not be paid except while actually engaged by the department. As a matter of practice, however, the great majority of boy clerks are regularly employed. They are almost always called upon to serve in London, but recently a separate register has been instituted for appointments in Ireland, and at the last examination 20 vacancies were announced as Irish.

Boy clerks, when employed, are paid for all public holidays, as well as during the fortnight's annual leave to which they are entitled if permanently on duty. Sick leave, up to a certain maximum, is granted on three-fourths of full pay. In case of enforced absence, owing to infectious disease in the boy clerk's residence, he may be given the full rate of pay during his absence.

Prospects for Boy Clerks. As an incentive to him in preparing for the examinations admitting to permanent appointments in the service, there is a further and valuable provision that a boy clerk who obtains leave from the head of his department in order to attend an open competition for Second Division clerkships, or for assistant clerkships, may receive full pay while attending the contest.

In view of the advantages already discussed and the useful training in Civil Service subjects which these examinations afford, a youth who must earn his own living and has his way to make in the service could scarcely make a better start than in the modest capacity of a boy clerk. And unless he is sadly wanting in ability and application, he should not find the least difficulty in obtaining an appointment, there being —as we have shown—no serious competition for such posts.

BOY MESSENGERS

A register of temporary boy messengers for employment in Government offices is kept by the Civil Service Commissioners, and lads of good health and character, between 14 and 16 years of age, who have passed Standard V. in an elementary school or can pass a test in reading and writing, may apply to be registered. They are then eligible for service as occasion arises, and while employed are paid 9s. a week, rising by 1s. 6d. a week for each year's service up to the age of 20, when their names are removed from the register. As well-paid work of a light and pleasant nature, boy messengerships are in considerable request, and from time to time it becomes necessary to suspend registration for a while until employment has been found for the lads already on the register.

ALGEBRAIC EQUATIONS

Problems Leading to Simple Equations with One Unknown Quantity. Problems Leading to Simple Simultaneous Equations

By HERBERT J. ALLPORT, M.A.

PROBLEMS LEADING TO SIMPLE EQUATIONS

51. By the aid of Algebra we are able to solve problems the solutions of which by Arithmetic are either impossible or very laborious. We have simply to express the conditions of the question in algebraical symbols. This gives us one or more equations, the roots of these equations being the unknown quantities which the problem requires us to find.

We shall first consider problems in which there is only *one* unknown quantity, and in which the conditions of the question lead to a simple equation—*i.e.*, an equation of the first degree.

Example 1. The difference between two numbers is 5; if 2 be added to the greater, the result is twice the smaller. Find the numbers.

Here, although we have to find *two* numbers, we may still consider the problem as containing only *one* unknown quantity. For, if we can find, say, the greater of the two numbers, we obtain the other by subtracting 5. Suppose, then, that

$$x = \text{the greater number.}$$

It follows that

$$x - 5 = \text{the less number.}$$

Now, the question tells us that if we add 2 to the greater number, the result is twice the

But, by adding 2 to the greater number we obtain $x + 2$, and twice the less number is $2(x - 5)$.

Hence we have the equation

$$x + 2 = 2(x - 5).$$

Removing the brackets, and transposing the terms, we get

$$2x - x = 2 + 10;$$

or,

$$x = 12.$$

Thus, the greater of the two numbers is 12, and the other number is $x - 5$, *i.e.*, $12 - 5$, or 7.

Example 2. The sum of £8 12s. 6d. is paid with 30 coins, some of which are half-crowns, and the rest are half-sovereigns. How many are there of each sort?

Let x = the *number* of half-crowns.

Then, since there are 30 coins altogether, the number of half-sovereigns must be $30 - x$.

We have now to express algebraically the fact that x half-crowns and $(30 - x)$ half-sovereigns make a total of £8 12s. 6d. We must be careful in forming our equation that all the quantities involved are expressed in terms of the same unit. In this particular case it is convenient to work in half-crowns.

We know that a half-sovereign equals 4 half-crowns.

Therefore,

$(30 - x)$ half-sovereigns equal $4(30 - x)$ half-crowns.

Also, £8 12s. 6d. equals 69 half-crowns. We have, then, simply to write down the statement algebraically that x half-crowns and $4(30 - x)$ half-crowns make 69 half-crowns. Thus

$$x + 4(30 - x) = 69.$$

Solving this equation in the ordinary way, we find that $x = 17$, and therefore $30 - x = 30 - 17 = 13$. Thus the solution of the problem is that there are 17 half-crowns and 13 half-sovereigns.

Example 3. A has as many florins as B has half-crowns. If B gives A two of his half-crowns they will then have equal amounts of money. How much had each at first?

Let x = the *number of coins* each has at first. When B has given A two half-crowns, B will have $(x - 2)$ half-crowns, and A will have x florins + 2 half-crowns.

Expressing the values in sixpences, we see that B has $5(x - 2)$ sixpences (for 5 sixpences make half-a-crown), and A has $(4x + 10)$ sixpences.

Hence,

$$5(x - 2) = 4x + 10.$$

The solution of this equation is

$$x = 20.$$

Therefore,

A had 20 florins, or £2,
B had 20 half-crowns, or £2 10s.

Example 4. A man's age is 38, his son's is 16. When was the father 3 times as old as the son?

Let x = number of years which have passed since the father was 3 times as old as the son.

Then, x years ago the father's age was $38 - x$, and the son's was $16 - x$, so that

$$38 - x = 3(16 - x).$$

This gives $x = 5$, so that the required solution is, 5 years ago.

Example 5. A number consists of two digits whose sum is 9. If the digits be interchanged, the number so formed exceeds the original number by 45. Find the number.

Let x = the digit in the units' place.

Then, since the sum of the digits is 9,

$$9 - x = \text{the digit in the tens' place.}$$

Probably, the beginner's only difficulty will be in writing down the number. But he has only to think of the meaning of a number expressed in the ordinary notation.

The number 37, for example, means 3 tens + 7 units. In the same way, then, if $(9-x)$ stands for the tens' digit, and x for the units' digit, the value of the number is

$$(9-x) \text{ tens} + x \text{ units},$$

i.e.,

$$10(9-x)+x.$$

Similarly, if the digits are interchanged, the number obtained will be

$$10x+(9-x).$$

The question tells us that the second of these exceeds the first by 45.

Hence,

$$\{10x+(9-x)\}-\{10(9-x)+x\}=45.$$

Solving this equation, we obtain $x=7$. Thus, the units' digit is 7, and the tens' digit is $9-7$, *i.e.*, 2. The required number is, therefore, 27.

EXAMPLES 9

1. Find two numbers whose sum is 63 and whose difference is 7.

2. Find the number which, when multiplied by 3, is as much above 18 as it was originally below 18.

3. Divide 39 into two parts such that twice one part is 2 less than three times the other.

4. Divide 69 into three parts such that the first shall be double the second, and the second be 3 more than thrice the third. [Let $x=$ the third part.]

5. Find a number such that the product of one more than its double and one less than its half may be 10 less than its square.

6. A father's age is three times his son's age. In 12 years the father will be twice as old as the son. What are their present ages?

7. The united ages of three sisters make 47. The youngest is 3 years younger than the second, and the second is 5 years younger than the eldest. How old are they?

8. A sum of money is divided between A, B, and C, so that A and B have £39 between them, B and C have £26, and A and C have £31. Find the amount each has.

9. There are 81 coins, of which some are crowns and the rest are shillings. If the crowns were florins and the shillings were half-crowns, the total value would be unaltered. Find the number of coins of each sort.

10. If 12 oranges cost as much over 10d. as 20 cost under half-a-crown, how many oranges can be bought for five shillings?

11. Of two squares of carpet, one measures 16 feet further round than the other, and contains 64 square feet more in its area. Find the length of the side of each square.

12. A purse contains 26 coins, whose total value is £6. A certain number of the coins are sovereigns, there are three times as many half-crowns, and the rest are shillings. How many coins are there of each sort?

13. If A gave B ten shillings he would have three times as much as B; while if B gave A five shillings, A would have four times as much as B. How much has each?

14. Find three consecutive numbers whose continued product is 5 less than the cube of the middle number.

15. A number of two digits is such that one digit is three times the other, and if the digits be interchanged the number so formed exceeds twice the original number by 10. Find the number.

PROBLEMS WITH TWO UNKNOWN QUANTITIES

52. We will now consider problems with *two* unknown quantities involved. Many of the questions already given did, as we saw, contain two unknown quantities, but they were of such a nature as enabled us to form an equation containing only *one* unknown. Even when this is possible the work is often simplified if we take two unknowns, and from the conditions of the question form two equations.

Example 1. 6 lb. of tea and 8 lb. of sugar cost 11s. 2d., and 5 lb. of tea and 2 lb. of sugar cost 8s. 4d.; find the cost of each per lb.

Let

$x=$ cost of 1 lb. of tea, *in pence*

and

$y=$ cost of 1 lb. of sugar, *in pence*.

[NOTE. Always be careful to state exactly what the unknown quantities x and y are intended to represent. They will, of course, always stand for *numbers*, but it must be made clear whether it is a number of *pence*, or *shillings*, or *miles*, as the case may be. Such a statement as "Let $x=$ price of 1 lb. of tea" is much too vague.]

Therefore 6 lb. of tea cost $6x$ pence, and 8 lb. of sugar cost $8y$ pence. The total cost is thus $(6x+8y)$ pence. But the question tells us that the cost is 11s. 2d., or 134 pence. Hence,

$$6x+8y=134. \quad . \quad . \quad . \quad (1)$$

In the same way, since 5 lb. of tea and 2 lb. of sugar cost 8s. 4d., we have

$$5x+2y=100. \quad . \quad . \quad . \quad (2)$$

By solving (1) and (2) we obtain

$$x=19,\ y=2\tfrac{1}{2}.$$

Thus, 1 lb. of tea costs 19d., or 1s. 7d., and 1 lb. of sugar costs 2½d.

The above problem is an example in which, although it is not *necessary* to use two unknown quantities, the work is simpler if we do so. Using only one unknown, the problem would be solved as follows:

Let

$x=$ cost of 1 lb. of tea, in pence;

then $6x$ pence $=$ cost of 6 lb.

But 6 lb. of tea and 8 lb. of sugar cost 134d.

Therefore 8 lb. of sugar cost $(134-6x)$ pence; or,

$$\frac{134-6x}{8} = \text{cost, in pence, of 1 lb. of sugar.}$$

Hence, since 5 lb. of tea and 2 lb. of sugar cost 100 pence, we have

$$5x+\frac{2(134-6x)}{8}=100.$$

The solution of this gives $x=19$. The cost of the sugar is then obtained by substituting the value of x in the expression

$$\frac{134-6x}{8}.$$

Example 2. The wages of 7 men and 11 boys for a day amount to £2 1s., and 2 men receive 6d. less than 5 boys. Find the daily wages of a man.

Let

x = number of shillings a man earns per day, and

y = number of shillings a boy earns.

Then 7 men and 11 boys will earn $(7x + 11y)$ shillings.

Therefore,

$$7x + 11y = 41. \quad . \quad . \quad . \quad (1)$$

Again, $2x$, the amount earned by 2 men, is 6d. less than $5y$, the amount 5 boys earn; so that $2x$ shillings and $\frac{1}{2}$ shilling make $5y$ shillings.

Therefore,

$$2x + \tfrac{1}{2} = 5y. \quad . \quad . \quad . \quad . \quad (2)$$

Clearing (2) of fractions, and transposing, we have

$$4x - 10y = -1. \quad . \quad . \quad . \quad (3)$$

Multiply (1) by 10 and (3) by 11, and add. Then

$$70x + 44x = 410 - 11 ;$$

or,

$$114x = 399$$

Therefore,

$$x = 3\tfrac{57}{114} = 3\tfrac{1}{2} \text{ shillings.}$$

Hence, a man's daily wage is 3s. 6d. *Ans.*

Example 3. A has three times as many shillings as pennies, and B has three times as many pennies as shillings. If A has 7d. more than B, and together they have two more pennies than they have shillings, how much has each?

Let

x = number of pennies A has;

then

$3x$ = number of shillings A has.

Similarly, if

y = number of shillings B has,

then

$3y$ = number of pennies B has.

We obtain one equation from the fact that, together, they have 2 more pennies than shillings. Thus,

Total number of pennies = $x + 3y$,

and,

total number of shillings = $3x + y$.

Therefore,

$$x + 3y = 3x + y + 2 ;$$

or, transposing, and dividing by 2,

$$x - y = -1. \quad . \quad . \quad . \quad . \quad (1)$$

We obtain the second equation from the *values* of the sums of money A and B have. Thus, A has x pennies and $3x$ shillings, that is $(x + 36x)$ pence, in value. Similarly, B has $(12y + 3y)$ pence, in value. Hence,

$$x + 36x = 12y + 3y + 7 ;$$

or.

$$37x - 15y = 7. \quad . \quad . \quad . \quad (2)$$

Multiply (1) by 15 and subtract from (2). Then

$$37x - 15x = 7 + 15 ;$$

or,

$$22x = 22.$$

Therefore,

$$x = 1.$$

Hence A has 1 penny, and, consequently, 3 shillings. His total is thus 3s. 1d. This, the question tells us, is 7 pence more than B has, so that B's total is 2s. 6d.

Example 4. A number of three digits has its tens' digit double of the units' digit. It exceeds by 99 the number formed by reading the digits backwards, and the sum of these two numbers is 585. Find the original number.

Let

x = digit in the units' place;

then

$2x$ = digit in the tens' place.

Let

y = digit in the hundreds' place.

Then the number is $100y + 20x + x$. [Compare Art. **51**, Ex. **5**.] If the digits are read backwards, x becomes the hundreds' digit, $2x$ the tens' digit, and y the units' digit. The number is then $100x + 20x + y$. Hence,

$$(100y + 20x + x) - (100x + 20x + y)$$
$$= 99 ; \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and

$$(100y + 20x + x) + (100x + 20x + y)$$
$$= 585. \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Collecting terms, we get from (1)

$$99y - 99x = 99 ;$$

or,

$$y - x = 1. \quad . \quad . \quad . \quad . \quad (3)$$

and, from (2)

$$141x + 101y = 585. \quad . \quad . \quad . \quad (4)$$

Solving (3) and (4) we find $x = 2$, $y = 3$.

Hence, the units' digit is 2, the tens' digit is twice 2, and the hundreds' digit is 3.

The required number is thus 342 *Ans.*

EXAMPLES 10

1. Find two numbers such that their sum is less by 2 than five times their difference, and three times the greater exceeds four times the less by 7.

2. In another year a father will be four times as old as his son; 2 years ago he was three times as old as his son will be in another 3 years. Find their present ages.

3. A number of two digits exceeds 5 times the sum of the digits by 7, and exceeds by 9 the number formed by reversing the digits. Find the number.

4. A, B, C, and D have £100 amongst them. C has twice as much as A, and B has three times as much as D. Also, C and D together have £2 10s. more than B. How much has each?

5. In 2 years' time a father will be three times as old as his elder son, and five times as old as his younger son. In 23 years' time his age will be equal to the sum of his sons' ages. How old is each of them now?

6. In 8 hours A walks 8 miles more than B does in 5 hours, and in 9 hours B walks a mile

more than A does in 10. How many miles does each walk in an hour?

7. A and B have a guinea between them. If A gives B a shilling for every penny B has, A will have 5s. less than B. How much has each at first?

8. A takes 5 hours more than B to go a distance of 60 miles. If A had doubled his pace he would have taken 5 hours less than B. Find the rate at which each travelled.

Answers to Algebra

EXAMPLES 7

1. $x = 2$. 2. $x = -\frac{1}{4}$. 3. $x = 12$.

4. Multiply both sides by 6, obtaining $3x - 6 - 2x - 8 = 5x - 2$, whence $x = -3$.

5. $3(x^2 + 2x + 1) + 4(x^2 - 6x + 9) = 7(x^2 - 2x + 1)$.

Therefore,

$$6x - 24x + 14x = -3 - 36 + 7;$$

giving

$$x = 8.$$

6. Multiply by 12. Then $6(x + \frac{1}{4}) - 3(3x - \frac{1}{4}) = 4(x - \frac{3}{4})$, so that $6x - 9x - 4x = -3 - \frac{3}{4} - \frac{6}{4}$. Therefore $-7x = -\frac{21}{4}$ and $x = \frac{3}{4}$.

7. $x = 1$.

8. $(x + a + x + b)(x + a - x - b) = (a - b)^2$ [Art. 34], or $(2x + a + b)(a - b) = (a - b)^2$. Divide both sides by $(a - b)$. Then $2x + a + b = a - b$. Whence $x = -b$.

9. Multiply both sides by x. Then $a + b = cx(a + b)$. Divide both sides by $(a + b)$, and we get $1 = cx$, or $x = \frac{1}{c}$.

10. Removing brackets [Arts. 33 and 31] we have

$$\begin{aligned} &x^3 + 3ax^2 + 3a^2x + a^3 \\ &+ x^3 + 3bx^2 + 3b^2x + b^3 \\ &+ x^3 + 3cx^2 + 3c^2x + c^3 = 3x^3 + 3x^2(a + b + c) \\ &\qquad + 3x(bc + ca + ab) + 3abc. \end{aligned}$$

Collecting terms, $3x(a^2 + b^2 + c^2 - bc - ca - ab) = -(a^3 + b^3 + c^3 - 3abc)$.

Divide both sides by $3(a^2 + b^2 + c^2 - bc - ca - ab)$ [Art. 42, Ex. 2] and we get

$$x = \tfrac{1}{3}(a + b + c).$$

EXAMPLES 8

1. $x = 5$, $y = 3$. 4. $x = 3\frac{3}{8}$, $y = \frac{3}{4}$.
2. $x = 3$, $y = -4$. 5. $x = y = 5$.
3. $x = 3$, $y = 2$. 6. $x = 4$, $y = 8$.

7. Since $\frac{x}{15} + \frac{y}{12} = 1$, we have $4x + 5y = 60$. And since $\frac{x}{3} - \frac{y}{4} = 1$, we have $4x - 3y = 12$. Hence, $x = 7\frac{1}{2}$, $y = 6$.

8. Multiply first equation by 10, giving $5x - 5y - 6x + y = 5$, or $x + 4y = -5$. Multiply second equation by 6, $2x - 3y = 12$. Hence, $x = 3$, $y = -2$.

9. Solve for $\frac{1}{x}$ and $\frac{1}{y}$, obtaining $\frac{1}{x} = \frac{1}{2}$, $\frac{1}{y} = -1$. So that $x = 2$, $y = -1$.

10. Solve for x and $\frac{1}{y}$. Solution is $x = 4$, $y = 1$.

11. $x = y = a - b$. 12. $x = a$, $y = b$.

13. Add the three equations together, $2x + 2y + 2z = 20$. Therefore, $x + y + z = 10$. Subtract each equation in turn from this, and we obtain $x = 3$, $y = 5$, $z = 2$.

14. $x = -3$, $y = 1$, $z = 3$.

15. Add first two equations, giving $\frac{2}{x} = 4$. Hence, $x = \frac{1}{2}$. Substitute in second and third equations, and we get $\frac{1}{y} - \frac{1}{z} = -2$, and $\frac{1}{y} + \frac{1}{z} = 10$. Whence $y = \frac{1}{4}$, $z = \frac{1}{6}$.

NOTE. The answer to Algebra Examples 2, No. 5 [page 1994], should read "$-2ab$," etc.

PROSPECTING AND BORING

Searching for Minerals. The Discovery of Hidden Deposits. Electric Ore Finding. Boring and Blasting Tools and Practice

By D. A. LOUIS

THOSE who go in search of minerals, or, as it is called, *prospecting*, frequently go with a definite idea of looking for some special mineral for which a district has already some reputation. For instance, the Transvaal, the West Coast of Africa, Western Australia, would be prospected for gold; diamonds would be sought for in South Africa, Brazil, and India; the Ural Mountains for various minerals, including platinum. And in any region where active operations were in progress as much information as possible would be gleaned from the other workings, from maps and from published records—such, for instance, as those of our own Geological Survey—before undertaking fresh explorations. But any country, especially a new country, should be visited with an open mind and a keen outlook for the occurrence of any minerals that could be turned to good account, and their character should be carefully recorded.

Prospecting Possibilities. A noteworthy feature in the utilisation of mineral deposits is the element of uncertainty. A mineral of great value at one time may be of little value at another period. For example, silver mines in which the writer worked and which paid well in '87 will not pay now. Again, when he was working in Cornwall wolfram was a useless, troublesome constituent that was thrown away; now the requirements of commerce create a demand for it, and special works are profitably employed in Cornwall in extracting it. Once, a single mine working part of the year was sufficient to cover the world's requirements of pitch-blende; now it is eagerly sought for as a source of radium. Monazite was simply regarded as a scientific curiosity until Auer von Welsbach introduced the incandescent gas mantle made from some of its constituents, so that monazite sands are now extensively worked. Phosphatic fluxes, once scorned, are now in demand for iron smelting so as to produce a slag rich in phosphorus for use in agriculture.

When prospecting, the general aspect of the country, its water supply, its timber, and its geological character should first be observed most carefully.

An igneous country may be examined for basalts, granites, and such deposits, but it is useless to look for coal or any other stratified mineral deposit in such a neighbourhood. In a metamorphic country, all sorts of metallic treasures and many kinds of precious and ornamental stones may be expected, but, again, no coal or ordinary stratified deposits. In a stratified country, on the other hand, igneous rocks may occur, as, for instance, the bosses of crystalline rocks in Leicestershire, which project through Triassic strata; metamorphic rocks are likewise occasionally encountered in stratified regions.

Stratified Country. In a stratified country the order of superposition and the character of the rocks should be ascertained by inspecting any exposures and identifying any fossils; in this way the geological age of the deposit can be determined, and its possibilities of yielding mineral treasure predicted with some degree of certainty. Thus, if the exposures were Devonian in character, building stones, paving stones, and slates might be looked for. It would, however, be useless to search for Portland stone, or Bath stone, or coal in them or below them. With Lias beds exposed we might encounter hydraulic limestones, building stones, and below them coal, and so on.

Other observations should be made simultaneously, such as any pronounced colour of the soil or any staining of the rocks. Blackness might indicate coal or manganese; greens and blues, copper; ochreous patches, iron; red, iron, or even cinnabar; and so on. Vegetation should be noted, as some plants are addicted to certain kinds of rock; moreover, the presence of certain minerals in an otherwise fertile soil will cause sterility and vice versâ, so if change of vegetation or an area of barrenness be observed the cause should be investigated.

Ploughing and Animal Burrowing. Material thrown up by burrowing animals or exposed in digging or ploughing, and, of course, railway cuttings or any excavations, should be most carefully examined for the presence or indications of useful minerals. Fallen stones, especially those carried down by rivers, should be carefully inspected, and if any stones of a promising character, such as vein-rock, which are known as *shodes* or *shoad stones* be found, the inspection should be continued up the valley or river, and ultimately the source from which the stones have been derived may be found and a mineral vein discovered. This may be miles or only a few feet away.

From the prospector's points of view, a satisfactory feature about veins is that the vein-rock is generally of a different degree of hardness to the surrounding rock; usually it is harder, but occasionally it is softer, hence it is that, in weathering, the outcrop is marked by projecting masses of rock, or more rarely by depressions, which may generally be followed by the eye away across the country indicating the strike of the vein. These outcrops must be scrutinised most earnestly to see if they contain any useful minerals or indications of them. Should the outcrop have the appearance of a cellular, cindery, spongy-looking mass, deeply stained with dark and other hues of brown, it is the material known as *gossan*, and is generally a favourable indication.

In stratified deposits variable hardness is also indicated by the weathering; if hard, the exposed edge of more or less horizontal beds will form a steep face or *escarpment;* while, if soft, the face will be sloping. If the beds are more or less tilted, as they frequently are, then the softer beds will form the depressions, and the harder beds the projections and hills in the landscape. It often happens that patches of soft beds protected by resisting deposits remain as mounds, or even form earth pillars.

Discovering Hidden Deposits. It very frequently happens that the useful deposits of minerals are hidden from view. To discover them various practices are adopted. The position of any springs are noted and the character of the water investigated. Any mounds or heaps become the objects of particular solicitude, as they may prove to be the waste material from old mining and smelting operations, and an examination of the material would give useful information concerning the character of any deposit in the neighbourhood.

Probing. Probing is a simple means of search for shallow deposits; it consists simply of thrusting a sharp-pointed steel rod or wooden stick shod with iron or steel into the ground, and if the mineral sought be harder or softer than the surrounding soil its presence is detected by the feel. The position of shallow deposits of strontium mineral in Gloucestershire, of burrstones in France, and of phosphates in Carolina are disclosed in this way. The end of the rod may be examined for adhering mineral in the case of a deposit that could not be detected by the feel alone.

Hushing. Hushing is a method by which water is used to scour off the covering soil, and so expose any underlying, solid, hard deposit to view; the water for the purpose is collected in a reservoir, and directed by channels to the ground to be hushed.

Magnetic Search. In the case of deposits that affect a magnet, this instrument is used to indicate its presence. For this purpose both the ordinary compass and dipping needle are used. The deflections are noted, and from their intensity and direction large masses of buried iron ore have been discovered.

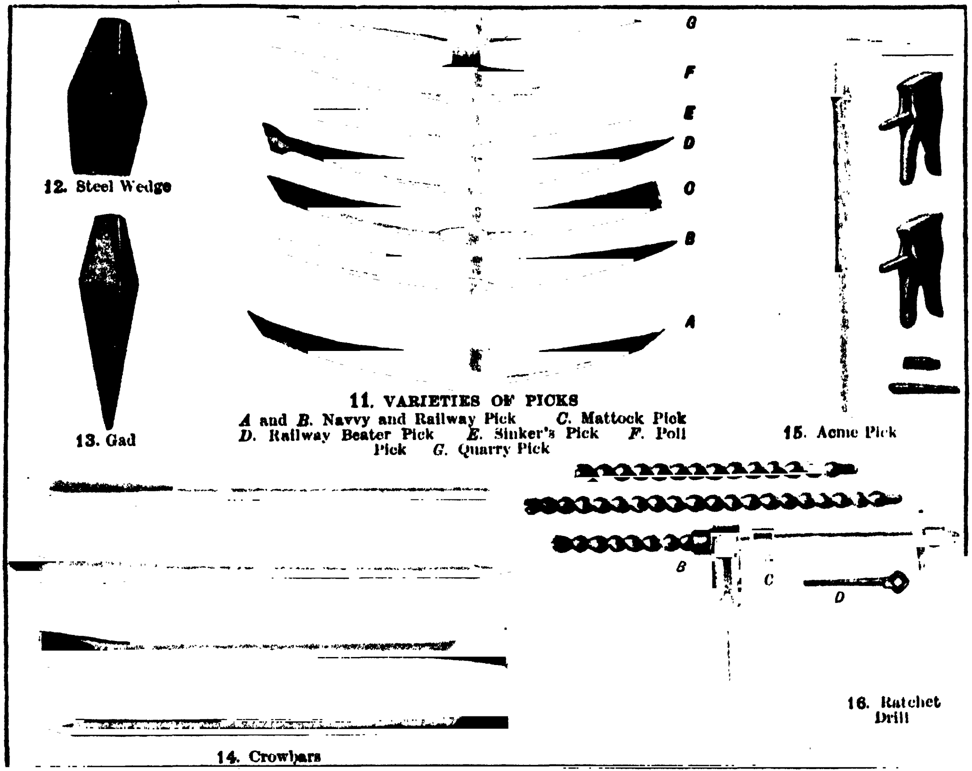
Electric Ore Finding. Electric ore finding has recently been introduced to aid in the discovery of useful mineral deposits. The system is based on the discovery made by Sir William Preece about 20 years ago that when the earth was energised with an interrupted current of low potential, the geological conditions of the earth's crust, through which the currents were flowing, altered the shape and changed the intensity of the field, which alterations could be detected by means of a telephone circuit connected to earth with portable electrodes.

This has taken a practical form for which Mr. Alfred Williams is responsible. He employs a portable battery, a transmitting apparatus, and a receiving circuit. And in use the transmitting electrodes are placed in the ground at 100 yd. apart. When the receiving electrodes are thrust into the ground within the field of influence, sounds can be heard from the attached telephones. These sounds vary with the character of the ground both in intensity and quality. The apparatus is worked by two operators, each with a receiving electrode, consisting of a steel rod 2 ft. long and a telephone; they alter the relative position of these electrodes in the field, and it is claimed that operators competent to detect and interpret the variations in the sound may find out the position, the size, and the character of a distant mass of mineral.

Boring. Portable hand boring appliances are used where deep-seated deposits are suspected, but at the stage to which reference is now being made—that is, the very first inspection of a country—it would be premature to embark on any deep-boring problem unless there were very good cause, such as geological evidence, or reliable records, for anticipating a valuable deposit lower down. But deposits to 50 ft. or so might be sought with a prospective boring kit, either percussive or rotary, to which reference will be made later.

It is exceedingly important to exercise great caution in the early stages of any mining enterprise; never entertain any costly outlay until sufficient good mineral is assured to yield a certain and ample profit on such outlay. Hence, if the search has furnished evidence of a promising deposit, that deposit must be proved to be good before incurring any heavy expenditure. It is advisable that the next operations should be conducted with due caution, and although devised so as to form part of a more extensive plan of work, they should at first be conducted on a moderate scale with simpler appliances with the sole object of rendering as much of the deposits accessible as possible. These operations make it possible to form a better judgment of deposit than can be gathered from the preliminary tests, and if it prove of less value than anticipated, and of a non-remunerative character, then no great loss will have been sustained, and the work may be abandoned without anguish. If, however, the deposit prove of value, these exploratory operations will be of immense value in deciding the character and magnitude of future operations, the amount of money that might reasonably be expended, and the kind of equipment that would be required to carry out the proposed work.

Proving Deposits. If the deposit be in the form of a well-exposed outcrop, it may be necessary only to clear away a certain amount of loose material, which can usually be done by picks, shovels, and wheelbarrows; and when a good face of stone, coal, or ore, as the case may be, has been exposed, some of it is broken down by means of a pick or by means of wedges or gads, or, better still, by blasting. A variety of picks are shown [11], while 12 is a steel wedge and 13 a steel gad. These operations are repeated at various spots indicated by the observations made while prospecting, and if the deposit comes up to expectations, it would then be necessary to see that there was a good supply of useful deposit, while its position is of paramount importance. Accessibility to road, railway, river, or other waterway is desirable, so is the provision of a suitable site to give plenty of room for working purposes, for the disposal of waste, and for the accommodation of necessary buildings and machinery. The investigation of the supply and cost of labour, fuel, mining-timber, and water, should also precede the systematic development of the prospect.



12. Steel Wedge

13. Gad

11. VARIETIES OF PICKS
A and *B*. Navvy and Railway Pick *C*. Mattock Pick *D*. Railway Beater Pick *E*. Sinker's Pick *F*. Poll Pick *G*. Quarry Pick

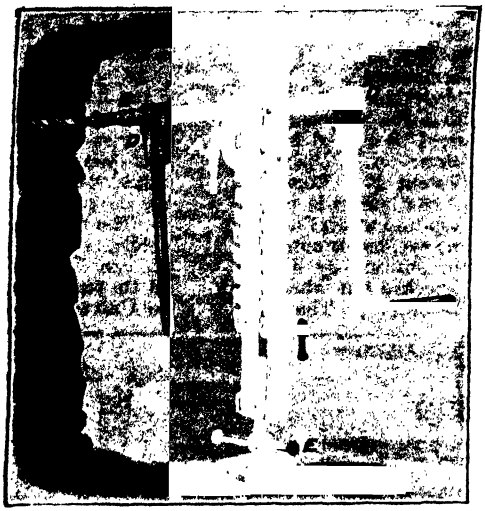
15. Acme Pick

14. Crowbars

16. Ratchet Drill

VARIOUS MINERS' TOOLS (Hardy Patent Pick Co.)

Implements for Proving Deposits. The *shovel* is used for excavating soft or loose ground, or for removing that broken up by other implements. The *crowbar* [14] is an iron lever which is used for prising off masses of stone or for shifting loose stones. The *pick* is a steel blade attached to a wooden handle, and used for breaking up ground. The blades [11] vary in form to suit the work, and are generally provided with an eye, into which the top of the handle is inserted and tightly wedged. The *pollpick* [11 F] has one pointed end and one flattened end, the latter for use as a hammer. Other picks have the ends forged to points or to chisel ends. The sharpening is done in the smithy. Various forms of picks are shown [11]. Sometimes it is convenient to have the blades readily detachable from the handles, so that for sharpening purposes the blades only need be carried backwards and forwards. The *Acme* and *Universal picks* of the Hardy Patent Pick Company are of this class. The Acme handle is provided with a socket at the top into which the blade passes. The blade has no eye, but is notched at the middle, and is held in position by a wedge, which can be easily knocked out when it is desired to remove the blade [15]. The handle of the Universal pick is larger at the top than at the lower end, and is provided with a spring socket [10, page 2380] at the upper end; the blade is furnished with an eye, and can be slipped up the handle, but it jams tightly on the larger end. When desired, however, it is easily removed by striking the small end on the ground. The picks shown [11], also the prospector's hammer, are of the Universal pattern. *Wedges* [12] with straight edges, or *gads* [13], which are pointed, are used to replace or supplement the pick in working out pieces of rock, and are used with a hammer or poll-pick. The implements just described suffice for many kinds of deposits, but when hard, dense rocks are encountered, or for fairly large bulks of



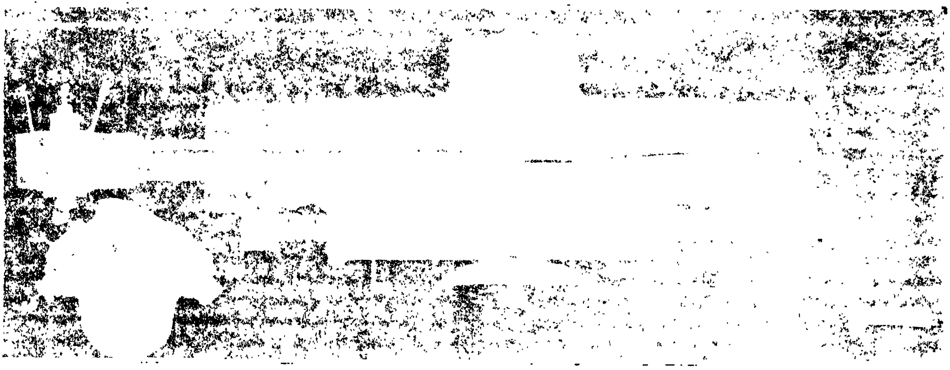
17. THE ELLIOT DRILL

softer rock, resort must be had to blasting, and for this purpose another set of tools comes into requisition.

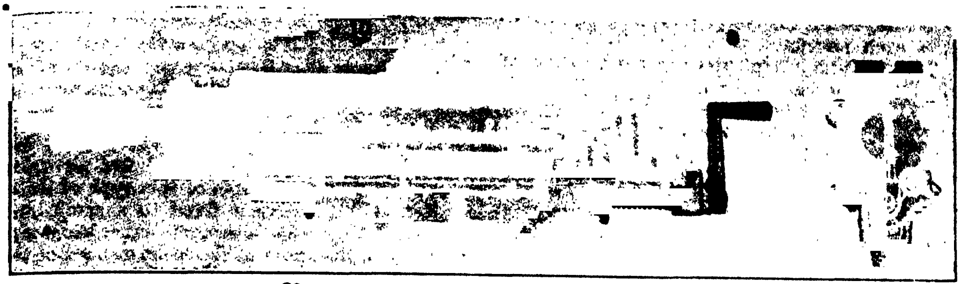
Blasting. Blasting is effected by making a hole in the rock, clearing it of dirt, putting a charge of explosive in the inner end, *stemming*, *packing*, or *tamping* the front part with clayey or other material, and igniting the charge by means of a fuse. The stemming prevents the escape of the products of the explosion; the force is therefore expended in rending the surrounding rock, which in consequence becomes shattered and fissured to a degree varying with the quantity and character of the explosive used. The shattered or fissured and fallen rock can then be removed by the use of the picks, shovels, etc. The holes are bored in soft rock by means of *drills* resembling *augers*; in hard rock by means of *jumpers*, or by *chisel drills* driven by *sledges* or *hammers*, or by rock drills.

Blasting Implements. *Jumpers* are iron bars with a swelling at the end or middle to give weight, and tipped with steel forged to a cutting edge. When used, the rock is usually notched with a blow or two of the pick, and then the jumper is struck repeatedly against the rock at that spot, being turned a little after each blow. In this way, a circular hole is made in the rock. Jumpers are made of different lengths, from a few feet up to ten or more, so that as the hole progresses longer jumpers are brought into use until the hole is sufficiently deep. In some situations jumpers, however, cannot be used; and also they would be very irksome and slow in very hard rock, so, under such crcumstances, and, as a matter of fact, in other cases too, drills come into use.

Drills are steel chisels. They chip the rock away like the jumper, but instead of giving the percussive blow by their own weight, they are held in the hand and given a blow with a sledge or hammer. When the miner guides the drill with one hand, and wields the hammer with the other, it is known as *single-handed drilling* [22]; when one guides and turns the drill while another gives the blow, it is known as *double-handed drilling*, which, naturally enough, is more rapid. A *scraper*, which consists of a disc of metal attached to a metal rod, is used to scrape the dust out of a bore hole. For muddy stuff, a *swabstick* is used. This consists of a wooden stick with the fibres at one end frayed into a kind of mop. A *charging spoon* is a half hollow cylinder of copper or zinc, with a wooden or copper handle, which is used for introducing loose gunpowder into horizontal, or nearly horizontal holes. The *tamping bar*, or *stemmer*, is a wooden, copper, or bronze rod with which the charge of explosive, frequently in the form of a cartridge, is thrust home. It serves, however, chiefly for ramming in the tamping to block up the front part of the hole, and is therefore grooved on one side to pass over the fuse in the hole without disturbing it. It must be made of material that, like copper, will not strike sparks when it comes into contact with the rock, as iron or steel would do. The *pricker* is another appliance which must fulfil this condition; it is a slender, tapering rod of copper or bronze, with a ring at the larger end. It is employed, when fuses are not used, for maintaining a passage in the tamping into which the *squib*, *rush*, *straw*, or what not can be inserted for firing the charge.



18. HOLMAN TAPPET VALVE DRILL



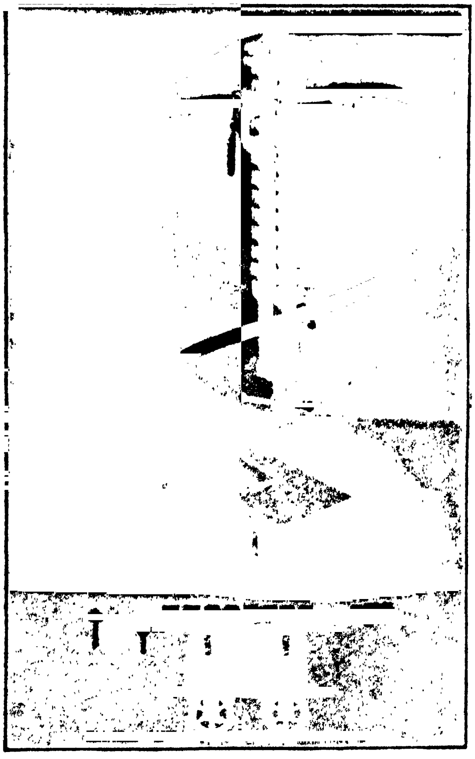
20. MARVIN-SANDYCROFT ELECTRIC DRILL

Mechanical and Power Drills. These drills are amongst the most important implements employed in quarrying or mining. With them holes can be drilled that could scarcely be contemplated by hand work, while even in ordinary drilling they are more rapid than hand work, especially in hard ground, where they can work five times as rapidly. Mechanical and power drills are either percussive or rotary, and there are a large number of good makers and good patterns; but it is possible only to mention a few types here.

Mechanical Drills. One of the simplest mechanical drills is the rachet drill [16]. It consists of an auger, A, inserted into a socket, B, attached to a feed screw which works in a nut, C, at the end of a long sheath, D. A ratchet, E, is fixed at the head of the auger, and by working the ratchet-handle the auger is turned, and at the same time the feed screw advances; the sheath is prevented from turning by allowing a pin, F, at the back end to jam against a piece of timber in the temporary support. When the feed screw has run out its full length it is run back, the use of a split nut at C facilitating this operation, and the auger can be replaced by a longer one. This drill is suitable for moderately hard work. The augers are made of twisted steel bar, which, to a certain extent, clears the hole itself.

The Elliot Drill. The Elliot drill [17] is another example of a mechanical drill of the auger type. The auger is inserted into a socket, D, on a feed screw, C, which, instead of working in a nut, works upon a worm-wheel held fast by an adjustable clamp, A. It is operated by moving a ratchet brace, D, backwards and forwards; this turns the feed screw and auger, and forces it into the rock; the clamp is adjusted to suit the hardness of the rock. When the feed screw has travelled to its full extent it is easily run back by loosening the clamp, and a longer auger is inserted before restarting. It will be observed that the drill can be placed at different heights on the stand, which can be tightened in position by the screw E.

Power Drills. For more expeditious work still, power is applied to working drills; compressed air, steam, water, petroleum, and electricity are all turned to account for this purpose, but the last three have not yet been extensively employed in mining. The simplest application of power to a drill is putting it to work on turning an Elliot drill, but the full advantage of power drilling is evinced in dealing with very hard rocks for which the auger drill would be unsuitable; in fact, machine drilling is done almost universally by percussive drills, which imitate the operations of hand drilling. They generally consist of a cylinder with a piston, which is given a reciprocating motion by compressed air; the cutting tool or chisel being firmly attached to the piston rod, deals a blow at each forward stroke. The turning of the drill at each stroke, to ensure a round hole, is usually effected by a rifled bar, and controlled by a ratchet wheel with pawls; the back end of the piston rod is hollowed out and provided with projections to fit the rifling of the bar, so it would turn during both the in and out stroke, but the pawls prevent the rotation in one



19. ELECTRICALLY DRIVEN ELLIOT DRILL
(Hardy Patent Pick Co.)

direction, hence the chisel gets the desired turn once each journey.

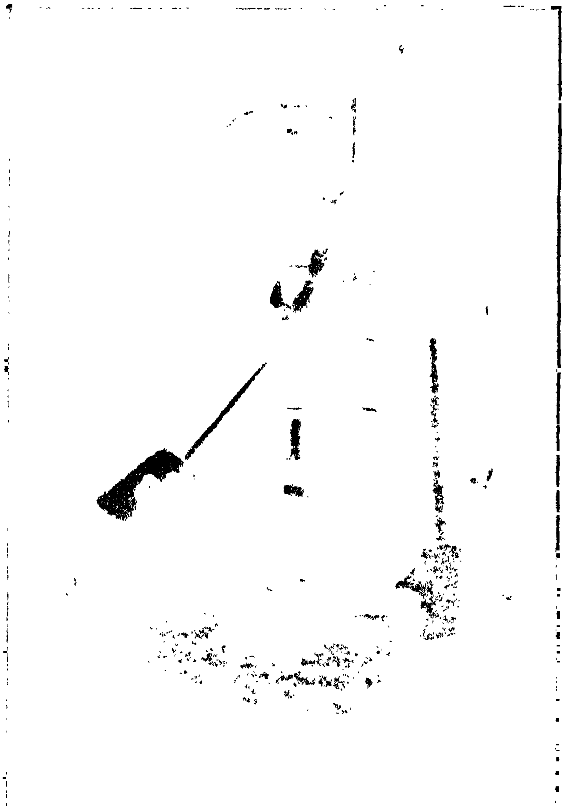
The machine is kept up to its work by means of a screw which works in a nut attached to the machine. A handle connected to the screw enables the man in charge to feed the drill forward upon the cradle which supports it; automatic feeding has also been employed, but is not much in favour. There are a very large number of types of these ingenious little machines, which vary mostly in the mode of working the valve. This is variously done—mechanically, by air pressure, by both these means combined, and by the use of an auxiliary valve to operate the main valve, while others have no valves at all—that is, the piston itself covers or uncovers admission or exhaust ports.

In the Civil Engineering course reference has been made to some rock drills, while the ordinary pneumatic caulking tool resembles in construction the drills of the third type. Hence, we need here notice only typical mining drills.

Drills with Mechanically Operated Valve. The Holman tappet valve drill is an example of this class [18]. It consists of a cylinder with two pistons connected together, but with a boss between them, which, when working backwards and forwards, sets a toppet rocking; and this works a valve of the ordinary D type so that the back and front part of the cylinder are alternately put into connection with the admission and exhaust ports. The exhaust is around the tappet into the cylinder between the pistons and thence to the atmosphere.

Drill with Valve Operated by Compressed Air. The Holman air valve drill serves as an example of this type of drill; in it the main valve is fixed to a spool, and is worked by the alternate exhaustion and charging of the space at the front or back of the valve chest, the alternation being effected by means of supplementary ball valves worked by the movements of the piston through the shoulders cut upon it for the purpose.

Drills with Valves Worked by Compressed Air and Mechanically. The Ingersoll-Serjeant auxiliary valve drill is an example of this class. The main valve is of the piston type, and, like other air-moved valves, is worked by the alternate exhaustion and charging of the back and front spaces of the valve chest; in this case this alternation is effected by means of a sliding valve made in the form of a segment of a circle and having a recess in one of its flat faces; it is slightly longer than its arc-shaped seat, so that one end of it always projects into the cylinder. The projecting end of this valve is caught by a shoulder of the piston as it passes, hence it is constantly being knocked backwards and forwards, and by reason of the recess putting one end of the valve chest in the other in connection with the exhaust.



21. WARSOP PETROL-DRIVEN ROCK DRILL (From the "Colliery Guardian")

Electricity in Drilling. Various electrically-driven drills have been introduced, and 19 illustrates the application of electricity to the Elliot drill, the flexible shafting from a motor taking the place of the ratchet braces. At the lower part of the figure it is shown packed up for transport.

Fig 20 illustrates the Marvin-Sandycroft electric drill, made by the Sandycroft Foundry Company, Ltd.

The drill consists of a solid steel plunger, surrounded by two coils of wire, through which electric currents are passed. The plunger or piston (1) is a solid steel forging, having an enlarged portion (2) which is surrounded by the coils of wire (3-3), and a shank (4) which passes through a bearing in the front head (5) of the machine, and is provided with a massive chuck, or tool holder (6), for holding the drill steel or bit. The magnetic pull of the coils (3-3) draws the plunger (1) backward and forward as the current alternately passes through them. The rifled ratchet rod (8) is provided with a ratchet wheel in the back head (9), and enters a rifled nut in the back part of the plunger. The cushion-spring (7) is of a very heavy helicoidal pattern. The function of this spring is to assist in checking the backward stroke of the plunger. It thus absorbs the surplus energy of the return stroke, and supplies the energy thus momentarily stored to the forward stroke. The coils which form the body of the machine are encased in a steel tube, and the front and back heads are drawn together by side bolts. A flexible cable, consisting of three wires, terminating in a connection which fits into a socket on the drill, leads the current to the machine, and connection to the wires of the coils is made by means of brass plugs extending through the case as shown by 10.

The plunger runs freely, having a bearing in the coils and in the front head of the drill. The shank of the plunger travels through a bronze bushing (11).

The drill is mounted upon an adjustable tripod, column, or stretcher-bar, as may be required.

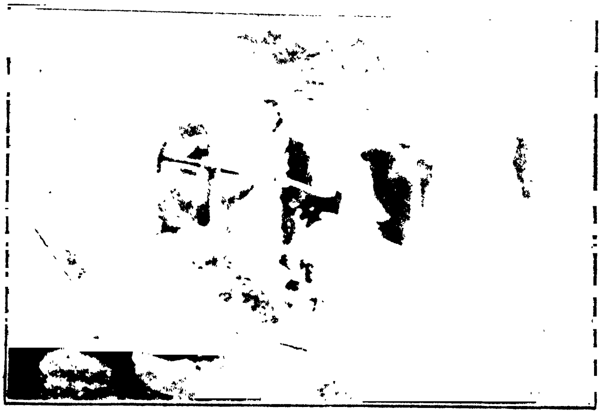
Petrol Drill. A drill driven by petrol is made by H. E. Warsop & Co., and is shown in 21. The power is conveyed from a petrol motor, not shown, by the flexible shafting, and is converted to reciprocating motion by suitable gear within the drill casing.

Rock Drill Supports. Whenever admissible, a simple tripod serves the purpose of a support. It consists of a strong steel frame, with telescopic legs for the sake of adjustment, and well weighted to ensure stability. Fig. 21 shows a form of tripod. But generally, in underground workings the drill is mounted on a standard or stretcher bar, which, by means of lengthening screws, can be fixed tight either between the roof and floor or between the sides of a working. The drill is clamped so that it can be adjusted to any position.

Parts of Drills. The various parts of a rock drill are enumerated in the following list. The numbers correspond with those on the sectional illustration of the Holman tappet valve drill shown in 18.

1. Bushing (holder)
2. "U" bolt
3. Pad
4. Cover
5. Buffer washer
6. Piston
7. Cylinder
8. Valve box stud
9. Valve
10. Valve box
11. Valve spring
12. Tappet
13. Rubbing plate
14. Tappet pin
15. Piston rings
16. Piston springs
17. Twist bar
18. End
19. Ratchet
20. Ratchet cover
21. Handle
22. Lock nuts
23. Buffer
24. Washer (ratchet end)
25. Feed screw
26. Twist nut
27. Feed screw nut
28. Cradle
29. Packing
30. Liner screw
31. Side bolt
32. Pawl spring
33. Pawl
34. Liner

Weight of Drills. The pneumatic hammer drill is as light as 16 lb., with cutter. The ordinary mining drill weighs 190 lb., a hand mining drill 240 lb., while heavy quarry drills may go up to 560 lb.; and there are many intermediate weights



22. SINGLE-HANDED DRILLING
(By permission of H. W. Hughes)

Blasting Materials. The substances used to cause the explosion consist of mixtures or compounds which contain combustible material intimately associated with material containing oxygen that will cause it to burn completely; the result is that, when such a combination is ignited, the whole mass is instantly consumed and mostly turned into a gaseous condition which would occupy many hundred times the space occupied by the solid were it not confined in the bore hole. It is the resistance offered to this expansion which creates an enormous pressure on the rocky sides of the bore hole, and results in their disruption. There are a great number of explosives used in mining, but for the preliminary work we are now considering those used would come under the following categories: *Powders* containing the combustibles sulphur and charcoal, with saltpetre as the oxygen supplier; explosives containing *gun-cotton* (this is a solid compound containing the combustibles carbon and hydrogen, along with nitrogen, and sufficient oxygen for their complete gasification); or explosives containing *nitro-glycerine*, which, like gun-cotton, is a compound containing nitrogen, carbon, hydrogen, and oxygen in such proportions that when disturbed by fire or shock they are instantly turned to gases with evolution of heat.

The powders are the least violent of these explosives, nitro-glycerine the most. *Blasting glycerine* is a mixture of gun-cotton and nitro-glycerine, and *carbonite* consists of nitro-glycerine, wood-meal, and saltpetre [see Explosives]. Where ventilation is bad, the products of the explosion must be taken into consideration in making the selection; while where inflammable gas is met with, as in the case of coal, either safety explosives should be used or the hole should be tamped with water to prevent the emission of flames that might ignite the inflammable gas.

For A Short Dictionary of Mining Terms see next page

A SHORT DICTIONARY OF TERMS USED IN MINING

See also Dictionaries of Geology (page 2257), Civil Engineering (page 1961), and Building (page 810)

ADIT—A gallery driven from the open-air into a mine; more particularly the gallery that drains a mine.

After-damp—The atmosphere produced by an explosion of gas in a mine. It consists of carbonic acid, nitrogen, and steam, with a small amount of the highly poisonous carbonic oxide.

Air-box—Wooden tubes for conveying fresh air to workings.

Air-courses—Passages for ventilation.

Air-crossings—Bridged passages for carrying one air-course across another.

Air-doors—Doors for regulating air-currents.

Air-pipes—Pipes for conveying fresh air to workings.

Alloy—A combination of two or more metals.

Alluvial Deposits—Deposits consisting of matter transported by water from higher ground.

Amalgam—An alloy containing mercury.

Amalgamation—The process of the formation of an amalgam; more particularly the use of mercury in the extraction of gold.

Amorphous—Without crystalline form.

Anemometers—Instruments for measuring velocity of air-currents.

Anhydrous—Free from water.

Arenaceous—Containing sand, or sandy.

Argentiferous—Containing silver.

Argillaceous—Containing clay, or clayey.

Assaying—Determining the amount of one or more specified constituents in mining produce.

Attle—Waste rock.

Auriferous—Containing gold.

BACKING DEALS—Planks placed vertically behind the curbs in a shaft to hold back loose fragments

Backs—The unworked portion of a vein above a level.

Bank—The surface land surrounding the mouth of a shaft.

Banket—Auriferous conglomerate consisting of quartz pebbles in a siliceous matrix.

Banksman—The man who receives the tubs at the top of the shaft.

Bar—See *crowntree*.

Basset Edge—Outcrop.

Battea—A very shallow slightly conical dish used for washing gold-dirt.

Bed—A stratified deposit [see *seam*].

Bed-rock—The rock upon which an alluvial deposit rests.

Bind—Shaley layers interstratified with coal-seams.

Bit—The chisel tip of a drill or the drill itself.

Black-band—An earthy carbonate of iron containing bituminous matter.

Black-damp—Carbonic acid gas, CO_2: *choke-damp*.

Blackjack—Zinc blende.

Black Tin—Dressed tin ore.

Blasting—Breaking away rock by means of an explosive.

Blende—Zinc sulphide.

Blower—A sudden emission of fire-damp in a mine.

Blue John—Fluor spar.

Bonanza—An exceptionally rich and persistent body of ore.

Bonnet—Covering to a cage to protect men from falling stones, etc.

Bord—A road driven in a seam at right angles to the main cleavage planes.

Bord and Pillar—See *pillar and stall*.

Bordways Course—The direction at right angles to the main cleavage planes. Also *on face*.

Bort—Opaque dark diamond.

Brattice—A temporary partition for purposes of ventilation.

Bucking—Crushing ore with the bucking iron.

Bucking Iron—A flat piece of iron with a wooden handle, used for crushing samples of ore.

Bunch—A small body of rich ore.

Bunchy Veins—Veins in which bunches occur.

Buntons—Timbers placed horizontally across a shaft.

Burrow—A heap; dump, or spoil heap.

CAGES—The conveyances consisting of platforms with framework used for transporting men, mineral, and material up and down a shaft.

Cap—A piece of wood placed on a prop in timbering. Also called *lid*. In metal mining, *bars* are called *caps*.

Caunter Vein—A mineralised cross-course.

Chimney—A continuous body of ore of moderate width but prolonged in depth.

Chocks—Stacks of pieces of timber laid horizontally with the alternate layers at right angles; also *cribs* or *cogs*.

Choke-damp—Carbonic acid gas, CO_2; black-damp.

Cleat—The more prominent cleavage in a coal-seam.

Cleavage—Planes of weakness in minerals and rocks along which they break up with comparative facility.

Cobbing—Removing adhering ore from pieces of veinrock with a hammer.

Cogs—*Chocks*.

Contact Vein—A vein lying between rocks of different character.

Corves—The small waggons or cars used for the conveyance of minerals, etc., in mines; also called *trams* or *tubs*.

Costeaning—Seeking deposits by sinking shallow pits and connecting them by an underground gallery.

Country—The rock or rocks in which a vein occurs; also called country rock.

Course—See *strike*.

Cradle—A wooden box with sieve mounted on rockers, used to wash gold-dirt.

Creep—The forcing up of the floor by the pressure of surrounding beds in mine roads and workings.

Crib—Framing timbers in a shaft; also a *curb* or a *chock*.

Cropping out—The appearance of a vein or bed at the surface.

Cross-course—A barren vein having a different direction to the main veins of a district; similar to a fault.

Cross-cut—A gallery driven in the country.

Crowntree—A piece of timber set on props to support the roof; sometimes called *bar* or *cap*.

Curbs—Frames employed as foundations for walling or tubbing in a shaft.

DEAD GROUND—Parts of veins without ore or deficient in ore.

Deadwork—Unproductive work.

Deads—Waste rock; *attle*.

Development—Operations conducted to render the useful minerals in deposits accessible.

Dial—A pattern of compass used underground.

Dialling—Surveying a mine by means of a dial.

Die—See *stamps*.

Dip—The deviation of the slope of a bed or vein from the horizontal.

Dipping Needle—A magnetised needle swinging in a vertical plain.

Downcast—The shaft through which the downward current of air passes into a mine.

Downthrow—The downward displacement of a seam by a fault.

Dressing—Separating ores from accompanying rock and minerals.

Drift—Any passage underground that is horizontal or nearly so.

Driving—Excavating drifts.

Dropper—A small branch vein on the footwall side.

Dumb-fault—A *wash-out*.

Dump—A waste heap; spoil heap.

Dyke—A vein of igneous rock.

EXPLOITATION—The productive work in a mine.

FACE—The exposed surface of mineral in a working.

Fault—The dislocation of a vein or seam. [See Geology.]

Feeder—A small branch vein.

Fiery—Containing explosive gas in dangerous proportions.

Fire-damp—Methane or marsh gas, CH_4.

Float Gold—Very finely divided or flaky gold, which floats on water.

Flookan or Flucan—A cross vein filled with clayey matter.

Floor—The stratum immediately below a seam or bed.

Flume—An artificial water-course.

Foot-wall—The under-wall of a vein.

Frame—An inclined wooden slab used in dressing-tin ore.

GAD—A pointed wedge.

Gallery—A drift.

Gangue—The worthless portion of the contents of a vein; called also *veinstuff*, *veinrock*, or *matrix*.

Gate—A road kept open in the worked-out part of a mine; called also *gate-road*, or *gateway*.

Gin—A primitive form of winding engine; a whim.

Goaf—The worked-out ground of a coal-mine.

Gob—Same as *goaf*.

Gold-dirt—Earthy material containing particles of gold.

Gold-washing—Separating the particles of gold from the dirt by washing with water.

Gossan—The cellular and deeply stained material found at the top of some veins.

Grass—The surface of a metal mine.

Grizzley—A grating.

HADE—The deviation of the slope of a vein or seam from the vertical.

Hanger-on—The man who runs the loaded tubs on to the cage.

Hanging-wall—The upper wall of a vein.

Head Race—Aqueduct for the supply of fresh water.

Heads—The enriched products of ore-dressing. Also see *stamps*.

Headways Course—A direction parallel to the main cleavage planes.

Heave—The lateral displacement of a vein by a fault.

Hewer—The miner who *holes* the coal.

Hitch—A small fault.

Holing—Making the horizontal cut in a seam, usually below it, or in the lower part of it, called *undercutting*.

Horse—A mass of country in a vein.

Hushing—Flushing the surface away with water to expose a hidden deposit.

Hydraulicing—Washing away a deposit into special channels called sluices by powerful jets of water.

INBYE—Going from the shaft (underground).

Intake—The road along which the fresh air passes in a mine.

JENKIN—A road cut bordways course in a pillar of coal.

Joints—Natural divisions in masses of rock.

Jud—A working place driven in a pillar of coal.

Jigging—A process of ore-dressing and coal-washing in which sifting and water buoyancy act together.

Jumper—A weighted iron or steel bar with chisel end used for drilling holes in rocks by hand.

KIBBLE—A mining bucket.

Kindly—Applied to veinstuff and country; tender, soft, easy, promising-looking rock.

Kirving—Synonymous with *holing*.

LAGGING—Small timber driven behind the main timbering in shafts or drifts to prevent loose fragments falling through.

Launder—Water trough, also a *flume*.

Leader—A branch vein.

Leg—The upright timbers supporting the *cap* in vein-mining timbering.

Levels—Drifts driven along a vein.

Lid—See *cap*.

Lift—Any working place a few yards wide driven in a pillar of coal.

Lode—The profitable portion of a vein, frequently the vein itself.

Long Tom—A wooden sluice used in gold-washing.

Longwall—A method of working by which the mineral is removed in one continuous series of operations.

MAN-ENGINE—An appliance used for raising and lowering men in shafts.

Matrix—The material in which a useful mineral is embedded.

Metalliferous—Containing a metal or metals of the heavier type.

Middles—The intermediate products in ore-dressing operations.

Mineralised—Containing metalliferous minerals.

Mortar—See *stamp*.

NICKING—Making a vertical cut or groove in a face of coal.

Nip or Nip out—A sudden thinning of a seam or vein.

ON END—Headways course.

On Face—Bordways course.

Open-cast—Workings in the open air.

Ore—Mineral worked for the metal it contains.

Ore-dressing—See *dressing*.

Out-bye—Towards the shaft (underground).

Outcrop—The part of a deposit exposed at the surface.

Overburden—The surface material covering a deposit of useful mineral.

Overhand Stoping—A system of extracting ore from a vein by excavations made overhead.

PACK, OR PACK WALLS—Pillars of rough waste stone built to support the roof in mining.

Pan—A shallow dish used in washing gold.

Panels or Districts—Areas of a coal-seam isolated by means of barriers of untouched coal, to ensure more agreeable and safer conditions of working.

Panning—The operation of washing gold in a pan.

Parting—An inter-stratified layer of foreign material in a coal-seam.

Pass—A passage kept open for transmitting ore or rock to a level below.

Pay-dirt—The valuable portion of alluvial deposits.

Piling—Sinking shafts through loose ground by driving piles down, behind cribs or curbs.

Pillar—A block of mineral left to support the workings.

Pillar and Stall—A system of working in which the deposit is in the first working cut into blocks or pillars, which are subsequently removed in the second working; also known as *post and stall, bord and pillar, stoop and room.*

Pinch—A vein is said to pinch when it gets gradually thinner, and if it then disappears it is said to *pinch out*.

Pipe—Similar to a chimney, also the penetration of an upper bed into a lower one.

Pit—A shaft, also an open working in soft material.

Pitwork—The pumps and other appliances in the shaft.

Placer—An auriferous alluvial deposit.

Plat—An enlargement in a shaft.

Pocket—See *bunch*.

Pockety—See *bunchy*.

Post and Stall—See *pillar and stall*.

Pulp—In ore dressing, the product of the fine crushing of ore in the presence of water.

Punch-prop—A strut or distance-piece placed between the cribs in the temporary timbering of a shaft.

Putter—Trammer.

Pyritous—Containing pyrites.

QUARTZOSE—Consisting chiefly of quartz.

RAGGING—A heavier stage of spalling.

Raise, or Rise—A passage driven upwards in a mine.

Reef—A vein.

Riffles—Obstructions placed in the bottom of sluices, etc., to facilitate the deposition of gold, generally strips of wood.

Roof—The stratum immediately above a seam or bed.

SAFETY LAMP—A lamp in which dangerous contact between the external atmosphere and the flame is prevented by the use of wire gauze.

Sands—In ore dressing, the heavier products of hydraulic separators.

Seam—A tabular or sheet-like deposit forming one of a group of stratified rocks used in a more restricted sense than the term *bed*.

Set—A complete unit of framing in shaft or level timbering.

Shaft—A deep pit sunk from the surface.

Shaft Pillar—A block of mineral left to support a shaft.

Shoading or Shoding—Tracing detached stones to the parent vein.

Shoe—See *stamp*.

Shoot—A continuous body of ore extending downwards; also a *pass*, or the lower end of a pass.

Sill—The bottom member or sole-piece of a set of timber in a level or drift.

Skip—A rectangular box, working in guides in the shaft, used for winding ore or rock, etc.

Skirting—A road driven alongside fallen stone.

Slide—A small fault or dislocation.

Slimes—In ore dressing, the lighter products of hydraulic separators.

Sludger—A cylinder with a valve at the bottom for removing crushed stuff from a bore hole.

Sluices—The large wooden troughs used as a channel for the stream of water and dirt in hydraulic mining.

Sole-piece—See *sill*.

Sollar—A platform in a shaft.

Spalling—Breaking down lumps of rock or ore with heavy hammers.

Spitzkasten — Inverted pyramidal boxes used in ore-dressing.

Spitzlutten—Double V-shaped troughs used in ore-dressing.

Sprags—Short props of timber.

Stamp—A weight used in comminuting ore, consisting of a *head* in which is fixed a replaceable *shoe* below and a *stem* above; the stem carries a *tappet* which is periodically engaged and released by a revolving *cam*, causing the stamp to rise and fall. The stamp works on a *die* in a narrow box called a *mortar*.

Stamping—The process of reduction by means of stamps.

Stanniferous—Containing tin.

Staple—An underground shaft or *winze*; also a small pit.

Stemming—Tamping.

Stockwork—A deposit consisting of a number of small veins or patches of ore near together.

Stoop and Room—See *pillar and stall*.

Stope—The place where the mineral is won in a vein mine.

Stopping—A wall built to stop the passage of air.

Stowing—Filling a place with waste.

Stratum—A bed or seam.

Strike—The direction a vein or bed takes across country.

Stringers or Strings—Thin branch veins.

Stringing Deals—Planks employed to hang curbs together in the temporary lining of a shaft.

Studdles—Timber struts or distance pieces used to keep the *sets* apart in shafts in vein mining.

Stulls—Timbers or platforms fixed in stopes for supporting waste rock.

Stythe—Carbonic acid gas.

Sump—The lowest part of the shaft; a drainage pit.

TAILINGS—The impoverished and discarded products of ore-dressing operations.

Tail Race—Channel for conveying away dirty water and tailings.

Tamping—The material used and the operation of filling up a bore hole in front of the charge of explosive.

Tappet—See *stamp*.

Thill—The floor of a mine.

Throw—The vertical displacement of a seam by a fault.

Timbering—Fixing timbers to keep excavations free from obstruction by falls of stone.

Tinstone—Ordinary tin ore.

Trammer—A man who does the tramming of mineral and works the tubs.

Trend—Strike.

Tributers—Miners who work for a percentage of the profits.

Trommel—A revolving screen.

Tubbing—A continuous water-tight lining of a shaft.

Tut work—Contract piece work.

UNDERCUTTING—Holing beneath or at the bottom of a seam.

Underhand Stoping—Working out a vein downwards; the reverse to overhand stoping.

Underlie—Synonymous with *hade*.

Unstratified Rocks—Rocks not occurring in regular beds or strata.

Upcast—The shaft for conveying the vitiated air out of a mine.

Upthrow—The upward displacement of a seam by a fault.

VANNING—Separating ore from veinstuff by washing on a shovel.

Veinstone—The worthless material in a vein.

Veinstuff—Same as *veinstone, gangue,* or *matrix*.

WALLS—The sides of a vein.

Wash-out—A portion of a seam that has been denuded, also called a *dumb fault*.

Whim—See *gin*.

Whip—A winding pulley.

Whits—Partly dressed tin ore.

Winding Engine—An engine used for drawing mineral, etc., up a shaft.

Winze—A shaft extending from level to level.

Working in the Broken—Removing or *robbing* the pillars in the pillar and stall method.

Working in the Whole—Forming pillars by roads driven at right angles to each other, in the pillar and stall method of working.

continued from page 2477

HOW TO WASH CLOTHES

Preparations for Washing. Removal of Stains. Disinfecting Garments. Sorting the Articles. Flannels, Coloured Garments, etc.

By ALICE E. MARSHALL

IN order that the work of washing may be made as little troublesome as possible, it should be carried out systematically.

One day a week should be sufficient to set apart for washing, and this should be adhered to whenever possible. Monday or Tuesday may be chosen as most convenient, but it is undesirable that a later day should be selected.

Before washing day, the methodical housewife will look over her soiled linen, and attend to any mending that is required.

Removal of Stains. Stains, such as those of tea, coffee, and ink, should be removed before washing. Sometimes it is impossible to get rid of these by washing, and if the linen is allowed to go into the boiler with the marks still on, a permanent dye will result, as boiling fixes the colour. Stains may be removed from linen in various ways, different stains yielding to different treatment, as follows:

FRESH INK. Soak the stained part at once in milk or butter-milk.

IRONMOULD. Place the stained part over a basin, sprinkle with salts of lemon, and pour boiling water through it.

TEA OR COFFEE. Pour boiling water through the part stained at once; if this has no effect, sprinkle it with powdered borax.

WINE OR FRUIT. Sprinkle it with salt, and pour boiling water through it; add borax if necessary.

PAINT. This can be removed from white material with paraffin. For coloured materials, rub turpentine or paraffin on the spot.

GREASE. In the case of grease on coloured materials, rub the part affected with rectified benzine; as this is highly inflammable it should be very carefully used.

MILDEW is most difficult to remove. Wet the spots, rub them with soap, sprinkle them with chalk, and bleach in the sun. Repeat if necessary. Chloride of lime is effective in some cases, but needs to be used cautiously, as it may possibly destroy the fabric. After treatment the articles should be washed at once in the ordinary way.

Disinfecting. In cases of illness the clothes need disinfecting before being washed, and should be kept apart from the other linen. However slight the illness may be these precautions should not be neglected, as they may save a great deal of trouble and anxiety.

In serious illness of an infectious nature, the sanitary authorities take the responsibility, and do the disinfecting far better and more completely than is possible by a private person. The point aimed at in disinfecting is, of course, to destroy the germs which spread and carry disease, and which are frequently conveyed by clothing. The surest way of destroying them is by the application of great heat, but this is impossible in ordinary households without injury to the fabric, special appliances being necessary for the purpose. The usual method is to use some disinfectant, such as carbolic acid or Sanitas, which will destroy the power of the germs without injuring the colour or texture of the material. The disinfectant is added to the steeping water in which the clothes are placed directly after they have been removed from the patient. Two tablespoonfuls of carbolic acid may be added to one gallon of water, or the same amount of Sanitas may be used. It is well, in cases of influenza, to add the latter to the water in which the handkerchiefs are steeped, but it is not so powerful in its effects as the carbolic acid. Care must be taken in using the acid, owing to its being a deadly poison.

Chloride of lime and permanganate of potash are good disinfectants, but if used in sufficient strength to be of service, they may injure the colour and fabric of the articles disinfected.

Sorting the Clothes. When preparing for washing day, all soiled clothes must be collected and sorted into heaps, the flannels and prints being rolled up and placed on one side, as these need special treatment.

The usual method of sorting is to separate the articles in this way:

Table linen
Bed and body linen
Starched articles:
  collars, cuffs, etc.
Handkerchiefs
Muslin, laces, etc.
Coarse articles

These are put in different tubs, being well covered with cold water for at least twelve hours. This preparatory steeping greatly reduces the actual labour of washing, as it softens and loosens the dirt, making it much easier to remove from the clothes. If necessary, the starched articles may be put with the body linen, but the handkerchiefs must always be kept separate from other clothes. One tablespoonful of salt should be added to the steeping water, as this assists in the cleansing.

Preparations for Washing. On washing day, the worker should rise early, fill the copper, and light the boiler fire. The flannels and prints may be washed and put to dry out of the way. The latter are sometimes boiled, but this is not usual, as boiling affects the colours. Starch may be made ready, both hot and cold. The latter is generally used when great stiffness is required, as for collars and cuffs. Boiled starch is used for table linen, muslins, etc.

How to Make Starch. The best starch for laundry purposes is rice starch; the other kinds have much coarser granules, and are not suited for fine work. It will not properly dissolve in cold water, but only when boiling water is added; the cells burst, and a thick paste is formed. The best starch costs fourpence per pound.

BOILED STARCH

1 tablespoonful of white starch
2 tablespoonfuls of cold water
½ in. of wax or tallow candle
¼ teaspoonful of borax

Mix the starch to a smooth paste with the cold water; shred in the wax or tallow candle (composition candles must not be used); dissolve the borax in a small quantity of boiling water, and add it to the starch. Pour on sufficient boiling water to cook the starch, stirring all the time until quite clear and transparent; add cold water gradually, and use according to the desired stiffness.

Muslins and curtains require a stiffer starch than table linen; the finer and more open the fabric, the less starch it retains.

Borax is added to the starch to give a gloss to the linen, and tallow or wax to make the iron slip along easily without sticking.

COLD STARCH

1 tablespoonful of starch
4 drops of turpentine
½ teaspoonful of borax
¼ pint of cold water

Mix the starch to a smooth paste with a little of the cold water and drop in the turpentine. If this is added at the last it swims on the top of the water and does not mix easily with the starch. Add the borax, previously dissolved in a little boiling water, then the remainder of the cold water.

Stir the whole well each time before use, as the starch sinks to the bottom of the basin. If the starch is good it will settle in a solid cake. In impure starch there is a sediment which will not dissolve; this sticks to the irons, and the work is ruined as far as appearance goes. After all the collars, etc., are done, the starch may be allowed to settle at the bottom of the basin; the water is then poured off, and the starch is used up for boiled starch. It should be kept covered until required. It is unsuitable to use again for cold starch, as the exact proportions cannot be ascertained, and as this is one of the most important items to note in the successful getting up of linen, it is not wise to attempt it.

Cold starch is always better if made a short time before it is required; the standing softens the starch grains and they burst and swell when the heat of the iron is applied, entering into the material and giving it the requisite stiffness.

The Washing of Flannels. Flannel articles should be sorted according to their nature and colour, the white ones being taken first, then the Jaeger and "natural," and the coloured last. The point to aim at in the washing of woollen and flannel garments is the retention of their soft nature without any shrinking or discoloration. The following points should be noted:

Do not leave woollen garments lying about wet; it causes them to shrink.

Avoid rubbing soap on them; the soda in the soap has a bad effect, causing them to harden, and also turning white wool yellow.

Avoid extremes of heat and cold; warm water is the best.

Do not dry the clothes in the sun or directly in front of the fire; they should not be allowed to "steam."

White Flannels. White flannels should be treated in this way:

1. Shake them to remove the dust.
2. Prepare warm water (one part boiling water to 1½ parts cold water is the right heat for washing and rinsing flannels).
3. Add sufficient melted soap to make a lather, and a few drops of ammonia to soften the water and remove grease.
4. Squeeze the articles gently in the water between the hands, but do not rub them; turn them and repeat the process until they are perfectly clean.
5. Rinse them in water of the same heat until all soap is removed.
6. Fold and pass them through a wringer two or three times.
7. Shake them well to raise the nap.
8. Dry them in the open air, if possible, hanging them up by the thickest part.

Woollen Articles. Jaeger and natural wool is washed in the same way as white, except that the garments may be steeped in the prepared water (that is, warm water, ammonia, and melted soap) about twenty minutes, the bowl being closely covered to prevent the escape of the ammonia. They will then be found to be practically clean, only requiring to be squeezed out and rinsed in clean water before wringing and drying.

Coloured Garments. Coloured garments may be washed like white ones, with the exception of the ammonia, which should be omitted, as it affects certain colours. The water should also be a little cooler, and the articles should be washed and dried quickly to prevent the colour from running. Salt is added to the rinsing water, as it assists in retaining the colour. One tablespoonful of vinegar may be used to brighten the colours, particularly red, blue or pink.

Stockings. Stockings are the only woollen articles to which soap is directly applied, and a little may be rubbed on the feet to get them perfectly clean; they must be turned and rubbed both sides until quite clean and soft. Stockings should not be washed in the water which has been used for white flannels, as the fluffy pieces come off the flannel and spoil the appearance of the stockings or socks. They should be folded down by the back seam in the natural shape, the foot being turned on to the leg part. Then pass them through the mangle two or three times to remove as much water as possible; hang them out in the open air to dry, pegging them up by the toes.

'TWIXT SPINDLE AND LOOM

Reeling, Winding, and Spooling Cotton, Wool, Flax, Hemp, and Jute. Winding, Throwing, and Cleaning Silk

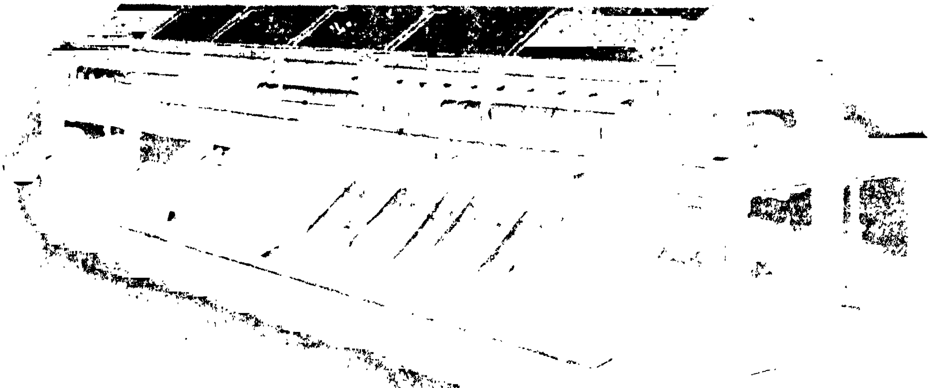
By W. S. MURPHY

Reeling. Spun yarn was always reeled into hanks in the days before mechanical invention had made the manufacturing process continuous. That is the reason why the measurements of yarns are based on the hank. When we speak of 40's yarn, we mean that so many hanks of a given length will weigh a pound. At present the young worker may be confused by the fact that none of the yarn he handles is made up into hanks at all. For example, many warp yarns are taken directly from the ring spinner on bobbins and put on the warping mill; still more commonly, the weft bobbins are wound on to the cops for the loom by the winders.

Most factories have a way of dodging the reeler, so that we have not nearly so many reelers as formerly. Reeling is not a difficult operation; the machine is the very simplest we use. The reel is a long cylindrical frame [98] hung on a spindle at the back of a machine on the front of which are set the cops or bobbins to be reeled. Through finger-like guides the yarn is led up and round the cylinder. The cylinder revolves till the standard quantity of whatever yarn we use has been wound on, and then it automatically stops. The indicator is generally of the worm-wheel type, every revolution of the reel giving it a turn, till it comes forward to the wheel or wire controlling the drive, and gives it the nudge.

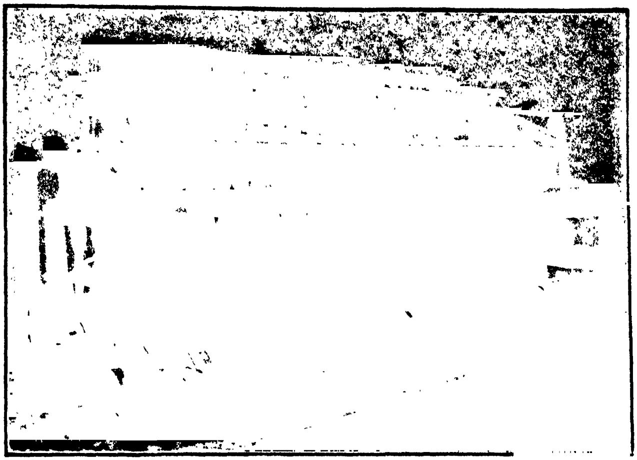
Though not important in itself, the reeling operation is interesting as the basis of yarn measurements. We have complained about the lack of a proper standard of measurement, but the trouble really arose, in the first instance, from the different sizes of reels used. The standard was a revolution of the reel. A common worsted reel was 36 in.; the cotton reel measured 54 in.; the linen reel was 90 in. in circumference. With a unit so diverse, the multiples were bound to give different results. Linen manufacturers took 120 revolutions of the reel as the next unit; worsted men decided upon 80 revolutions; the cotton workers agreed to make 80 revolutions of the reel the standard also, but their reel was half a yard longer than the worsted one, and so the difference was perpetuated. With the comparative disappearance of the reel, we may hope that some universal standard will be possible at an early date.

Winding. Winding is the opposite of reeling, with a difference, and that difference still keeps winding an integral part of the textile industry. First, we require spools or *cops* for weaving. These may be formed from hanks or bobbins; but the winding must be done. Secondly, there is the silk winding, the yarn of which has been left on the hank, so far as we are concerned. Thirdly, there is the spool winding for all classes and kinds of threads. We arrive here at one of those points where the different branches of the textile industry have taken different departures at various moments. Some combine winding with doubling; others wind from hanks for weft; and others, again, wind the spools for the weaver from bobbins. These, and many other differences, may be viewed properly if we take the simplest first, and then develop as we go along.



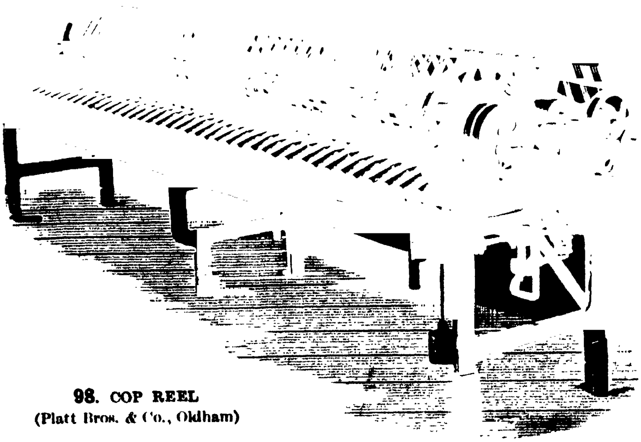
96. WINDING MACHINE
(Whiteley & Sons, Lockwood)

Cotton Winding. On the older form of winding-frame the hank to be wound is stretched on the reel at the back, and the cops or bobbins to be filled placed in front. But that order is reversed on the newer frames. At a slant, the hank is stretched in front of the frame [96] on two sparred drums, and the yarn is drawn off and wound on bobbins at the head of the frame. The most noteworthy parts of those simple machines are the guides and stop-motion contrivances.



97. DOUBLING FRAME (John Sykes & Sons, Huddersfield)

The form of the guide varies with the general character of the machine and the purpose to which it is devoted. In every case, however, it acts like a finger, holding the thread and carrying it to and fro along the bobbin, laying on each round with accurate regularity. In some machines the guide and the stop-motion apparatus are connected. For example, the end of the hooked wire connects the spindle with the drive; when held in position by the thread the wire maintains the drive; when the thread breaks or runs out, the wire falls and the spindle stops. In many ways this principle is worked in many machines, and the reasons for its use are very good. We must have the same length of thread on every bobbin, and the length is measured by the number of turns which the spindle makes. If the spindle were to run on after the thread had broken, our measure would be lost. As it is, all we have to do is to join the threads, hook up, and let the spindle begin again. The measure of the thread will be exact.



98. COP REEL
(Platt Bros. & Co., Oldham)

99. FANCY TWISTING FRAME (John Sykes & Sons, Huddersfield)

The winding machines of the various yarns differ in size and in minor details, but no variation in principle is possible. One cop-winding method, however, should be noted, because it has affected the form of weaving shuttles in many branches of the trades. A hollow cone is geared over the bare spindle of the winding machine, and as the thread passes through the cone, by an oscillating motion, builds up the cop.

demand a good sound thread, rapidly produced. As a rule, if intricate in mechanism, they may be safely disregarded, and if simple, they will be easily understood.

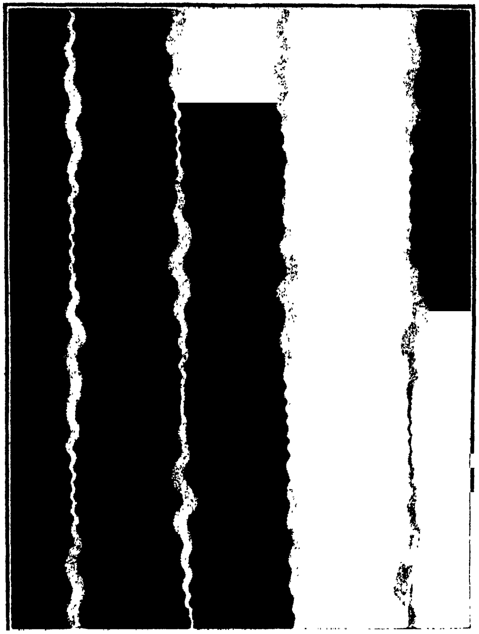
Conditioning Flax and Hemp. After it has been spun, the wet flax is dried in heated stoves, generally apartments over the boilers of the factory. Hung upon poles, within the heated room, through which a current of air is constantly driven by an arrangement of fans, the yarns are speedily dried. Next, the flax is made up in bundles, if for outside use or for sale on the market as yarns. Let us suppose, however, that we weave as well as spin. From the drying-room the yarns are taken and carefully boiled and washed. These are simple operations; but it is necessary to state that they must be done. When brought from the washing department, a considerable change is observable on the flax yarns. Not only are they cleaner, but they are also lighter and more flexible.

The boiling and washing process has seemed to many manufacturers unnecessarily severe on the linen yarn. Hemp yarns also need softening. These two facts in conjunction have led to the invention of dry softeners, designed primarily to soften hemp, but capable of being used for flax also. As a rule, the softeners are easily worked. The object being to give pliability to the yarns without alteration of their character, the softener must be used carefully. A very good type is the four-hank machine [103] made by Jennings, of Leeds. On each side are two pairs of flanged pulleys and a pair of drums, working on each other, with simple guides. The pressure of the softening drums is regulated by hanging weights, which are readily adjustable. The hanks are hung on the pulleys, and led through the guides in between the softening drums. The effect is undoubtedly to render the yarn more pliable and give it better spreading quality in the weaving.

Silk Spinning and Throwing. Spinning, in the strictest sense of the term, is not applied to silk; the silkworm has spun the thread for us, and we have to put it to use in producing textiles. Only when they have come off the spinning machines can the other fibres be said to be on a level with silk. This wonderful fibre in its raw state, however, has defects of its own, and the processes we name *spinning* and *throwing* are designed to remove these. Waste silk is spun like cotton or wool; but it must always be regarded as a subsidiary branch of the silk industry.

Sorting. In a former lesson we studied silk culture, and noted the various stages of the silkworm's life from the egg to the cocoon. We inquired into the structure of the cocoon and the various methods of reeling practised. When the raw silk arrives at the factory in this country it is made up in the hanks formed by the reelers of the cocoons. These hanks are first taken to the sorters, who open and lay them out for separation into the various qualities. Sorters have two methods of judging—one is by skilled sight and touch, and the other is by length to weight. We sort the silks into lots, according to the degree in which they possess these qualities: 1, fineness; 2, regularity; 3, clearness; 4, freedom from knibs or knots. Mechanical aids are useless here; sorting is a craft which can be acquired only by experience. Weighing, on the other hand, is purely mechanical.

Winding. While we have many very fine modern winding machines adapted from the other textile industries, the simple and primitive silk-winder is still in use in many factories. The reel is composed of slips of lancewood joined in a hub on the supporting rod; on the head of the frame the bobbins sit on spindles between small pulleys actuated by the friction of a driving roller; in front are the guide wires fixed on a traverse rail moved to and fro by the cams at the sides. The hanks are hung on the reels, which, by their structure, are capable of taking on any size of hank, the stretch being made firm by bands of twine. Reels so large and light would very readily develop high speed and overrun; but a weight is attached to each, steadying the unwinding movement. A difficulty in all these winding machines is to obtain the smooth and regular delivery of the thread or yarn, friction being almost unavoidable. One of the best devices for getting rid of that trouble is the winding machine [104], which stretches the hanks on a pair of swifts slanted up towards the bobbins, and drives both bobbins and hanks by the same gearing. This equalises winding and delivery, and the lie of the hanks obviates all friction.



102. SPIRAL YARNS

Cleaning. The cleaning, or re-drawing frame is also a simple structure, but the work calls for watchfulness and skill. Like every other, this department is always getting more

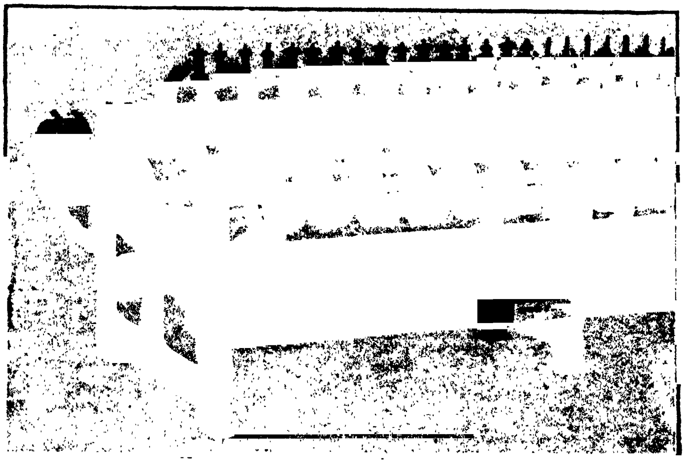
103. YARN SOFTENER (Thos. Jennings & Sons, Leeds)

except the cleaners. Each cleaner is a pair of steel blades, set vertically in an adjusting screw, the edges of the blades facing, and in close proximity. The silk passes through the blades, which are adjusted exactly to the normal diameter of the thread, and cut away all knibs or irregularities. But another function of the cleaners here comes into view. The frame is so finely set that if the silk is too thick, it stops; if too thin, it tends to overrun. Therefore, the sizes of the spaces between the cleaner blades are delicately graded, the thick to the one hand, and the thin to the other. When a thread is stopped, it should be removed to the proper grade, and the same in the case of a thin one. So, by this arrangement, we obtain two classes of threads. Of course, the operation of cleaning may be repeated as often as may be considered necessary.

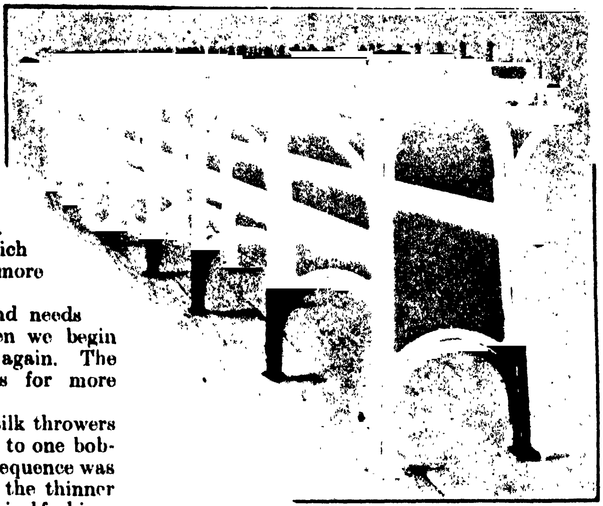
Doubling and Spinning. When the silk comes from the cleaners, three courses are open. We may use the silk as it stands for warp and weft of fine gauzes and light silk cloths. In that case the bobbins are sent straight to the warpers and pirn winders. Though dull and

104. SILK WINDING FRAME (Whiteley & Sons, Lockwood)

and more improved machines. The latest is a cleaning-frame of high efficiency [105]. The bobbins are set on the head of the frame, and the thread is passed through sets of cleaners down to the bobbins, the winding of which is regulated by drums. More generally used, however, is the older type of frame. On the front of the frame is a bobbin board, which holds the bobbins on spindles; above it is the guide roller; behind, the cleaners or clearers sit in one long row; at the head, again, the receiving bobbins. Nothing in this machine is worthy of special note



105. SILK CLEANING AND GASSING FRAME (Greenwood & Batley, Ltd., Leeds) lustreless on the web, these cloths are bleached into the most lustrous of all silks, because the natural gloss of the fibre is allowed to appear. Or we may want the silk for what is called *tram*, generally used as weft in heavy silk fabrics. In this case the threads are taken to a doubling-winding frame, and there put together with the lightest twist possible. Or, again, it may be *organzine* which is required, and in this case a more elaborate process is demanded.



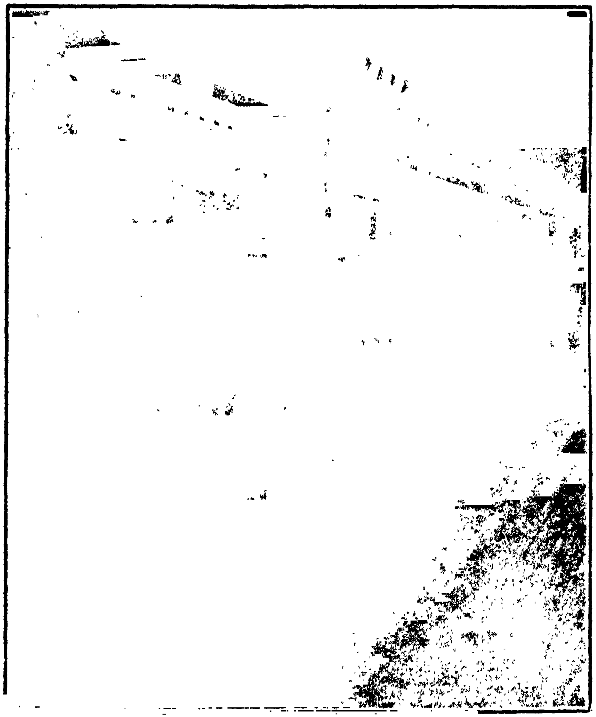
106. WASTE SILK CLEANING FRAME
(Enoch Rushton & Sons, Macclesfield)

The first case explains itself, and needs no further study at present; when we begin weaving, these threads will appear again. The formation of tram, however, calls for more special study.

Tram. Up till a few years ago silk throwers simply ran two threads together on to one bobbin in doubling for tram. The consequence was that in the case of unequal threads the thinner wound itself round the thicker in a spiral fashion, when they were twisted. A more sensible method is to twist and double at the same moment, and this is done on the doubling-twisting frame. On a creel the two bobbins are placed together, and the threads led into a twiner; thence the doubled thread goes on to the flyer, which gives it the necessary twist, and lets the bobbin wind the silk round itself. It is considered that about five turns to the inch is quite enough for tram.

Organzine. The making of organzine involves several operations. First, the single thread has to be twined into what is called "singles." The approved method of performing this work is by the use of a kind of inverted throstle-frame. The bobbin containing the cleaned thread sits on a creel at the bottom of the frame, and on its head is a curious flyer, one leg by the side of the bobbin, and the other twined round a wooden boss on the head of the spindle and turned upright. Above is the traverse rail, with an eyelet, and on the head rests the receiving bobbin. The bobbin holding the cleaned silk is stuck firmly on the spindle, and, of course, the flyer is driven at the same speed. Through the eyes on both legs of the flyer, and up through the eyelet of the traverse rail, the silk passes on to the bobbin, the amount of twist being determined by the difference between the rates of speed of the delivering and the receiving bobbins. If the silk were taken on as quickly as the delivering bobbin turned, there could be no twist.

Having got our *singles*, as the twisted thread is called, we now proceed to doubling and twisting. This may be performed either in one operation, as described in the formation of tram, or we may double first, and then twist. Serious objection to two operations is not taken, because the singles, being twisted, have some body. One thing must be observed—the doubling twist should be contrary to the twist of the singles, so that



107. ORGANZINE-SPINNING FRAME
(Enoch Rushton & Sons, Macclesfield)

the pull of the singles to untwist confirms and hardens the twist of the doubled threads. Silk net-thread is best treated on the double-tiered machine [107], which "spins" a large amount in a short time.

As we have more than hinted, the student of silk-throwing will learn his own trade and a little more by paying close attention to the winding and doubling operations of the other textiles. In machinery this is especially the case.

Reeling. When the silk leaves the doubling frames, either as tram or organzine, it is reeled again into hanks. This time the winding operation is reversed, the reels taking on instead of giving off the hanks. Many forms of reeling machines are made, but the operation, being merely the unwinding of a bobbin on to a reel, is simple. Self-acting count-guiders and stop motions have been attached to all reeling machines, each maker having a special contrivance, or, rather, special adaptation, of the principle common to the whole trade. By the automatic count-guide it is possible to make the hanks of any length desired. Skeins, or hanks, had no common measure till very recently. The unit most generally accepted is 1,000 yd., skeins of 500 yd. and 250 yd. being denominated half-skeins and quarter-skeins. Some firms stick to the old French measure of 520 yd. Similarly, the standards of weight differ. The English unit of 1,000 yd. is weighed in avoirdupois drams, the silk being named according to the number of drams the skein weighs. With skeins of the French length, the weight is expressed in an old measure called *denier*, of which we find 20 equal 16½ gr.

Though the varieties of silk yarns are very numerous, the methods and machines we have examined represent all the principles involved. The silk-thrower's work is mainly doubling and twisting, and these operations, while calling for considerable care and practical skill, are easily understood and quickly learned.

Spun, or Waste Silk. After the waste silk has been spun into thread, it comes into line with the reeled silk. When spinning it we saw a lot of irregularities, knibs, and knots, and these may be removed by the same cleaning process as has been given to common silk, or by another process called *improving*. We have two different kinds of improvers. One is a frame [106] with little glass eyelets, through which the thread is drawn from one bobbin to another, the glass clearing away the irregularities in the same way as the cleaning blades. The other is rather more ingenious in principle, though not so economical in practice, and therefore not so much used. It is worth studying, however. On a cleaning bar revolving spindles are ranged in the frame, and in its passage from bobbin to bobbin the thread winds itself round these and rubs, the friction effectually wasting away the lumps and knots. Improving lessens the bulk of the thread more than might be desired, but the improvement is certainly very remarkable.

Gassing. The improving operation takes away the knibs, or knots, but it leaves untouched, and even exaggerates, another defect which would lessen the value of the yarn very considerably if it could not be got rid of. When taken off the improving machine, the silk appears dull and lustreless. Examining it attentively, we see that the thread is covered with a soft down, which, under the microscope, seems a hairy coating. Those slender filaments intervene between the straight fibres of the body of the thread and the light, and so hide their lustre. Fortunately, some time before waste silk spinning had become a very important branch of the textile industry, the gassing frame had been invented.

In 1817, Samuel Hall, of Nottingham, invented a gassing apparatus, primarily designed to remove the floss from the threads of lace, but applicable to all classes and kinds of threads and fabrics. The gassing machine commonly used by the spinner of waste silk closely resembles the improver, with the difference that, instead of the glass eyelets or upright steel blades a row of gas-jets are placed in the way of the passing threads. These jets have not the white flame of ordinary gas, because they are cooled by air, to moderate the heat for the fine threads of yarn. From bobbin to bobbin, the threads are led through the little blue jets, and are cleared of the floss, which is burned off in the flames, while the body of the yarn remains uninjured.

Various patterns of gassing frames are to be had, and we do not feel disposed to question the efficiency of any. The user of the gassing frames, however, must observe certain points. Some silk yarns are more tender than others, and need to be gassed more rapidly, or in a lower degree of heat, than others. Again, the yarn should not be drawn, or otherwise wrought, on the gassing machine, and therefore delivery and taking-on should be perfectly equal. If desired, the gassing operation may be made part of the winding or spooling. On these frames, the gas-jets are set amid the reach between delivery and winding-on spools, and so consume the floss from the thread as it passes.

Thus cleared of floss, the waste-silk yarn shows a lustre rivalling that of its more costly rival.

Because the yarns of spun silk are more uniform and rounder than those of thrown silk, they are preferred for machine sewing-thread and laces. From being regarded as an inferior intruder, the waste-silk industry has attained an integral position among textiles.

PROPERTIES OF LIGHT

Reflection of Light and its Laws. A Study of Reflected Images. The Real Eyes are in the Back of the Head. The Kaleidoscope

Group 24

PHYSICS

18

Continued from page 2498

By Dr. C. W. SALEEBY

The Facts of Reflection. Having defined the terms *transparent*, *translucent*, and *opaque*, and having noted the fact that light may be absorbed by a material body, we must now inquire into the laws which determine reflection of light from those bodies which, exactly in so far as they do reflect it, are opaque.

"When a ray of light," says Professor Tait, "moving in one homogeneous medium falls upon the bounding surface of another homogeneous medium it is, in general, divided into several parts, which pursue different courses. These parts are respectively (a) *reflected*, (b) *refracted* (singly or doubly), (c) *scattered*, (d) *absorbed*."

In certain cases the whole of the light is reflected, and this we call *total reflection*. In general, the reflected portion of a ray of light is much greater when the new medium is, for instance, mercury than when it is, for instance, water or glass. But, apart from these differences, the rule is that the amount of light which is reflected in the case of any given medium is, in general, greater as the angle of incidence is greater. This, in ordinary language, means that the more obliquely the light approaches the surface, the greater is the amount of it which is reflected. In the case of surfaces which do not scatter the light, the portion of the ray which is refracted—that is to say, passed through after bending—consists of all that is not reflected. Hence it follows that the refracted portion of the ray in such cases diminishes as the angle of incidence increases.

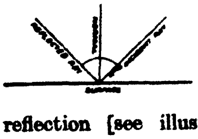
Scattered Light. Now before we go on to consider the laws of reflection from smooth surfaces, we must dismiss that irregular reflection from irregular surfaces which is called the scattering of light. In such cases "the common surface of the two media becomes illuminated and behaves as if it were itself a source of light, sending rays in all directions" (Tait). Ground glass affords a familiar instance of a substance which scatters in all directions the light that falls upon it. Thus, when a piece of ground glass is interposed between the eye and a source of light, the light is scattered at the surface of the glass, which becomes visible at every point, while the form of the source of light can no longer be detected. We have already seen that such glass would be technically described as translucent, and we now see that translucence depends upon the scattering of light. When light falls upon an opaque body, the surface of which is not polished, it is reflected and scattered. Hence all points of the reflecting body are visible to the eye, notwithstanding what we shall afterwards come to recognise as the *laws of reflection*. The action of these laws presents a similar result when the surface of the body is polished. In such cases the surface may become quite invisible, as, for instance, when one walks into a mirror by mistake; or it may be visible only if the eye be placed at a certain point. The best description of the scattering of light and its relation to reflection is given by the late Professor Tait, one of the greatest physicists of the nineteenth century, and the coadjutor with Lord Kelvin in the production of the greatest of all works upon physics. We will, therefore, quote his authoritative words. He calls the paragraph which we quote the "*Visibility of non-luminous objects.*"

Visibility of Non-luminous Objects. "It is by scattered light that non-luminous objects are, in general, made visible. Contrast, for instance, the effects when a ray of sunlight in a dark room falls upon a piece of polished silver and when it falls on a piece of chalk. Unless there be dust or scratches on the silver you cannot see it, because no light is given from it to surrounding bodies, except in one definite direction, into which (practically) the whole ray of sunlight is diverted. But the chalk sends light to *all* surrounding bodies from which any part of its illuminated side can be seen, and there is no special direction in which it sends a much more powerful ray than in others. It is probable that, if we could with sufficient closeness examine the surface of the chalk, we should find its behaviour to be of the nature of reflection, but reflection due to little mirrors inclined in all conceivable aspects, and at all conceivable angles, to the incident light. Thus, scattering may be looked upon as ultimately due to reflection. When the sea is perfectly calm we see in it one intolerably bright image of the sun only; but when it is continuously covered with slight ripples, the definite image is broken up, and we have a large surface of the water shining by what is virtually scattered light, though it is really made up of parts each of which is as truly reflected as it was when the surface was flat."

The Laws of Reflection. The first law of reflection is as follows: When light is reflected from a surface, the incident rays of light, the normal to the surface, and the reflected ray of light, are all in the same plane.

By the normal to the surface is meant a straight line drawn from the surface at the point where the light strikes it, so as to be perpendicular to the surface.

The second law of reflection states that the angle between the incident ray and the normal is the same as the angle between the reflected ray and the normal; or, in more familiar language, the angle of incidence is equal to the angle of reflection [see illustration]. These two laws



may be stated in another form. The angle of incidence and the angle of reflection are equal to one another, and in one plane. Or, in yet other terms, if light be reflected from a plane surface, the incident and reflected rays are in one plane with, and are equally inclined to, the perpendicular to the reflecting surface at the point of incidence.

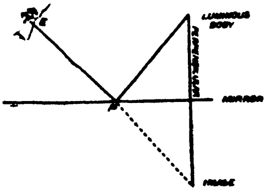
Explanation of the Laws. These laws are abundantly capable of experimental demonstration. Says Professor Tait: "The best experimental proof of the truth of this statement is deduced from the use of a reflecting surface of mercury in observations with the mural circle. The graduation of such an instrument is the most perfect that human skill can accomplish, and no one has ever been able to find by it the slightest exception to the preceding statement."

A phrase in the above quotation must be explained. In order to ascertain the height of a star above the horizon, or its altitude, astronomers often use a telescope which can work on a vertical circle, the graduation of which is as delicate as Professor Tait asserts. Such observations can demonstrate the truth of the law, since part of the operation consists in the observation not only of the star directly, but also of the image of the star in a bath of mercury, having a horizontal surface, to which the telescope is pointed after it has been pointed directly at the star itself.

Now what is the theory of light which will serve to explain these laws? In point of fact, they could readily be explained on Newton's corpuscular theory of light. We have merely to assume perfect elasticity on the part of the corpuscles, and the laws of reflection would be obeyed. The corpuscles would bound from the reflecting surfaces exactly like billiard balls from a cushion. But though the explanation is not quite so obvious, these laws of reflection are absolutely compatible with the wave motion or undulatory theory of light. It would take up too much space and require a certain amount of geometrical knowledge, which must not be assumed, in order to go into the details of this explanation; but the reader can draw for himself an interesting diagram showing what must happen when a wave, no matter whether of light or of sound, obliquely strikes a surface and is reflected from it. The wave, of course, must be drawn as having a wave front—a plane wave front—which can be represented by a straight line, moving forward in a direction at right angles to itself.

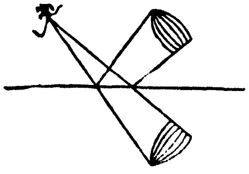
The Law of Least Time. From the laws of the reflection of light, it follows, according to what is known as *Fermat's law*, that the path taken by a ray of light, once reflected on its course between two points, is that which can be travelled over in the least possible time. This can be stated more comprehensively thus: If a ray pass from one point to another, after any number of reflections at fixed surfaces, the length of its whole path from one point to the other is the least possible—subject to the condition that it shall *meet* each of the reflecting surfaces. "For the point in a given plane, the sum of whose distances from two given points (on the same side of the plane) is the least possible, is that to which, if lines be drawn from the points, they are in one plane with the normal or perpendicular to the given plane, and make equal angles with it." The reader should draw a diagram to illustrate this. In association with this law we must always have in our minds a further law, which can here be merely asserted, though it is implied in Fermat's law—that when a ray of light, or, indeed, any form of wave motion, is refracted or bent when passing from one medium into another in which it has a different velocity, its path from any point in one medium to any point in the other is always shorter than any other possible path. It is the shortest possible path. It might be thought, of course, that the straight line between the two points would be the shortest path. It is, of course, the shortest in length, but not the shortest in time. It is inferior in this respect to the bent path which the ray actually takes when, for instance, it passes from air to water. Less time is occupied in traversing this path, since a higher proportion of the total time is devoted to the passage of the light through that medium which permits of the most rapid propagation. In the instance we have quoted, this medium is, of course, the air. Similarly, it saves time to go a little out of one's way *on a motor 'bus*.

Formation of Images. When the eye perceives an image in anything—as, for instance, that of a candle—as the result of the reflection of light from a plane surface, it is always deceived, precisely as the ear is deceived by means of an echo. The information given us by the eye depends merely upon what immediately reaches it. It can tell us nothing whatever of the previous history of the light, any more than the ear can tell us the history of a sound wave prior to its reflection from an echoing surface. When we look at the image of a candle in a flat mirror we can state a simple law which enables us to locate exactly the position of that image and its relation to the objects imaged. "The image of any point in a plane mirror is found by drawing from the point a perpendicular to the mirror and producing it till its length is doubled" [see illustration]. The drawing will make the statement of the law appear as simple as it really is. In such a case the eye, of course, is completely deceived. It seems to see the object in the depths of the mirror, and the image thus formed is called a *virtual image*. Another way of finding it is, of course, to produce the line E—P until it reaches the point already ascertained, by drawing and doubling the perpendicular from the luminous body to the mirror. Rays proceeding from the luminous body behave, after reflection, just as if they came from the image found in the way we have described.



Real and Virtual Images. Such an image as this is called a *virtual image* because only the reflected rays appear to come from it. It is only their directions produced backwards in imagination that lead us to it. There are real images, however, which are so-called because the rays of light have actually passed through them.

The case is only very slightly complicated if for the luminous point we substitute a body of some size, which, of course, consists of an infinite number of luminous points, each of these behaving according to the laws already stated. Light coming from any point of this object and reflected in the mirror will appear to come—to vary the words we have previously used—from a point so placed that the line between it and the actual point is bisected at right angles by the mirror. Such a virtual image is reversed, as is, of course, known to everyone who has ever looked at himself in the glass, and as may be shown very strikingly by attempting to read the reflection from a printed page in a mirror, and then by holding up to a mirror a piece of blotting-paper which has just been used. The accompanying diagram will readily show why the image must be reversed.



Mirror-writing. Since it is well to co-ordinate our knowledge, we may here comment upon that extraordinary form of writing which in certain nervous disorders is executed from right to left, so that when it is reflected in a mirror it looks like ordinary writing, and when looked at directly it is identical with the marks which ordinary writing would make on blotting-paper. It is always written with the left hand, and in many cases the patient is totally unaware of any peculiarity in the writing. One patient "wrote letters to her friends in mirror fashion and was surprised she did not receive answers from them." A certain number of perfectly healthy persons, when asked to write with the left hand, write mirror-wise, and it is recorded that one of Leonardo da Vinci's manuscripts is thus written, while we know that in his later years his right hand was paralysed. We shall not here attempt to explain mirror-writing. It is an extremely puzzling phenomenon, and can by no means be readily explained. Some of the facts we have quoted seem to show that the patients see the writing in different fashion to ourselves, and this introduces us to a subject which, though not usually considered in this place, if dealt with at all in the textbooks, is yet properly given attention here.

Retinal Images. Having spoken of real and virtual images, having noted how, in certain conditions, images are inverted, and having described the extraordinary peculiarity of vision which is exhibited by many mirror-writing patients, let us ask ourselves the most interesting of all the questions which are concerned with sight. In due course we shall discuss the eye as an optical instrument—incomparably the most wonderful of all optical instruments, notwithstanding the remark made by Helmholtz, though quite unworthy of him, that "if it were sent him by a scientific instrument maker, he would promptly return it as grossly defective." Owing to an extremely simple fact, all the images which are formed upon the retina are inverted. The eye contains a doubly convex lens, and the consequence of the passage of the rays of light from any object through it is to cause an inverted image to fall upon the retina. This fact is quite beyond dispute. Thus, in the case we have described, where, by reflection, an inverted and virtual image reaches the eye, that inverted image is reinverted so as to form a non-inverted, or upright, image on the retina. But while we interpret an inverted image as not inverted—that is to say, while we do not see things upside down, even though the images of them in our eyes are upside down—yet in this case the re-inverted image is interpreted by us as if it were once inverted. We see a tree reflected in water as if it were upside down, and the tree itself as if it were right side up, yet in point of fact the image of the tree itself is upside down upon the retina and the image of its reflection in the water is right side up upon the retina.

We See Everything Upside Down. When this fact of the constant inversion of every retinal image is first presented to the consideration of the student, he usually finds it absolutely incomprehensible—and no wonder. As long as we confine ourselves to physical conceptions, it is incomprehensible. What else can be said of the two facts, each true in its own sense, that we see everything upside down, and that, notwithstanding, we see everything right side up? In order to understand this paradox it is necessary to seek the help of psychology. The young student begins physics before he is aware, perhaps, of the existence of psychology, and certainly long before he suspects that there may be anything intelligible and interesting in it. Why do we not make the most ludicrous mistakes, he asks, if we really see everything upside down? And this question leads to an explanation which seems, at first sight, plausible. Perhaps, though we really see everything upside down and with its right side on the left—perhaps, though every retinal image is inverted, we are saved by experience. The sense of touch is not similarly deceived, and by gradual years of education we learn to allow for the deception which our eyes would seek to practise on us. When the young thinker has reached this point there will occur to him, it is to be hoped, a possible means of testing his supposition. Let us suppose the case of a person born blind, owing perhaps to some opacity of the lens of the eye. Suppose, now, that by the time he has reached adult life, surgery has so far advanced that the opaque lens can be removed and an artificial lens of glass substituted—not inside the eye, of course, but in front of it. Will such a patient be astonished to see everything upside down, and will he only gradually learn by experience to correct his impressions? Will his case, indeed, be something like that of the boy who learns to shave himself before a mirror and who gradually learns to allow for the difficulties ?

Our Eyes are at the Back of our Heads. The answer is that in such cases the patient does not see things upside down. He is not deceived even at the first. That explanation is not tenable. The true explanation is that our whole conception of what constitutes the act of vision needs *revision*. We have not yet thought about it in any real sense. We are thinking of mind in terms of space. But space or extension is not a property of the mind. We have unconsciously formed a sort of notion of the mind, or thinking subject, as standing upright somewhere behind the eye and looking at the inverted images which are thrown upon the retina at the back of the eye. This, however, is quite false and ludicrous. In point of fact, it is perfectly well known that the images formed upon the retina lead to certain stimulations of the optic nerves ; that these pass backwards from the two eyes to certain intermediate cells near the under-surface of the brain ; that from these there pass new fibres, which convey the nerve impulses right through the substance of the great brain or *cerebrum*, to its hindmost part, where the vision centre lies.

Everyone's veritable eyes are thus in the back of his head. Somewhere in the wonderful cells of the vision centre, which lie in the grey matter covering the occipital lobes at the extreme posterior aspect of the brain, these nerve impulses are appreciated in the form of vision. There is no one standing and looking at the inverted images upon the retina. No terms of space, up and down, right and left, are applicable to the actual act of vision. As long as the retinal images show a consistent correspondence to external reality, the perceiving subject is not deceived. It matters absolutely nothing to him whether the image of a man standing on his feet is erect or inverted, provided that it is always one or the other, so long as the man stands on his feet, and is always reversed if he stands upon his head. All this may seem very mysterious and inexplicable, but the reader must try to believe that this is not our fault. Every fact of consciousness is ultimately mysterious and inexplicable, but the mere fact that we see things upright when the images of them on the retina are inverted offers no difficulty at all to anyone who has once grasped the fact that the act of conscious perception cannot be subjected to terms of space — terms derived from the physical world.

Self-education. And here we may be permitted a brief digression. It is commonly but blindly supposed that the function of a teacher is to instruct, to impart facts, to disseminate knowledge. But this is not so. Every teacher who has any real title to the name is not an instructor, but an educator. We may, indeed, hope that the reader has not gone so far along the courses which this publication provides for him without discovering the difference between instruction and education. If space availed, we might write a whole chapter—a chapter which we believe would be of real value—upon the title of this publication. It might have been called and conceived "The Instructor." In such a case the writers would have spent their time in setting down every fact they considered valuable in the best possible order, for the purpose of making them easily memorable. Many publications of this kind exist, and have their valuable function. One cannot do without a dictionary, an atlas, a gazetteer, and so on. These are all necessary instructors. No publication could properly be called a self-instructor, since one cannot instruct one's self.

The Business of a Self-educator. You cannot evolve facts out of your own inner consciousness, or at least any facts save those of your consciousness itself. But while a self-instructor is impossible, a self-educator is possible, and is the only possible educator. No one is self-instructed, not even the wisest. Even if he be a discoverer and a pioneer, Nature is his instructor. But every educated man is self-educated, and there is no other kind of education. All that the true teacher can do, or wants to do, is to help a man to educate himself. For this purpose the teacher must also be, up to a point, an instructor. But if he be really an educator he does not impart facts for their own sake at all ; he uses them merely as illustrations, merely as arguments in favour of the views which he lays before the reader, and which he asks the reader not to accept, but to consider for himself. Of course, we all have to take the greater part of our beliefs upon authority. Whenever possible, the present writer quotes the exact words of the workers who have first demonstrated the facts which he discusses. But none of these workers wishes his words to be accepted on his authority. There is no authority but truth. If this were an "Instructor" we might ask the reader to accept certain statements here made on our authority, just as he accepts the spelling of a word on the authority of a dictionary. But this is a *Self-educator*, and the reader will not pay us the compliment we most desire if he quotes any assertion and says: "It is so stated in the SELF-EDUCATOR." If this publication is to be worthy of its name, it must not merely teach the reader certain accepted facts, as any instructor might do, but must teach him to think for himself as only an educator can do, and must thus justify its title of SELF-EDUCATOR.

Real Education. The present writer has kept these principles firmly before him from the first. Again and again he has deliberately sacrificed the statement of facts of greater or less importance in order to gain space for attempts to be suggestive and stimulating, or even irritating, to the reader's own thinking apparatus. It was, and still is, the practice of one of the writer's teachers to ask his class an interesting question and deliberately decline to give the answer. Weeks or months later he turns suddenly upon one of his students and demands the results of his thoughts on the subject. So much the worse for him if he has not thought about it at all. This is real education, not a cramming of the mind with facts, but a drawing forth of its own inherent powers. Such a plan can scarcely be adopted in a written work, but one is often tempted to try to do so.

Teaching to Think. The subject which has led to this long, but we hope not useless, digression, is a case in point, and the writer has more than once been successful in causing an intelligent boy to think it out for himself. Draw a simple diagram of the eye for such a boy, show him how the image of every object of vision is necessarily upside down upon the retina, and ask him how in the world it happens that we nevertheless see things right side up. If you have interested him and he tries to think it out, you will find that there first of all suggests itself to him the explanation to which we have referred—the idea that the experience of other senses, such as that of touch and hearing (in the case of the image of a speaking individual), enables us to correct the erroneous impressions derived from the retina. When this explanation is offered, reply that he is right to have thought of it, but that observation has shown it, as we have seen, to be inaccurate. Ask him to "think again," and tell him a little more of the paths of vision that lie outside the eyeballs altogether. Then very likely he will come to realise that he must revise his whole manner of thinking and must not imagine the perceiving mind as a sort of material shape, standing and looking in a certain position. If he still retains the notion that the perceiving mind is a kind of very minute man standing upright and looking at the inverted image upon the retina, ask him why, for all he knows, this little man should not himself be standing on his head, in which case the inverted image would be righted. This is the suggestion which the present writer has found most effective in removing a difficulty of understanding which at first seems insuperable.

We need not further apologise for reminding the reader that this publication is not an instructor but a self-educator, and that our business is therefore not to instruct the reader, but, if possible, to help him to educate himself. We may quote from the words of Sir Norman Lockyer, formerly President of the British Association, and now president of the recently formed British Science Guild, the object of which is to bring home to a sleepy public the importance of true science and of true education. Sir Norman says: "One thing we are agreed upon is the necessity of the best system of education both for the school and the workshop—that is, instead of instruction, learning things by rote, we want *education*, teaching men and boys to think. Instruction is often the bane of education."

Images in Several Mirrors. And now, after a digression for which we have long sought an opportunity, let us return to the Formation of Images.

Various interesting complications arise if more mirrors than one be used, but however much the images be multiplied, the laws of reflection are always accurately observed. Says Professor Tait, in reference to a phenomenon which some readers may have seen amusingly illustrated at a recent Earl's Court exhibition:

"The principles already stated suffice fully for the explanation of the curious vistas of images formed by two parallel plane mirrors facing one another at opposite sides of a room. The only additional observation necessary on this subject is that, if the mirrors are silvered on the back, the light at each reflexion has to pass twice through the glass. Thus, if the glass be pinkish or greenish, the various images are more and more coloured as they are due to more numerous reflexions."

The Kaleidoscope. There is a celebrated scientific toy, invented by Sir David Brewster about the year 1815, which illustrates the principles of reflection in two or more mirrors; this is known as the kaleidoscope. We need not go into the details of its mechanism, since they illustrate no new principles. It consists essentially of two plane mirrors which are inclined to one another at an angle of 60°, this being taken as the most convenient fraction of 360°. It can be proved that, in order to form a symmetrical picture, the angle at which the mirrors are inclined to one another must be an exact submultiple of two right angles; or, in other words, an even submultiple of 360°. If the angle between the mirrors does not conform to this, a symmetrical figure cannot be produced. If it does, a symmetrical picture is yielded by objects placed in any position between the mirrors.

In the ordinary kaleidoscope the mirrors consist of two long strips of thin glass inclined at the requisite angle to one another, and placed within a cylindrical tube, through one end of which the observer looks, while at the other end is a box with glass walls containing pieces of coloured glass, etc., placed so as to lie in any position between the mirrors. Since reflection is never perfect, the various sectors, or parts of the symmetrical picture, produced are not equally bright, but this does not detract from the beauty of the patterns.

In order to study the theory of the instrument a kaleidoscope may be formed in such a fashion as to permit of alteration at will of the angle between the mirrors. It can then be shown that it is necessary, as may also be proved by abstract considerations, for the angle between the mirrors to conform to the condition we have named.

Similar pictures may be produced by three mirrors, enclosing a triangular opening. They must be arranged so that each angle is an even submultiple of 360°; while, of course, if they are to be arranged in a triangle, the sum of the angles must be equal to two right angles or 180°. Three such arrangements are possible. If four mirrors be used they must be arranged in the form of a square, or at any rate a rectangle. Kaleidoscopes cannot yield regular figures with more than four mirrors, since the angles which would then be made between them could not conform to the necessary conditions.

TAILORING FOR MEN

The Start. Choosing Material. Style, Measurements, and Tool. **The Drafting. Materials Required. Stitches. Stretching and Shrinking**

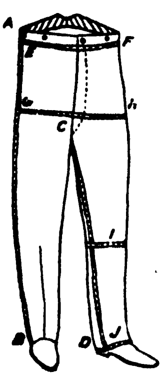
By W. D. F. VINCENT

THERE are at least three distinct courses of study that have to be taken up by the young man who aspires to be a thoroughly qualified master tailor. He requires a knowledge of the practical or sewing part, the scientific or cutting part, and the commercial or business part.

Some little difference of opinion exists as to what is the proper order in which to take these. The old method was to serve a long apprenticeship to the sewing, then take lessons in cutting, and leave the business side to be picked up by actual experience—a plan which often led to the Bankruptcy Court, despite considerable technical ability. The more modern plan is to enter an academic course at some such institution as the "Tailor and Cutter" Academy, and there take lessons in all three sections simultaneously.

Assuming the customer has presented himself, the first step is to take the order, and here the skill of the tailor begins.

Selecting the Material. The material should be in harmony with the requirements of the customer, bearing in mind his occupation, form, and complexion. For wear-resisting purposes, cheviots, tweeds, and serges may be recommended; for dress garments, thinner, softer, and finer finished cloths are best. For business and professional wear, black coats and vests, and neat, striped trousers are generally most suitable. For farmers, builders, etc., neat drab tweeds of rather a heavy make, and not too rough, are the most appropriate.



1. MEASUREMENTS

For sportsmen, Harris tweeds and checked cheviots are very popular, and make up into stylish garments. Stout men should be dressed in dark colours, and plain or very small-patterned cloths. Checked cloths make men appear wider without increasing the appearance of height in proportion; and if checks are woven irregularly, as is sometimes the case, they give a lopsided effect which is anything but attractive. Stripes, whether in the pattern of the material, or produced by seams, stitchings, braidings, etc., add to the length or width of the figure in the direction in which they run.

Dark complexions are best suited by those shades in which reds and yellows play an important part—as, for instance, russet brown, drab, etc. Fair people are best suited by blues, and those shades in which blue plays an important part.

Sell your customer material adapted to his requirements on these lines, and then proceed to get particulars of style.

The Style. This includes the shape of the garment and its general finish, and here the tailor will receive great assistance from fashion plates.

Do not attempt to put a man with old-fashioned ideas into the latest cut; discretion, tact, and judgment must be exercised, or the result will be bad. Find out what your customer wants, and then advise him judiciously; and having determined the style, carefully book the details of his order as it relates to pockets, time for trying on, finish, price, etc., together with the number of the material, and then proceed to take the measures, beginning with the trousers.

Measurements. A to B, full length of side, say, 44; C to D, full length of leg, say, 32; E to F, circumference of waist, say, 30; G to H, circumference of hips or seat, say, 36; I, size of knee required, say, 18; J, size of bottom required, say, 17 [1].

It is seldom wise to give less than 12 in. extra length to the side than the leg. Avoid taking the waist measure tightly. Take the size of seat in harmony with your customer's idea of fit.

Cutting Tools. We now take our cutting tools—*viz.*, inch tape, square, chalk, shears, and, if possible, a trouser stick. Take the cloth from which the garment has to be cut, notice if there is a way of the wool, and if so arrange for the pile to run down. If there is a string in the selvedge, it indicates a flaw in the cloth which must be avoided in the cutting. [This point will be dealt with more fully later.] The cloth is cut double, and in order to cut for the right and left sides this is arranged face to face. As a rule, trousers are drafted direct on the cloth in this way:

The Drafting. 1—2, the selvedge edge of cloth; 1 to 2, the length of side = 44; 2 to 3, the length of leg = 32; 3 to 4, one-sixth seat = 6; 2 to 9, one-fourth bottom = 4¼ [2].

Draw line from 9 to 4, and by it square across to 3. Square by line 4 to 9 across to 6; 4 to 5, one-twelfth seat = 3; 4 to 6, one-sixth seat plus ¼ = 6¼. Square up from 5 by line 5 to 3 (which is at right angles to line 4–9). Square across from 7 to 1; 13 is one-sixth seat plus 4 in. up from 5 = 10; 13 to 14 one-fourth waist plus ½ in. = 8 in.

Spring out a little above 14, and round out to side line about 3 or 4 in. up from 3; 4 to 8, half leg length less 2 in. = 14; 8 to 10 and 8 to 11 are each one-fourth knee = 4½; 9 to 12, one-fourth bottom, less ¼ in.

Complete outline of top sides as shown. Hollow over the fronts about ¾ in. for a 17 bottom, more for a smaller and less for a larger bottom.

The top sides are then cut out, a "turn-up" of from 1 in. to 1½ in. being left at the bottoms. The "dress" is cut out from the right side as follows: 6 to 15, 1 in., curve up to fly line and down to leg seam as shown.

THE UNDER SIDE. Lay down the cut-out top side and proceed as follows:

6 to B, 1½ in.; 10 to C, 1 in.; 12 to D, 1½ in.; 5 to A, one-fourth seat less 1 in. = 8. Draw line from 6 through A [3].

13 to 14 and F to G together equal half waist plus 2½ = 17½. L to M and H to J together equal half seat plus 2 = 20.

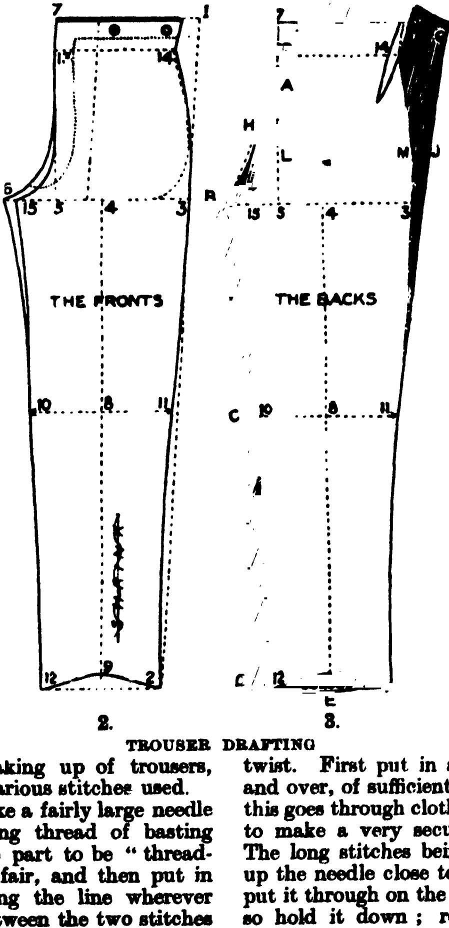
Square across from 1, then place square on seat seam and square across to G.

F. to K, 2 in.; K is 1½ in. above the line.

Take out fish 1 in. wide, about 3 in. from G and about 6 in. deep.

Cut from the cloth, leaving from 1 in. to 1½ in. inlay at the bottom for turn-up, about 1 in. up the side seams and 1 in. up the seat seam for inlays. Some also leave an inlay at the top of leg seam. Snip the side seams of top and under sides at knee on both leg and side seams to facilitate their going together fairly in the making up. Put sufficient cloth in to make pocket facings, fly, etc., and proceed with the trimmings.

Materials for Trimmings. ¾ yd. pocketing; ¼ yd. silesia to match; ⅜ yd. linen to match; ⅛ yd. striped silesia for waistband lining; ¼ yd. canvas; 7 large and 5 small buttons; 1 yd. of twist to match; a skein of silk; trouser binding, 6 in. over the waist measure; sundries according to details of order.



2. 3.

TROUSER DRAFTING

Stitches. In the making up of trousers, we have to consider the various stitches used.

THREAD-MARKING. Take a fairly large needle and thread it with a long thread of basting cotton, double. Take the part to be "thread-marked," see that it lies fair, and then put in long stitches exactly along the line wherever there is an inlay. Cut between the two stitches and pull the thread along so as to leave only sufficient cotton for the purpose as shown in 4; now separate the top layer from the lower, and cut through the stitches, thus showing the exact quantity of inlay on either side.

BASTING. The basting stitch is simply a long fore or running stitch, and is used to put the various parts together previous to the machine stitching. This is known as tacking by dressmakers, and is illustrated on page 150. The basting stitch shown there is a form of this stitch, which is used for keeping two or three layers of materials in place.

BACKSTITCHING. This is the most important stitch used in tailoring, as well as the strongest. The thread enters the cloth at 1, travels through to the other side and up at 2, it enters again at 3, and comes out at 4, enters at 5, and comes out at 6, enters again at 2, and so on, the full length of the seam [5].

BACK AND FORE STITCHING. This stitch is used when it is desired to get over the work speedily. It consists of one back stitch and one fore stitch, alternately; thus it enters at 1, comes out at 2, goes back to 3, comes out at 4, goes on to 5, comes out at 6, and then goes forward to 7, out at 8, through to 9, and then back to 7, and so on, as indicated by the arrows [6].

FELLING. There are various styles of felling, one being that shown on page 150; the form generally used by tailors is that shown in 7. The needle is inserted in the under material quite close to where it has come out on the upper material; it is then brought forward the length of one stitch and brought close to the edge of the upper material, thus enter cloth at 1 close up to the lining, come out of lining at 2 close up to the cloth. This is used for securing lining, etc., to the main part of the garment.

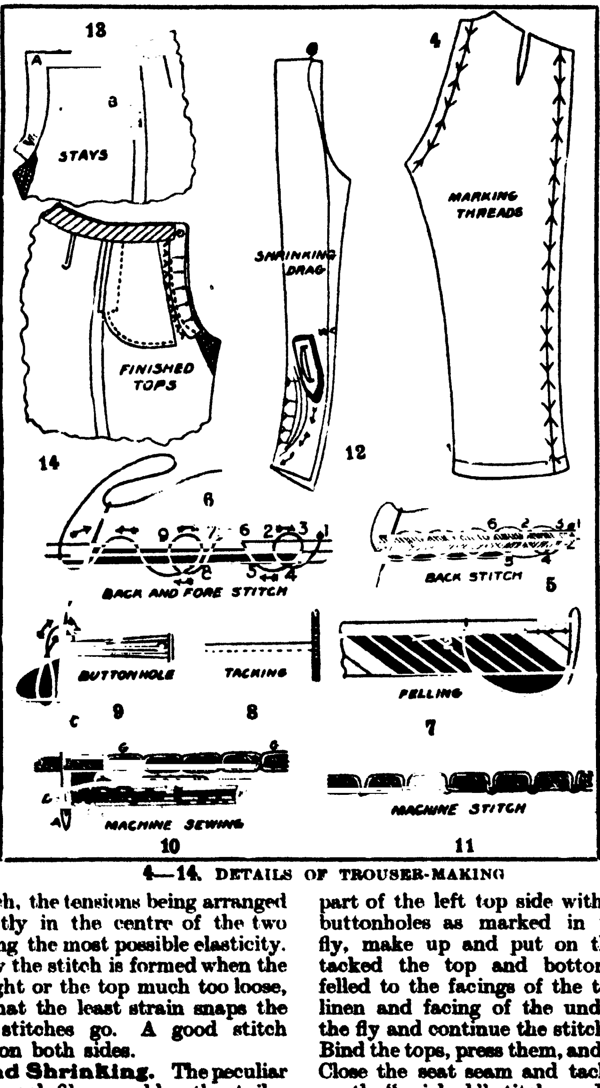
TACKING. Various forms of this stitch are used by tailors; we merely give the style mostly used for pockets. It is generally done with twist. First put in at least three stitches over and over, of sufficient length, say, ½ in. to ¾ in.; this goes through cloth and linen, and its object is to make a very secure ending to the pockets. The long stitches being put in, proceed to bring up the needle close to the end of the tack, then put it through on the other side of the twist, and so hold it down; repeat this as regularly as possible until the entire length of the tack has been covered with these over and over stitches [8].

BUTTONHOLE STITCH. The buttonhole being cut of the correct length, first put in a bar thread either of gimp, four-cord thread, or double twist, as shown by the double line. Now start from the left-hand end of the top side, insert the needle close up to the end, and then bring the twist up and cast it over the needle from left to right, and draw the needle up at such an angle as will raise the "purl" the desired amount. The stitches in a buttonhole should be regular both in depth and width, and the hand should always be drawn up at the same angle so as to retain regularity of "purl." The stitches at the eye may be a little closer together, and the "purl" brought a little higher than the other parts. · The end of the hole is finished with three over-and-over stitches and three "purl" stitches just over these; they are then drawn together and pressed, the edges being *bitten* up to make a good finish [9].

MACHINE SEWING. Of the various kinds of stitches made by sewing machines, the lock stitch alone needs comment. The machine stitch is made by the twisting or interlocking of two threads, and great care is necessary in the adjustment of the tensions of the two threads to ensure getting the machine stitch at its best. It is illustrated in 10. C is the needle, with eye near the end, carrying a thread A. B is the double thickness of cloth to be seamed, D is the nose of the shuttle with thread coming out of the top at E, F shows the last completed stitch, the tensions being arranged so as to cross exactly in the centre of the two layers, thus ensuring the most possible elasticity. In 11 we show how the stitch is formed when the lower tension is tight or the top much too loose, the result being that the least strain snaps the thread, and the stitches go. A good stitch appears the same on both sides.

Stretching and Shrinking. The peculiar formation of the wool fibre enables the tailor to stretch or shrink different parts of the cloth by the use of moisture and a hot iron. This is employed in various parts of garments, but in trousers it is principally used at the bottom of the top sides and the thighs of the under sides. The principle is the same wherever it is used. Fold the cloth over at the part to be shrunk, wet it, and then bring it round so that the cloth forms puckers. Then apply a sharp iron, and work it round as shown by the arrows on 12 until the form desired has been imparted. The under part shrinks most, and to get both sides alike it should be turned over and the operation repeated.

The Making. First mark up the inlays with marking threads, then shrink the bottoms—some tailors do this before they are seamed, others do it at a later stage. Put in the stays for the pocket in top side, and stitch the mouth about 6 in. deep. Put a piece of linen on the fork of top side [13]. Now baste the seams, keeping the balance marks together; seam them together either by hand or machine, but always seam five or six inches down from the top of leg by hand; press open the seams and put linen stays on for the pockets at B, at the back of the facings that have been sewn on at that part. Put canvas round the top, as at A, seam on the button-catch on the right side to within 2 in. of the fork, and put linen down the back of this to take the buttons.



4—14. DETAILS OF TROUSER-MAKING

Now make up the fly, and line the front at that part of the left top side with silesia. Work five buttonholes as marked in 14. Baste up the fly, make up and put on the pockets, having tacked the top and bottom. The pocket is felled to the facings of the top side, and to the linen and facing of the under side. Stitch on the fly and continue the stitching round the tops. Bind the tops, press them, and sew on the buttons. Close the seat seam and tack the fly with some neatly "pricked" stitches. Press the seams, put on the waistband and crutch linings, and then turn up the bottoms, making the length of leg to measure. The trousers are now ready.

UNITY OF THE BRITISH ISLANDS

The Celtic Fringe. A Survey of the Beginnings and Evolution of the Peoples of Scotland, Ireland, and Wales. Their Rulers and Early History

Continued from page [illegible]

By JUSTIN McCARTHY

IT is time that we should take some account of the countries which have been, almost as far as authentic history goes back, regarded by the world in general as associated in locality, in dealings, and in destiny, with the history of England. We may begin with Scotland.

Scotland. We learn something of this region from Roman records and especially from the writings of Tacitus, the Roman historian, who died nearly a hundred years before the Christian Era. The Romans gave the name of Caledonia to that part of Scotland which was north of the Wall of Antoninus. More recent accounts, some of them recorded by the Venerable Bede, tell us that this region was made a place of settlement by an invading tribe from Ireland, who gave it the name of Scotia. The earliest invaders of Caledonia appear to have been Celtic tribes called the Scuths, or Scythians, who were later known as the Scuths or Scotti. The Scotti, who passed to Caledonia from some parts of the coast of Gaul, drove the Caledonians and the Picts, who are by some historians said to have been the earliest inhabitants of Scotland, into the north of the country, and according to these authorities it was from the names of the invading Scotti that the inhabitants of that part of the country, and afterwards of the whole of the northern region, came to be designated Scots.

The Romans under Agricola invaded Caledonia some eighty years after the Christian Era; and the Wall of Antoninus was built to secure the Roman conquests at a later period.

The Scottish Line of Kings. We may pass rapidly over these early developments of Scottish history. The Norwegians invaded Scotland; the Danes also made invasion but were finally driven out. The Northern Scots had kings of their own. One of these was Duncan I., grandson of Malcolm II., whose name has been made to live for all time, not by chronicle or history, but by the drama. Duncan I. was murdered by a kinsman of his named Macbeth, whom Shakespeare has made immortal. Macbeth was, according to chronicle as well as to Shakespeare, defeated by the rightful heir to the throne who had the assistance of Edward the Confessor, and Macbeth himself was killed by Macduff at Dunsinane. The battle of Waterloo is hardly more of a reality to the modern mind than this struggle at Dunsinane has become through the genius of England's greatest poet.

There were many struggles afterwards between England and Scotland, and the Scots resisted for a long time the attempt of the English sovereigns to make one common kingdom of the two countries. The English language began to spread itself through the southern parts of the Caledonian region, and the south of Scotland appeared to be fairly on the way to incorporation with the north of England. For a time, indeed, it seemed as if the tendency were for Scotland, as a whole, to accept the overlordship of the English rulers according to the system which, as we have already said, prevailed for the time between the most powerful monarch of England and each of the minor sovereigns, who still claimed rule over separate dominions. Scotland came, however, before long to establish a royal line of sovereigns whose supremacy was generally acknowledged among the Scottish people.

English Settlement in Scotland. Malcolm III., known as Malcolm Canmore, the eldest son of the Duncan whose reign was brought to an end by Macbeth, proved himself after the defeat and death of the usurper to be one of the most powerful and most beneficent rulers Scotland had ever known during her existence as a separate kingdom. Malcolm came to the throne in 1057 A.D. He had lived for a long time in England, had married an English Princess, Margaret, the sister of Edgar Atheling, and this marriage led to the settlement of a large number of English residents in Scotland; to the spread of English commerce and the English language there, and to a friendly feeling, for the time at least, between the people of the two countries.

This tendency of Englishmen to settle in Scotland and to spread their trade, their business, and their language there was much increased by the many severe and almost despotic measures introduced by William the Conqueror into his English kingdom with the support of his Norman followers, measures which, as we have already seen, were felt to be oppressive in many parts of his dominions.

Malcolm III. Malcolm Canmore appears to have been a man of generous character, with an understanding much in advance of most of the rulers belonging to his day. It was his constant endeavour to maintain, as far as possible, the national usages of his country, and to promote the love for music and poetry, and culture in general which have always been characteristic of the different varieties of the Scottish race. He had also a strong desire to mould those different varieties of the people into one common nationality, and to maintain Scotland, according to its limits as then marked out, as one distinct and independent kingdom. In all his plans he was greatly assisted by the generous efforts, the attractive ways, and the thoroughly noble nature of his wife, who since she had become a Scottish Princess proved herself ever sympathetic with the Scottish people and their traditions. Wars were still frequently going on in those disturbed days; Malcolm himself was killed on the battlefield in the year 1093, and his wife survived him only by a few days. After their deaths the country, for a while, seemed to be growing more and more under English influence, but the union of the two kingdoms was yet very far off.

The Evolution of Caledonia. We shall tell during this course how the intervening period was marked by a succession of fierce struggles between the Scotch and the English, and how it brought to the front some illustrious Scotchmen, kings and military leaders alike patriotic, whose names will live for ever in history. For the present our purpose is to trace the gradual emerging of Caledonia from its dawn, through its legends and its traditions, into the clear light of distinct nationality and established historical record. An atmosphere of the poetic, and in a certain sense of the artistic, prevailed throughout the story of Scotland from its opening page. The physical character of the country, with its high mountain ranges, its lakes and its rivers, its caverns and its woods, all compressed into such narrow compass by the imprisoning waves of its great surrounding seas, seemed to mark it out as the natural home of the legend, poetry, and romance. For a long time its literature and romance, its poetry and its prose were mainly appreciated in Scotland itself, and were but little understood across what was then regarded as the English frontier. There was, indeed, a much closer sympathy between Scotland and Ireland, between Scotland and France, and even between Scotland and some parts of Germany—of the Teutonic races, that is to say—than between the Scottish people and their English neighbours. At the time which we have now reached in this history there were merely evidences—and only in its later days—prophetic of the great change which, after many fierce interruptions by warlike struggle, were to unite the two peoples under one crown and one state system.

The Story of the Irish People. The opening of the history of Ireland opens also the story of a race which for centuries seemed little likely ever to come into congenial union with the people of England. In the case of Ireland, as in that of Scotland, we have to rely on legend and tradition for much of the story which is now commonly and reasonably accepted as authentic, reasonably because what we learn from legend and tradition shows itself in full accordance with the national development described in genuine and authoritative record. The Irish people, like the Scotch of the Highlands, like the peoples of Wales, of the Isle of Man, and the northern parts of France, appear to have been of Celtic origin. But we have a large amount of literary lore in Ireland which would take us back to a still more distant age of the world's development. One of the treasured legends of Irish traditional lore is that which tells that the Phœnicians from the coast of Syria, the great navigators and explorers in the dawn of history, were the first strangers who made a settlement on the Irish soil.

Greek Settlers in Ireland. Another story tells that Ireland was occupied by a whole colony of settlers who came from Greece and are even now known in Irish history as the Tuatha de Danaan, a name still familiar and treasured in Irish romance and even in Irish history. This Greek race is said to have made its home in Ireland for many centuries. Of course we are not bound to accept this legend any more than that of the Phœnician settlement as a distinct and authentic part of Ireland's developing history; but it may be safely said that when such legends become part of the common belief of a people the probability is that they must have had something of reality to impress them thus on the national memory. Even the most practical historians see reason to believe that much in the national characteristics of the Celtic Irish during past centuries, and, to a certain extent, down to our own time, suggests the probability of an ancestry coming from some sunnier region than that of Ireland itself. The habits of the Irish peasant even in our own day suggest that he must at some time, however remote, have had an ancestry coming from a land where life was mainly passed in the open air.

The early literature of Ireland is saturated with ideas which seem to belong to lands where the supernatural and the miraculous are familiar to the life of the human being; and its popular story-telling concerns itself almost unceasingly with fairies and goblins, with supernatural visitations, and with haunted rivers, lakes, caverns, and mountain-sides.

The Milesian Masters of Ireland. As we follow the history of Ireland's development, we are told that the island was occupied by the Milesians, a people of eastern race who had been settled for a long time in Spain, and were in the course of their adventurous career taken by the desire to make themselves owners of Ireland. They invaded the island, defeated finally the descendants of the Phœnicians and Greeks who were still rulers there, and made themselves masters of the land. Then there came, according to this still legendary history, a struggle between two of the leading Milesian chiefs which ended in one of them killing the other and then declaring himself king of the whole country. The Milesian sovereigns who succeeded this first ruler are said to have been 118 in number, and a large amount of early Celtic literature, both poetry and prose, is devoted to their reigns.

Gradually we come to the Ossianic legends which tell of the adventures of Fingal, or Finn, as he is called more habitually in Irish story. In due course of time the Irish people seem to have divided themselves into a sort of communistic rule under the leadership of a number of elected chieftains, or sovereigns, and with a Druid priesthood, who before the days of Christianity undertook the religious teaching of the people—a religious teaching proclaiming somewhat vaguely the existence of a ruling spirit, the personality of which was typified for mortal eyes by the presence of the sun. The population was for a long time divided into septs or clans, the chief of each sept recognising the predominant authority of the chief elected to reign over the whole island. The Brehons, as the official judges and expounders of the laws were termed, were, as well as the chieftains and even the sovereigns, elected to hold their position. The authentic history of Ireland may be said to have begun with the time when Christianity took possession of the island.

St. Patrick. The first great name which comes up in Irish history after Christianity had begun to spread itself over the world is that of St. Patrick, the patron saint of the island. Patrick is said to have been, in his early youth, sent as a slave from Gaul into Ireland, having been captured by pirates engaged in the slave trade of those days. Even during his time of servitude he appears to have conceived a great affection for the Irish people. Long after, he made his escape to France, and from there to Rome, where he rose to a high place in the Christian Church. He returned to Ireland about the year 430 A.D., and began to devote himself to the teaching of Christianity there. Later on Ireland was invaded by the Danes, a race who, at that period, made themselves famous far and wide by their many daring and successful enterprises in invasion. The Danes were the rulers of Ireland for more than a century. Their rule came to an end, as most such foreign settlements do, by the rise of the one man whom nature seems to have destined for such a work. This man was Brian Boroihme, or Boru, brother of the king or chief of Munster, the southern division of the island, one of the most popular men in the country, whose name has given birth to a whole literature of history, romance, and poetry in Ireland. Brian had the genius of a soldier as well as of a statesman. He organised an army in 968 which completely defeated the Danes. That defeat was followed by another and another until the Danes were at last brought to a condition which made them willing to accept for the time the terms of the conqueror, and to content themselves with living in certain of the seaport towns, where residence was permitted to them so long as they made no effort at the reconquest of territory.

Brian as Ruler. Brian became convinced that his country would do better if united into one state under the rule of one sovereign than it could do under the rule of the separate chiefs. The whole course of his career fairly justifies the belief that his opinion was guided in this matter by purely patriotic considerations, and not by any ambitious desire to be raised to the rulership of the whole country. But this elevation naturally took place, amid the enthusiasm of the whole Irish people. Brian proved himself a wise, and, in every sense a most admirable ruler. He maintained peace and order throughout the whole land, and Irish literature is full of legends and poems which tell of the marvellous security prevailing throughout the whole island during his rule.

Brian had twelve years of a peaceful reign, then a rebellion was organised among those of the Danes who remained in Ireland, and the result was another invasion, Denmark seeking once again to conquer the island. Brian was now growing old, but he soon proved that he had not lost his courage and the military genius of his early days.

Ireland Divided into Provinces. He stirred up the whole country into energetic measures of defence, and took command of the forces himself. On the battlefield of Clontarf, ever since famous in Irish history and romance, he encountered the Danish army on Good Friday, 1014 A.D., and inflicted on it so crushing a defeat that it put an end to all peril of any further invading expeditions from Denmark. The battle was not gained without heavy sacrifice to the Irish cause, for Brian himself was killed after the struggle had long passed its turning-point. Brian, who was always careless of his own safety, assumed too hastily that the danger was all over when he had seen the Danish troops disperse in flight. He was recognised and killed by the Danish leader in his own tent, where he had gone to offer up a prayer of thanks for his country's victory. His death was in every sense a heavy loss to his country, for there was no one to succeed who could maintain supreme dominion over the whole island.

Ireland was once again broken up into four separate divisions, the provinces which we now know as Leinster, Munster, Connaught, and Ulster. The rulers of each of these divisions, while professing a nominal allegiance to the sovereign chief, governed their own states according to their own ideas, and there followed an era of civil war. Dermot Macmurrough, King of Leinster, carried off the wife of the Lord of Brefny. Brefny made war upon his betrayer, and Rory O'Connor, the last king of Ireland, espousing his cause, Dermot had to fly the country. He hastened to Acquitaine, where Henry II. of England then was, and doing him homage, asked his help. In response to his request some of the Norman barons, under the famous "Strongbow," invaded Ireland. Eventually, Henry II., becoming impressed with the idea that he was aiming at rivalry with him, recalled Strongbow, who returned to England and came to an understanding with the king. The result was that Henry himself led a great army into Ireland and, subduing all resistance, made the country a conquered part of his dominions. The history of Ireland is, from that time, associated with the history of Great Britain.

The Early History of Wales. Our course now brings us to the history of Wales. The Welsh people were known in the dawn of history as the Cymri, the word meaning "fellow countrymen," and the Welsh country was called by the Romans "Britannia Secunda," the words Welsh and Wales being merely gradual corruptions of phrases used by conquering invaders—Teutons especially—to describe anything foreign to them. After the Roman occupation of Britain had come to an end under the Emperor Honorius, Vortigern was elected king of that part of Great Britain which came more lately to be distinctly designated as Wales. Vortigern, as we already know, is said to have invited the Saxons into Britain to help him against the Picts and Scots, but the Saxons made use of this invitation in order to become masters of the whole of South Britain; and to carry out this work of conquest they obtained the assistance of reinforcements, of which the Danes constituted an important part. In Wales itself a strong resistance was made, and many of the populations of South Britain found shelter there, assisting the Welsh to maintain themselves against all intruders. The nature of the country, with its mountain ranges and its easily-defended passes, enabled them to hold the Welsh territory against hostile invasion.

The British Invasion of Wales. Thus, from about the year 450 A.D., the Welsh were able to keep themselves in something like isolation, until Henry II. invaded the country in 1157 and put a great part of South Wales under the dominion of Britain. The long interval of isolation enabled the Welsh to develop their national characteristics, and to cultivate a literature and a music entirely their own. During that long interval the history of the country resolves itself mainly into struggles between the various princes or chiefs, who claimed dominion over some part of the land, and each of whom was almost always trying to extend his dominion at the expense of some neighbour's territory. There were also frequent struggles going on between Welsh chiefs and the rulers of border states on the English side. The border lines between England and Wales were but indistinctly marked, and gave rise to a variety of disputes ending in war.

Christianity found early recognition in Wales. The Welsh have been always regarded as a people who from almost the earliest Christian days were ever permeated by the religious principle, although divided on many other questions.

Union of England and Wales. The peculiarity of Wales's geographical situation made it all but impossible for her long to retain a position of actual independence. She was made up, for the most part, of races having no affinity with the early ancestry of the British people. The same has to be said of the Irish and the Scots; but Ireland was, at all events, a separate island, and the border-line of Scotland was much more distinctively marked in its position and its geographical construction than that which divided Wales from England. The early history of Wales in its struggles with England is therefore difficult to trace with precision.

In 1282, King Edward I. subdued the whole of Wales, and the death of Llewellyn, the last Welsh sovereign, brought the independence of Wales as a separate realm to an end. When all hope of further resistance on the part of the Welsh people had been abandoned by them, an agreement, known as the Statute of Wales, was devised by the conquerors and had to be accepted by the conquered. This statute proclaimed that "Divine Providence has now removed all obstacles, and transferred wholly and entirely to the King's dominions the land of Wales and its inhabitants, heretofore subject unto him in feudal right." The long struggle between England and Wales was marked by many brave and desperate efforts at resistance on the part of the Welsh, and a whole literature of picturesque and romantic incident has grown out of the events of those days. The Welsh people appear through all the vicissitudes of their history, and even long after the rule of England had been established beyond dispute, to have maintained their national character and the resolute independence of their national ways.

The First Prince of Wales. The son of Edward, who was born at Carnarvon Castle in 1284, was the first of the Royal English stock to whom was given the title of Prince of Wales.

With that event it may fairly be said that the history of Wales as an independent State came to an end. This does not mean that the nationality of Wales, any more than the nationality of Ireland or Scotland, became absorbed into that of England, or even that there were not many subsequent efforts to reassert the separate state nationality of each of these three countries; but only that there came a time when, for the historian, Ireland, Scotland, and Wales become parts of the kingdom of England, and that time was marked for Wales by the event which we have just recorded. Mr. Green, in his "Short History," tells us that "from the earliest moment of his reign Edward I. definitely abandoned all dreams of recovering the foreign dominions of his race, to concentrate himself on the consolidation and good government of Britain herself." Mr. Green goes on to say that "with the reign of Edward begins modern England, the England in which we live," and he adds that "it is not that any chasm separates our history before it from our history after it, as the chasm of the Revolution divides the history of France." But Mr. Green shows that the development of the four nationalities makes from that time, in literature as well as in political government, the movement of one great State.

The Isle of Man. Something has to be said in this course about the islands which, like Ireland, have been for centuries regarded as parts of the English Kingdom. The Isle of Man, of which there is no authentic history until about the sixth century, was, from that time, ruled by Welsh kings. Near the end of the ninth century it was invaded and annexed by the Norwegians, led by Harold Haarfager. The Norwegians, as we have seen, were ever in quest of new realms to conquer. Man was ruled by Scandinavian kings until 1266, when Magnus, King of Norway, ceded to Alexander III. of Scotland the possession of this much tried little island which seemed to have the fatal gift of ever attracting new invaders. On the death of Alexander the inhabitants of Man—probably feeling a desire to have their island occupied, if it must be occupied by strangers, at least by strangers who were nearer to them in position and in ways than Norwegians or even Scots—invited King Edward I. of England to take possession of it in 1290. Under some such conditions the Isle of Man remained for a long time, being treated as if it were one of their own under the dominion of the over-ruling Monarch. The island passed into the ownership of the House of Stanley in 1406, when it was granted to that house in perpetuity. They were called Kings of Man until 1651, when the title was changed to Lord. The Isle of Man was held at times by other great houses under this singular method of proprietorship until at last the British Parliament found it more becoming and convenient to buy out the existing owner of the land, and to make the Isle of Man a part of the British Kingdom. This was done in 1765.

The history of the island contains many interesting chapters. In 1651 the Countess of Derby of that day held the island for a time against the whole strength of the Parliament forces. The first Bishopric of Man is believed to have been founded at a very early period in the spread of Christianity, and there are legends which maintain that St. Patrick was the founder of the See. The Isle of Man has an independent legislative body of its own called the Tynwald. It is composed of two Chambers, one made up of the Governor and the Council, and the other known as the House of Keys, whose acts receive the Royal assent. In many chapters of its history the Isle of Man is as picturesque as in its natural formation, and it has attracted much notice in romantic literature.

The Small Islands. The Channel Islands—Jersey, Guernsey, Alderney, and Sark—were invaded and occupied by the Romans and were thus held until nearly 400 years after the birth of Christ. Rollo, a leader of the northmen, captured the Channel Islands and afterwards constituted them a part of the Duchy of Normandy, a possession which he had obtained from the King of France ; but they were made part of England's kingdom by Rollo's successor, William the Conqueror. Alderney and the other Channel Islands were acquired for England by William the Conqueror at the same time—1066. The Hebrides, the western islands of Scotland, find frequent mention among early Roman writers, and were known to Pliny as the Hebudes. These islands were occupied for a long time by the Norwegians, but were yielded to Scotland in 1264, and formally annexed to the Scottish Crown by James V. in 1540. The reading world of modern days probably owes its chief interest in these northern islands to James Boswell's "Journal of a Tour to the Hebrides with Dr. Johnson," published in 1785, devoured at that time by the greedy admirers of everything that came from or had association with Samuel Johnson, and even still holding a place on the shelves of most of our libraries.

The Isle of Wight. The Isle of Wight has undergone probably more conquests and re-conquests than any other of those islands whose history we have just been summarising. It was invaded by the Romans under Vespasian, in the reign of Claudius, and was called by the Romans Vecta, or Victis. Then, when the strength of Rome was beginning to decline, the Saxons took possession of it, somewhere about 530 A.D. The Saxons held it in their keeping for nearly two centuries and a half, and it afterwards came into the possession of the Danes, who occupied it for a considerable time, then left it, but after a long interval made themselves masters once again and ruled it for another long period. The French took a fancy for it and made it their own in 1377, and, indeed, made several subsequent attempts to regain it; but after the Norman conquest it was brought under the dominion of the English Crown. Henry VI. assigned the rule of the island to an English Peer, whom he actually crowned King of the Isle of Wight, after the fashion of those days for the creation of minor sovereigns under the over-ruling monarch. Charles I. was a prisoner in Carisbrook Castle for some months before his execution. The island has many interesting remains of the past which are yet to be seen there. Near to Carisbrook Castle there still are the remains of a Roman villa, while the foundations of a much larger Roman building have quite lately been discovered, the pavements of which retain ample evidences of that Roman architectural art which prevailed in the classic days. The castle was strengthened in all its defensive works at the time of the Spanish Armada, and it is, indeed, one of the most interesting historical buildings of the distant past.

From this rapid survey of the story of our islands it will be seen what an intermingling of various races has gone to make up the populations which now form the centre of the British Empire.

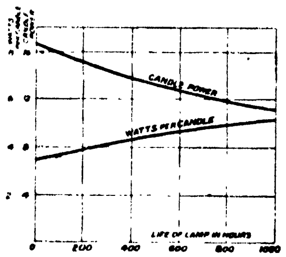
GLOW-LAMPS

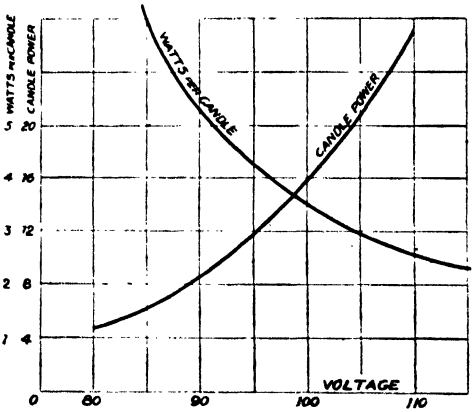
Incandescence by the Electric Current. Manufacture of Glow-lamps. How the Vacuum is produced. Efficiency and Candle-Power. Use of Shades

By Professor SILVANUS P. THOMPSON

IT was the introduction of the commercial incandescent lamp, in 1880–1881, that first called for the supply of electricity on a large scale from central stations. Years before, electricians had known that current passing through a thin wire would heat it, and that under certain conditions it could be made to glow, but the difficulty had been to find a substance which could be kept at a glowing temperature for great lengths of time without melting or becoming disrupted. Most of the metals were, of course, out of the question, because they melt soon after they reach the temperature at which glowing occurs, and the only metal which was ever used to any extent was platinum ; but this was unsatisfactory, as with variations in voltage above the normal the melting temperature was too easily reached. The substance to which inventors then turned their attention was carbon, this having the highest melting-point known. The difficulties to be overcome were, first, to obtain it in the form of a fine wire or filament, and then to seal it into a globe from which the air had been exhausted, for carbon even at a red heat rapidly combines with the oxygen of the air to form the well-known carbonic acid gas. Early in 1879, Swan exhibited a vacuum lamp having within it a carbon wire only 1 millimetre thick. Within a few months this was superseded by lamps having thinner filaments made from thread or paper carbonised. To perfect the filament, many forms, including parchmentised cotton thread (Swan) and bamboo fibre (Edison), were tried ; but at the present time all makers use practically the process briefly described in the following paragraph.



182. AGEING OF LAMPS

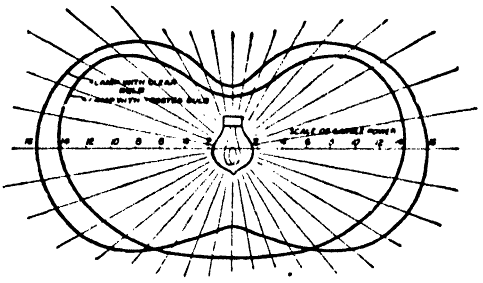


183. EFFICIENCY AT VARIOUS VOLTAGES

The Present-day Filament. Best bleached cotton-wool is dissolved in a warm solution of zinc chloride in water. The mass which results has the appearance of thick treacle, and must be freed from air bubbles and uncombined water by being placed in a vacuum. It is then squirted under pressure through a glass nozzle, and passes into a mixture of methylated alcohol and hydrochloric acid, whch removes all the water from the jelly-like thread. This thread contains the carbon which is going to form the incandescent filament, but it is at present in a state combined chemically with hydrogen and oxygen, and intimately mixed physically with zinc chloride. It is, in fact, a thread of celluloid. The next process is to wind this flexible thread upon blocks to give to the loops the shape which they will afterwards have in the lamp. The blocks are then packed tightly in boxes with charcoal dust, and the boxes containing them are subjected to a gradual and prolonged heating up to 2,000° C., during which the celluloid is transformed into a shiny and extremely flexible black filament, which is almost as hard as diamond.

Flashing the Filament. The preparation of the filament is, however, not yet complete. We pass over the details of gauging and cutting, and reach the stage when it is almost ready to be inserted in the bulb. In order to make a final adjustment of the resistance of the filament, and also to thicken up any places of reduced diameter, it is mounted in a stand, a bell jar is lowered over it, and the air is exhausted prior to the introduction of a volume of a carbonaceous vapour such as that of benzine. On the filament being heated by passing current through, the vapour deposits some of its carbon upon the filament. If any part of the filament be smaller in diameter than the rest, this part, on the passage of the current, will be hotter than the other parts and so will receive a greater deposit of carbon. The filament is then ready to be sealed into the bulb. Some makers do not now use the flashing process, but simply standardise the filaments by careful selection.

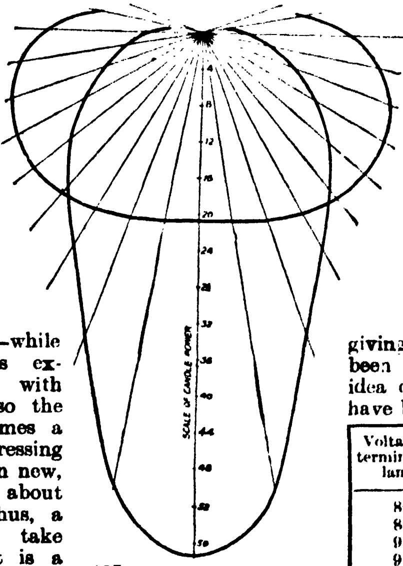
Exhausting the Lamp Bulbs. Ordinary air-pumps never exhaust the air completely from a bulb, but leave a residuum. It was the invention of the mercurial air-pump by Sprengel, and its improvement by Crookes and by Stern, which enabled Swan to produce the first well-exhausted glow-lamps. For many years all glow-lamps were pumped out by mercurial air-pumps, because these alone gave results sufficiently near to a perfect vacuum. But about six years ago it was found possible to employ improved mechanical air-pumps, the last trace of oxygen in the bulb being subsequently removed chemically by the introduction into the lamp of a minute quantity of phosphorus.



184. DISTRIBUTION OF LIGHT FROM INCANDESCENT LAMP

Physics of the Incandescent Lamp. Considered from the point of view of energy, the incandescent lamp is a piece of apparatus for transforming electrical energy into light energy. As is usual in any transformations of energy, a certain amount goes to waste as heat. In the present case the energy which is wasted is many times that which is usefully applied, and consequently we may hope for very great improvements in the economical manufacture of light from electricity. By immersing a lamp in water and measuring the heat given to the water, it was found that from 4 to 5 per cent. of the electrical energy only had been turned into light, the rest being given out as heat.

The *efficiency* of a lamp is not, however, expressed in this way, but by the number of watts required to produce each candle-power of light that the lamp gives out. The energy we give to the lamp per second is measured, of course, by the current multiplied by the volts—*i.e.*, the watts [page 292]—while the amount of light is expressed by comparing it with a standard candle; and so the "watts per candle" becomes a very convenient way of expressing the quality of a lamp. When new, a good lamp should require about 3·5 watts per candle. Thus, a 16-candle power lamp will take about 56 watts, and if it is a 100-volt lamp the current required will be 0·56 ampere.



185. LIGHT DISTRIBUTION FROM SHADES IN 186 AND 187

Voltage, Candle-power, and Efficiency. In the manufacture the filament of a lamp has been so gauged as regards length and diameter that on applying at its terminals the voltage at which it is marked it will take such a current as will cause it to give out the candle-power at which it is rated. The quality of the carbon in the filament determines whether the lamp comes up to the required efficiency under these conditions. It is important to inquire what happens when the voltage applied to the lamp is more than that specified. With an increase of voltage we have a corresponding increase of current. This larger current will raise the filament to a higher temperature, and as carbon, unlike all the metals, has a negative temperature coefficient [page 671], the resistance of the lamp is decreased and more current flows, tending, therefore, to raise the temperature still higher. The rise in temperature is thus more than proportional to the rise in voltage. If to this we add the fact that incandescent bodies show very much increased amounts of light for slight increases of temperature, we shall readily understand that by a slight rise of voltage we may easily double the amount of light emitted by the incandescent lamp. As a matter of fact, it is found that the candle-power of a lamp is roughly proportional to the *sixth power* of the voltage—*i.e.*, if we increase the voltage at a lamp from 100 to 102 we increase the candle-power from, say, 100 to 100 × 1·02 × 1·02 × 1·02 × 1·02 × 1·02 × 1·02 (= 112·6), and we can double the candle-power by increasing the voltage about 12·2 per cent. As we are getting much more light for this small increase in current it follows that the lamp is working more efficiently. That this is so is seen from the following table, which is compiled from actual tests. A column giving the candle-power has also been added, and to give a better idea of these variations the figures have been plotted in 182.

Voltage at terminals of lamp.	Candle Power.	Watts taken for each candle-power.
80	4·6	—
85	6·3	7·0
90	8·5	5·3
95	11·9	4·24
100	16·0	3·5
105	20·7	2·9
110	27·2	2·5

The Ageing of Incandescent Lamps. The considerations in the preceding paragraph lead up to another point. If the lamps are so much more efficient as regards energy consumption when they are run at a higher voltage than that stamped upon them, why do we not run them at this increased voltage? The reason is that all incandescent lamps, whether gas or electric, deteriorate with use, and this deterioration is the more rapid the higher the temperature at which they are used. The *life*, or the time during which an electric lamp will burn before breaking, when used at normal voltage, may be anything from 1,000 to 2,000 hours. During this time, however, the lamp is slowly losing its power and efficiency, and it may be advisable to discard it long before it would finally break. The deterioration appears to be due mainly to two causes: (1) a decrease in the conducting quality of the carbon, so that its resistance goes up and its surface becomes less powerful in emitting light; and (2) the few millions of molecules of gas still left in the bulb after the exhaustion process, in their violent to-and-fro movements, impinge upon the white-hot carbon, convey particles of it away and deposit them on the surface of the bulb. The decrease in power and efficiency is shown in the following table, from which curves in **183** are plotted. The figures are compiled from experiments carried out on forty-eight 200-volt lamps of various manufactures:

Time of burning in hours.	Candle power at end of time.	Watts per c.p. at end of run.
100	15·9	3·81
200	15·0	3·98
300	14·3	4·13
400	13 7	4·29
500	13·1	4·45
600	12·6	4·60
700	12·2	4·72
800	11·8	4·88
900	11·5	5·00
1000	11·3	5·08

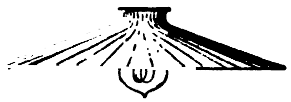
Deterioration of Lamps. Now, with regard to the increased efficiency at higher voltages, because the lamp is being used more violently, we should expect that the deterioration would be more rapid. Such is, indeed, the case, and it is found by experiment that a lamp run at 10 per cent. above its normal voltage runs for only about twelve hours. The following table shows very clearly the marked decrease in life which occurs when lamps are run at voltages which are within the voltage variations allowable in ordinary house supply:

Percentage of Normal Voltage.	Percentage of Normal Life.
100	100
101	88
102	68
103	56
104	45

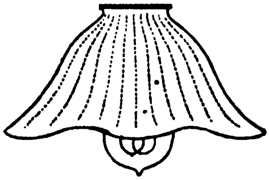
The table demonstrates that it is false economy to over-run lamps, and also shows how important it is to have the voltage kept as constant as possible. In places where energy is cheap—say, 1d., 2d., or 3d. per unit—it may be worth while to over-run lamps slightly, because an extra expense in renewals can be more easily allowed. In places where the price is above 3d. per unit, it is generally best to run the lamps at the rated voltage and to throw them away after they have been in use some 400 or 500 hours, because, after this, running expenses will soon amount to the cost of a new lamp.

The Use of Large Lamp-bulbs. To reduce the amount of blackening on the inside of the lamp-bulbs, several manufacturers have recently adopted a type of lamp in which, although the filament is the same size as hitherto, the globe is two or three times the usual size. With this arrangement the molecules do not impinge with either as much force or frequency upon the hot filament, and any deposit of carbon which takes place now is spread over a larger area and is therefore less dense and less resisting to the transmission of the light.

The Candle-power of a Lamp. It is a difficult matter to define what is the candle-power of any source of illumination. A lamp emits light in all directions, and the difficulty of measurement arises from the fact that in some directions more light is being transmitted than in others. Fig. **184** shows diagrammatically the amounts of light emitted in the various directions. This lamp was evidently rated by the maximum amount of light it gave out in one direction, but another way is to estimate the total flux of light in every direction; and the average is spoken of as the "mean spherical candle-power." In street lighting, however, seeing that all light sent upwards is useless, it is more usual to speak of the "mean *hemi*-spherical candle-power," meaning the mean candle-power emitted in all directions below the horizontal. The second curve given in **184** shows the effect of *frosting* the lamp-bulb, This diminishes by about 12 to 15 per cent. the total amount of light, but at the same time diffuses the light so that it is not very glaring in any one direction.



186. SHADE FOR DISTRIBUTING LIGHT



187. SHADE FOR CONCENTRATING LIGHT

Illumination for Various Purposes For the purpose of marshalling the distribution of the light, shades and reflectors are used. For this purpose white opaque materials (better not shiny) are preferable to mirror glass, because, although the loss in transmitting the light is 2 or 3 per cent. more, no deep shadows are thrown, and the lighting is therefore much softer. The shape of the shades and reflectors determines the quality of the illumination, and in **185** we have curves showing the light transmitted in various directions, using the shade shown in **186** and **187** with the same lamp. The first shade is evidently suitable for a distributive illumination, while the second is for concentrating the light, and should not be used for such as drawing-room lighting except if very intense lighting is required, when it can be used in clusters of four or five lamps each.

3. Being the Concluding Part of Our Study in the Prose of this Period—from Carlyle to Stevenson—together with a Bibliographical Summary

By J. A. HAMMERTON

Mrs. Carlyle. Almost as interesting as anything Carlyle wrote was the story of his own married life; in some way, indeed, that has been fruitful of more controversy than any of his boldest assertions in the domain of philosophy. JANE WELSH CARLYLE (b. 1801; d. 1866) was almost as notable a woman as her husband was a man, for her "Letters and Memorials" prove her to have been one of the most accomplished women of her time, a shrewd critic, fit to rank with the great letter-writers who have contributed no inconsiderable proportion of what we call our national literature. Mrs. Alexander Ireland wrote an excellent "Life" of Mrs. Carlyle.

Lord Macaulay. But Carlyle's greatest contemporary as an essayist and historian was THOMAS BABINGTON MACAULAY (b. 1800; d. 1859). Unlike Carlyle, Macaulay did not confine his labours to the desk. He was a public official and a member of Parliament as well as a man of letters. After a careful education, he became famous at the age of twenty-five as the writer of an essay on Milton in the "Edinburgh Review." In this review all his best known "Essays" appeared, if we except the biographies of Atterbury, Bunyan, Goldsmith, Johnson, and Pitt, which were contributed to the "Encyclopædia Britannica." The "Essays" are rich in applied knowledge, drawn from the exceptionally retentive memory of an omnivorous reader. The judgments they contain, where these are not affected by the author's Whig sympathies, are usually sound. For a parallel to their diversity of subject matter we must go to Landor's "Conversations." But Macaulay was essentially a popular writer, one whose purpose was to think for his readers and to leave nothing to chance. Whole generations may be said to have been nurtured on his writings. His influence will always be considerable both as a stylist and as a historian, though he will require to be edited with some care. The "Essays" on Warren Hastings and John Hampden, for example, are both based on inaccurate data. His great quality is clearness of diction, which he shares with Cobbett; but his use of a succession of short sentences, while flattering to the eye, is not invariably acceptable to the ear. He is apt to overburden his theme with detail. His use of antitheses is responsible for much deplorably ineffective imitation. He remains, withal, a brilliant writer; but, being brilliant, is hard. What he gains in glitter he misses in emotion; he does not delve very deeply into the heart of things; but without his aid many men and women of average insight and ability would never have been able to see so far or so well as they have seen. In this connection the educative value of Macaulay's writings cannot easily be exaggerated; it may be more easily satirised. In the realm of prose his relation to Carlyle is that of Tennyson to Browning in the realm of poetry. It is curious to notice that, in judging Scott, both Carlyle and Macaulay erred, if at all, on the side of severity; but it is useful to remember that neither of them had the "Journal" before him. Macaulay has been infinitely happier in his biographer than was Carlyle; the fine tribute of his nephew, Sir George Otto Trevelyan, to his memory reveals to us a family affection, for any sign of which we might search the "Essays" in vain.

Specimen of Macaulay's Style. We give as a sample of Macaulay's style a famous passage from the "Essay" on Von Ranke (1840):

"The Catholic Church is still sending forth to the farthest ends of the world missionaries as zealous as those who landed in Kent with Augustin, and still confronting hostile kings with the same spirit with which she confronted Attila. The number of her children is greater than in any former age. Her acquisitions in the New World have more than compensated for what she has lost in the Old. Her spiritual ascendancy extends over the vast countries which lie between the plains of the Missouri and Cape Horn, countries which, a century hence, may not improbably contain a population as large as that which now inhabits Europe. . . . She saw the commencement of all the governments and of all the ecclesiastical establishments that now exist in the world; and we feel no assurance that she is not destined to see the end of them all. She was great and respected before the Saxon had set foot on Britain, before the Frank had passed the Rhine, when Grecian eloquence still flourished in Antioch, when idols were still worshipped in the temple of Mecca. And she may still exist in undiminished vigour when some traveller from New Zealand shall, in the midst of a vast solitude, take his stand on a broken arch of London Bridge to sketch the ruins of St. Paul's."

Touching the study of Macaulay, it may be well to refer the student to our remarks on page 107, where, it will be remembered, we agreed upon a plan of study for different authors, making special mention of Macaulay.

Carlyle's Contemporaries. JOHN STERLING (b. 1806; d. 1844) was greater as a literary influence than as a writer. But he was a valued contributor to several reviews; his "Essays and Tales" were edited by his former tutor, J. C. Hare, and he was for a time proprietor and editor of the "Athenæum," and founder of that once famous literary circle, the Sterling Club. RICHARD CHENEVIX TRENCH

(b. 1807; d. 1886) was an indefatigable philologist whose "Study of Words" and other kindred books have proved worthy of bringing up to date. William Spalding (b. 1809; d. 1859) was a contributor of Shakespearean articles to the "Edinburgh," and wrote a small "History of English Literature." Edward FitzGerald, a member of the Sterling circle, is, as a prose writer, best represented by his "Euphranor: A Dialogue on Youth," and his wonderful letters. A now all but forgotten worthy, Robert Aris Willmott (b. 1809; d. 1863) did not a little by his biography of Jeremy Taylor to promote a study of that writer, and by a charming little work on the "Pleasures, Objects, and Advantages of Literature" to win a well-merited reputation for quiet and simple scholarship. John Brown (b. 1810; d. 1882), the author of some delightful essays entitled "Horæ Subsecivæ" (Leisure Hours), will always have a place by the side of Charles Lamb. He is easily among the masters of English prose, and his little sheaf of writings is one of the most precious in our harvest of Literature. John Forster (b. 1812; d. 1876) wrote many admirable essays in history and biography. His "Life of Dickens" remains the most popular of his works. Sir Arthur Helps (b. 1813; d. 1875) wrote a series of essays and dialogues entitled "Friends in Council," which have long lost favour. He edited the speeches and addresses of the Prince Consort and Queen Victoria's "Leaves from a Journal of Our Life in the Highlands." To Richard William Church (b. 1815; d. 1890) we owe a standard criticism of Dante and able studies of Spencer and Bacon in the "English Men of Letters." Mark Pattison (b. 1813; d. 1884), another contributor (of the volume on Milton) to this series, wrote a "Life of Isaac Casaubon," a well-known classical scholar who lived in the sixteenth century. Compared with his scholarship, Pattison's output was singularly limited; but his life-story is a fascinating if sad one. He is mercilessly caricatured as Mr. Casaubon in "George Eliot's" "Middlemarch." Sir Charles Gavan Duffy (b. 1816; d. 1903) wrote a charming work on "The Ballad Poetry of Ireland." George Henry Lewes (b. 1817; d. 1878) founded and edited the "Fortnightly Review," and did much to popularise philosophy and science.

Froude and Others. The name of James Anthony Froude (b. 1818; d. 1894) is the centre of a perfect whirlwind of controversy. As a partisan he excelled Macaulay. His contentious character colours all he wrote, but his "Nemesis of Faith," "Oceana," "Short Studies on Great Subjects," and his "Lectures" possess a positive if all but indefinable fascination for most readers. He wrote with a sincerity that was almost Carlylean, and his thought frequently soars to heights of undeniable eloquence. George Brimley (b. 1819; d. 1857) was a critic whose anonymous contributions to "Fraser's" and the "Spectator" thoroughly merited their republication in collected form. His studies of Tennyson, Wordsworth, Patmore, Carlyle, Thackeray, Lytton, Dickens, Kingsley, Wilson, and Comte justify his place in literary history by the side of such writers as Richard Holt Hutton (b. 1826; d. 1897), Walter Bagehot (b. 1826; d. 1877), James Hannay (b. 1827; d. 1873), Henry Hill Lancaster (b. 1829; d. 1875), Henry Morley (b. 1823; d. 1900), Sir James FitzJames Stephen (b. 1829; d. 1894), Leslie Stephen (b. 1832; d. 1904), William Minto (b. 1845; d. 1893), James Thomson, "B.V." (b. 1834; d. 1882), William Ernest Henley (b. 1849; d. 1903), and others.

The Influence of Ruskin. John Ruskin (b. 1819; d. 1900) proved a great social force as well as a great critic. Perhaps his paramount service in criticism was his defence of Turner. He imparted an incalculable impetus to the raising of the standard of labour; whatever nature of labour it may be, it can hardly be regarded without some respect by anyone who has come under the influence of Ruskin's teaching. Like Carlyle, and, in a lesser degree, like Froude, Ruskin gloried in the power of imparting and inspiring enthusiasm. He sought after the truth with all the ardour of Carlyle, and the student of his works will witness with mingled feelings how, time after time, he was compelled by his own discoveries to relinquish positions he once thought to be unassailable. He was the embodiment of the spirit of reverence and a high priest of the temple of beauty. He has opened our eyes to the infinite variety and charm of external nature, and even the clouds have a different meaning to us since Ruskin wrote about them. His style glows with rich colour and is full of musical sweetness. It is impregnated with the influence of Bible study, an influence which, however, can be realised only by those whose knowledge of the Bible corresponds in some measure to his own.

What Arnold Taught Us. Matthew Arnold (b. 1822; d. 1888), whose work as a poet has been discussed in these pages, combined social with literary criticism. He foretold the fall of the aristocracy and distrusted the middle-classes, but much that has been written and said concerning his "contempt for unintellectual people" is unjustified, and caused him no small amount of disquiet, as his "Letters"—especially the epistle written to his mother in 1868—testify. As a writer, he had much in common with Sainte-Beuve, perhaps the greatest literary critic of the nineteenth century, his standpoint in regard to art and letters being in many respects more French than English. First and foremost he was a scholar, and valued scholarship highly. His "Essays in Criticism," "Culture and Anarchy," "Literature and Dogma," and an earlier work, "On Translating Homer," are his most widely-read books; but there is no complete edition of his prose writings, and no definite biography has been written of him. Mr. G. W. E. Russell, in his very able but unsatisfying monograph, sums up the indebtedness of his friends and followers to Matthew Arnold in these words: "We who were happy enough to fall under his personal influence can never overstate what we owe to his genius and his sympathy. He showed us the highest ideal of character and conduct. He taught us the science of good citizenship. He so interpreted Nature that we knew her as we had never known her before. He was our fascinating and unfailing guide in the tangled paradise of literature. And while for all this we bless his memory, we claim for him the praise of having enlarged the boundaries of the Christian Kingdom by making the lives of men sweeter, brighter, and more humane."

Walter Pater and Others. Eminent among the other critics who lent distinction to English letters in the latter part of the nineteenth century was WALTER HORATIO PATER (b. 1839; d. 1894), whose exclusiveness was akin to that which so long kept Matthew Arnold aloof from the average reader, and whose "Sketches in the History of the Renaissance," "Imaginary Portraits," and "Appreciations" are marked by an exotic beauty of style, refinement of taste, breadth of culture, and keenness of insight. Into the point of view of Walter Pater it is not here necessary to enter, but this must come into consideration where the permanent value of his work is considered. A similar remark is called for in regard to the writings of another and a less "precious" hedonist, JOHN ADDINGTON SYMONDS (b. 1840; d. 1893), who also helped to bring the bright side of the Renaissance, as well as that of Elizabethan England, before English readers. PHILIP GILBERT HAMERTON (b. 1834; d. 1894) wrote a series of letters on "The Intellectual Life" which literary aspirants should not neglect. Young people especially should read "The Ideal Life," by HENRY DRUMMOND (b. 1851; d. 1897), author of "Natural Law in the Spiritual World," whose "Life," by George Adam Smith, is one of the finest of modern biographies.

Another critic of varied talent and remarkable industry was WILLIAM SHARP (b. 1856; d. 1906), and there is literary charm in the essays of RICHARD JEFFERIES (b. 1848; d. 1887), while a fine quality marks the essays of ALFRED AINGER (b. 1837; d. 1904). The life work of RICHARD GARNETT (b. 1835; d. 1906), biographer and literary historian, should be studied as exemplifying the possibilities of self-help and the value of adopting a wide, as against a narrow and "specialist," interest in literature—a point we have already found occasion to emphasise.

The Essays of "R. L. S." ROBERT LOUIS BALFOUR STEVENSON (b. 1850; d. 1894) has been described as "the happiest master of vagabond discourse in the whole of the nineteenth century." He travelled directly for his health's sake; the indirect benefit of his travels to English literature it is difficult to over-estimate. He began as an essayist, and his chief prose works, apart from fiction, are "An Inland Voyage," "Travels with a Donkey in the Cevennes," "Virginibus Puerisque," "Familiar Studies of Men and Books," "Memories and Portraits," and "Across the Plains." He won fame first as a writer of romance, and then, turning to the hitherto almost neglected prose essays, the public found in them the most intimate and delightful self-revelations of a winning personality. Stevenson's style is the outcome of infinite labour; it is not a style that could be copied with profit, but the young writer with aspirations should read, mark, learn, and inwardly digest all the books we have just named. "In an age of journalism," says Professor Raleigh, "of barren repetition and fruitless expatiation, it is high praise to give even of a great prose writer to say of him that he never proses. This praise is due to Stevenson; his chisel, which rang in the workshop of many masters, was always wielded under the direction of a marvellously quick eye, by a hand that gathered strength and confidence every year. He has left no slovenly work, none that has not an inimitable distinction, and the charm of expression that belongs only to a rare spirit. If the question be raised of his eventual place in the great hierarchy of English writers, it is enough to say that the tribunal that shall try his claims is not yet in session; when the time comes he will be summoned to the bar, not with the array of contemporaries whose names a foolish public linked to his, but with the chief prose writers of the century, few of whom can face the trial with less to extenuate and less to conceal."

We have now noted most of the important prose-writers of the nineteenth century, excluding those who are still alive; but there remain a good many names which call at least for mention, and without endeavouring to compile a complete list of these, we shall indicate as many as possible in the bibliographical summary with which we bring this section of our study to a close. It will be worth our while to reserve for separate consideration those writers who, though essentially of the nineteenth century, are still living. Therefore, in our next study we shall pass in review the representative writers of prose, other than that of fiction, from Masson to Chesterton.

Biography and History. The works of some of the chief biographers and historians of the nineteenth century have been referred to already. In the field of biography the following books are generally admitted to be of permanent value: Southey's "Nelson"; Lockhart's "Scott"; Lewes's "Goethe"; Carlyle's "Sterling"; Froude's "Carlyle"; Stanley's "Arnold"; Forster's "Dickens"; Milman's "Gibbon"; Mrs. Gaskell's "Charlotte Bronte"; Masson's "Milton"; Spedding's "Bacon"; Sidney Lee's "Shakespeare"; Gifford's "Ben Jonson"; Cross's "George Eliot"; Dowden's "Shelley"; Martin's "Prince Consort"; John Morley's "Voltaire," "Rousseau," and "Gladstone"; and Lord Tennyson's "Life" of his father.

History bulks largely in the period under review. The chief works on English history are Hallam's "Constitutional History of England"; Lingard's "History of England to 1688"; Macaulay's "History of England, from the Accession of James II."; Carlyle's "Cromwell's Letters and Speeches"; Froude's "From the Fall of Wolsey to the Defeat of the

Armada"; Green's "Short History" (the best of its kind); Gardiner's "History of England, 1603–1642," "History of the Great Civil War," "History of the Commonwealth and Protectorate," and "Oliver Cromwell"; Freeman's "History of the Norman Conquest," "Growth of the English Constitution," and "The Reign of William Rufus"; Stubbs's "Constitutional History of England"; Sharon Turner's "History of the Anglo-Saxons"; Seeley's "The Expansion of England"; Buckle's unfinished "History of Civilisation"; Lecky's "History of England in the Eighteenth Century," and other works on European history; Seebohm's "The Oxford Reformers of 1498," "Era of the Protestant Revolution," "The English Village Community," and "Tribal System in Wales"; Creighton's "Simon de Montfort," "History of the Papacy during the Reformation Period," "Queen Elizabeth," and a charming little manual on "The Age of Elizabeth"; Palgrave's "Rise and Progress of the English Commonwealth"; Firth's several books on the Commonwealth; Brewer's "Henry VIII."; and May's "Constitutional History of England, 1760-1863."

In addition must be noted Mill's "History of British India"; Maine's "Village Communities," and "Popular Government"; Tytler's "History of Scotland"; Burton's "History of Scotland"; Coxe's "House of Austria"; Grant Duff's "History of the Mahrattas"; Elphinstone's "History of India," and "Rise of the British Power in the East"; Kaye's "Histories of the Afghan and Sepoy Wars"; Kinglake's "Crimea"; Mitford's, Thirlwall's, Grote's, and Finlay's histories of Greece; Thomas Arnold's "History of Rome"; Alison's "History of Europe"; Merivale's "History of the Romans under the Empire"; Milman's "History of Latin Christianity"; William Napier's "History of the Peninsular War"; and Agnes Strickland's "Lives" of the Queens of England and Scotland.

Theology and Philosophy. Students of philosophy and theology are recommended to refer to the following names in any good biographical dictionary: Jeremy Bentham, Sir William Hamilton, Henry Mansel, Richard Whately, William Whewell, David Ricardo, J. R. McCulloch, John Stuart Mill, Richard Owen, Charles Darwin, Herbert Spencer, Thomas Henry Huxley, W. A. Butler, Thomas Hill Green, G. H. Lewes, Sir James Mackintosh, Thomas Malthus, John Keble, Edward Bouverie Pusey, Richard William Church, John Henry Newman (whose style is especially important to students of the language), W. E. Gladstone, Arthur Penrhyn Stanley, Thomas Chalmers, John William Burgon, Richard Hurrell Froude, Edward Irving, Henry Parry Liddon, Joseph Lightfoot, Frederick Denison Maurice, James Mozley, James Craigie Robertson, Frederick William Robertson, Richard Chenevix Trench, John Tulloch, Christopher Wordsworth, William Wilberforce, Charles Haddon Spurgeon, R. W. Dale, and James Martineau.

Travel and Science. The records of travel and exploration are brightened by such names as those of Austen Layard, Samuel Baker, David Livingstone, John Pinkerton, Charles Waterton, George Borrow, Richard Burton, and Edward Lane. Some mention must also be made of the scientific studies of Max Müller, Charles Lyell, John Tyndall, and Humphry Davy. The educational writings of four women—Harriet Martineau, Hannah More, A. L. Barbauld, and Charlotte Yonge—may be cited as witnesses to the rise and progress of "woman's emancipation," which was so striking a feature of the nineteenth century.

Books to Study. There is no satisfactory history of our nineteenth century prose. The nearest approach to one is found in Professor Saintsbury's work (Macmillan, 7s. 6d.). The final volume of Sir Henry Craik's "Selections" (Macmillan, 8s. 6d.) is an invaluable guide. The "Maclise Portrait Gallery," by William Bates (Chatto & Windus, 3s. 6d.), is a mine of useful information concerning the men and women of letters who lived during the earlier half of the century. Messrs. Chatto and Windus also issue M. Taine's "History of English Literature," in four volumes, at 2s. net a volume. Professor Herford has edited for Messrs. Blackie, a series of volumes called "The Warwick Library." Of these, "English Historians," by Professor Grant; "English Essays," by J. H. Lobban; and "English Literary Criticism," by Professor Vaughan (2s. 6d. per vol.), contain much that is commendable. The following volumes in the "English Men of Letters" series are also recommended: "Carlyle," by Professor Nichol; "De Quincey," by Professor Masson; "Charles Lamb," by Canon Ainger; "Landor," by Sidney Colvin; "Matthew Arnold," by H. W. Paul; "Macaulay," by J. L. Morison; "Hazlitt," by Augustine Birrell; "Ruskin," by Frederic Harrison; "Edward FitzGerald" and "Walter Pater," by A. C. Benson. Matthew Arnold is also the theme of useful monographs by G. W. E. Russell (Hodder & Stoughton, 3s. 6d.); W. Harbutt Dawson (Putnam's, 6s.); and Professor Saintsbury (Blackwood, 2s. 6d.). For Messrs. Blackwood's "Modern English Writers," Mr. L. Cope Cornford has written a Life of R. L. Stevenson; Lives of Ruskin and Huxley have been written by Mrs. Alice Meynell and Mr. Edward Clodd respectively. Dr. Barry's Life of "Newman" (Hodder & Stoughton, 3s. 6d.) is excellent. Messrs. Ward, Lock have published shilling editions of Cobbett's two grammars, and this virile writer's "Advice to Young Men" has been republished by Messrs. Routledge, also at 1s. Inexpensive reissues of Carlyle's works are published by Messrs. Chapman & Hall; while Messrs. Longmans have rendered similar service by the publication of popular editions of the works of Macaulay (together with the "Life," by Sir G. O. Trevelyan) and Froude. Mr. George Allen is producing Ruskin in inexpensive form, and much of R. L. Stevenson has been added to Messrs Chatto & Windus's "St. Martin's Library."

DISEASES OF LIVESTOCK

Symptoms and Method of Treatment of the Chief Diseases of Horses, Cattle, Sheep, and Pigs. A Medicine Chest. Insect Parasites

By Professor JAMES LONG

DISEASES OF HORSES

The temperature of the body frequently proves a guide in sickness. The stockowner should, therefore, obtain a clinical thermometer and learn how to use it. The temperature of the horse is from 100° to 101° F., a rise to 103° denoting a feverish condition, and from 105° to 106° a high fever. The bulb of the thermometer is very carefully introduced into the rectum, and there maintained from three to four minutes in order to obtain an accurate reading. The pulse, which is usually taken under the side of the jaw, where the artery will be felt, beats from 36 to 45 times per minute in health, but the horse must be perfectly quiet. A beat of over 60 denotes fever. The pulse is rapid and small in such complaints as inflammation of the bowels, and weak in influenza; but inasmuch as its volume, rhythm, and character are all important, professional help should be obtained in cases of grave suspicion. Under normal conditions, the horse when standing quiet breathes 12 times in a minute.

The horseowner should carefully remember the fact that there are certain contagious diseases, anthrax, glanders, farcy, and rabies, which are scheduled, and which must be notified to the police or such authorities appointed for the purpose, even where the complaint is only suspected. All being dangerous to man, this notification, accompanied by absolute isolation of the animal, is all the more important.

Colic and Gripes. These much too common complaints are frequently caused by improper feeding or sudden change of food; by impaction; by the taking of too much green food, or by drinking a quantity of cold water when overheated. The animal perspires freely, and rolls on the ground in pain, which may be spasmodic. An injection of warm water often affords relief, or a dose of from 5 to 10 drams of aloes where spasm exists. If there is flatulence, linseed oil or ammonia is useful, together with massage. It is important to ascertain that the case is not one of inflammation, in which the pain is continuous. Gripes are often removed by a draught composed of chlorodyne, hyposulphite of soda, and bicarbonate of potash, the dose being arranged by an experienced chemist, who should be acquainted with the age and condition of the animal.

Enteritis, or Inflammation of the Bowels. This very dangerous disease, from which animals seldom recover, somewhat resembles colic, but the temperature is high, the body cold, the pulse fine and hard, and the belly tender. Hot fomentations are useful, but there is practically no remedy, although in all cases the best skill should be employed.

Gastritis, or Inflammation of the Stomach. This disease closely resembles that just referred to, and is almost equally dangerous. Amateur physicing should be avoided.

Diarrhœa. This is more common in young than in older animals, and may be attributed to chill, sudden change of food, improper food, acidity, or worms. The cause should first be ascertained, and the remedy applied in accordance with it. Foals with their dams may receive a dose of castor oil and laudanum, while acidity in the milk of the dam may be neutralised by the aid of carbonate of soda. Mixtures of opium powder, catechu and chalk, or of catechu and chlorodyne, may be administered, the dose being arranged by a druggist in accordance with the age and condition of the animal.

Glanders and Farcy. This contagious disease—for glanders and farcy are practically one—must, even on suspicion, be notified to the police, the horse being isolated. It is contagious to man, and is the result of the work of an organism known as *Bacillus malleus*. There is a sticky discharge from the nostrils, usually, however, from one nostril. When the disease is recognised or proved by the injection of the material used for the purpose, and known as mallein, the horse is destroyed. In bad cases there is high fever. Glanders and farcy take different forms, the latter affecting the limbs and skin, one disease running into the other.

Catarrh. This somewhat common complaint is not of a serious character, although it should be promptly handled. It is owing to the sudden changes of the weather, coupled with bad or irregular feeding, and indigestion, and may cause loss of condition and weight. A horse with catarrh should be rested in an airy yet warm and dry stable, and fed on simple food, such as mashes of bran, crushed oats, linseed tea, and cooked roots. Little drink should be given. Terebine and spirits of camphor are useful.

Pink Eye, or Distemper. This is an infectious disease attended with great loss of strength and condition, and accompanied with a thin discharge from the nostrils, cough, and fever. The temperature may rise to 104° or 105° F. A redness of the membrane of the eyelid is usual. There is thirst, constipation, and scanty urine, with a weak pulse. The animal should be stabled, as in the case of catarrh, isolated, well nursed and fed, receiving gruel, eggs and milk, if there is great loss of strength, mashes, linseed tea, and steamed crushed oats. A little spirit may be good to sustain the strength. The temperature should be taken, and if the attack is severe, a veterinarian should be employed, since there are occasionally serious complications, involving pleurisy, bronchitis, or the liver.

Pleurisy. This is practically inflammation of the membrane covering the lungs. There is cough, a thin and wiry pulse, with high temperature. The animal should be clothed and kept warm, and mustard applied over the affected part.

Pneumonia. Although this disease is probably owing to the presence and action of a specific germ, it may be indirectly owing to exposure, overheating, and chill, or even a damp stall. The pulse is tiny and very rapid, and the breathing quick. A case should be treated with great promptitude by a professional man.

Strangles. This chiefly attacks young horses. Its most important symptom is an abscess under the jaw, which is usually blistered or fomented until it breaks, or is ready for the lance. In either case it should be kept clean with antiseptic.

Fistula. This disease appears on the withers, and should be attacked immediately it is noticed, inasmuch as if neglected the bony structure beneath may be implicated and recovery become impossible. The aid of a veterinary surgeon is essential, that the part may be opened and cleansed. The affected horse should not be worked, but allowed freedom for sufficient exercise and pure air. The feeding should be sound but not high, the efforts of the owner being directed to maintenance of good bodily condition, that the animal may throw off the abnormal formation, and build up new tissue.

Worms. The digestive organs of the horse are attacked from time to time by worms [7, page 2627] of parasitic character of several varieties. Some are known to be consumed when grazing, especially on wet land. This is the case with the red parasite known as *Strongylus tetracanthus*, a bloodsucker, the presence of which is followed by diarrhœa, wasting, and often by death. It may be noticed in the manure of the horse, and wherever observed steps should immediately be taken to remove the animal into a dry, light, and well ventilated box which is thoroughly clean, and to feed and nurse him in the best manner possible, milk and eggs, linseed tea, gruel, and mashes being employed. The treatment of horses with worms, however, depends upon the variety of the parasite. Turpentine and oil or santonin are usually employed. Here, again, advice will be found the cheapest help in the end.

Cracked Heel. This is usually accompanied by lameness, and may be caused by a wet stall, or constantly wet feet. Washing the feet should be avoided, the dirt being allowed to dry and then removed with a brush. White vitriol ointment may be employed as for thrush and sore shoulders.

Curb. This is a swelling which appears a little below the hock, and is better recognised in profile. The part may be blistered or fired.

Founder, or Inflammation of the Feet. Founder frequently follows bad feeding, cold or wet. The feet become heated, and the horse is in pain, and prefers to rest. He loses condition, and exhibits great thirst, the pulse being meanwhile strong. The shoes should be removed, and cold bran poultices applied to the feet. The bed of the stall should be covered thickly with short straw or peat moss, and very little exercise given, and that on soft soil. A few draughts or drenches should be obtained to help the animal through, a little green food being given when recovery begins.

Grease. This term is applied to a greasy condition of the skin of one or more limbs, and is sometimes accompanied by a discharge. The affected parts may be powdered with boracic acid and alum, and kept clean and carefully bandaged. The animal should be fed well, green food being supplied ; a ball from the veterinarian will help to bring back condition.

Capped Hocks. This is practically a swelling of a tendon, which is followed by a condition resembling a cap over the point of the hock. It may result from a bruise. The seat of the disease may be in or beneath the tendon. The horse should rest, and the affected part be regularly dressed with a lotion obtained from a druggist skilled in these matters or from a veterinarian. There are two or three firms who provide collections of lotions and medicines for simple diseases at reasonable prices.

Broken Knees. Broken knee is usually the result of a fall. A mere bruise or graze, if kept clean, rapidly heals, but where the joint is opened there is a discharge of fluid (synovial), usually known as joint oil. As this is serious, attention must be given at once, and even then prolonged rest and nursing will be necessary for recovery. Care must be taken to remove any grit or dirt, and the wound should be dressed with a special lotion obtained for the purpose, and then bandaged. Both cleaning and dressing should be frequent, the sponge being soaked in water which has been purified with an antiseptic. An oil of cloves dressing on cottonwool will be found useful.

Mange. This is a contagious, inflammatory condition of the skin caused by the activity of a parasite. The horse rubs himself, and the hair falls off, while condition is lost. He should be isolated in a clean stable, and dressed with sulphur ointment. Neither stable nor brushes employed for the patient should be used until thoroughly disinfected.

Mud Fever. This is really an irritation caused by the presence of dirt allowed to accumulate on the skin, and bad stable management ; an eruption also appears, usually on the legs, with loss of condition. The horse may be fed on bran mashes, crushed scalded oats with a little green food and an odd mangel or carrot or two, with a little first-class hay ; an ounce of linseed oil may be given each night and a few powders obtained from a veterinarian.

Navicular. This is a disease of the navicular bone and its surroundings, usually in the fore feet. The horse goes shaky or limp, and although he may do a little work, he becomes practically unsalable. Help can be given, but no cure effected, by a veterinary operation, after which a short-toed shoe with a leather sole may be provided for the affected foot.

Quittor. This involves a swollen and heated coronet with running sores, often caused by the presence of matter arising from a wound in the sole; the matter is discharged from the suppurating sores instead of below. Whether the wound is caused by a nail or otherwise, the place should be cleaned with an antiseptic dressing and encouraged to discharge below by poulticing. In the presence of quittor, however, the sores must be opened, cleaned, and induced to heal by the promotion of a healthy condition of the affected parts. Rest should be given, and the work performed by a veterinarian.

Ringbone. This disease, usually in the hind legs, may be seen when really large, or detected by the fingers of an expert on or near the pastern joint. It may be caused by a blow followed by inflammation and lameness. Rest and firing by a veterinarian may have good results.

Ringworm. Ringworm is caused by a parasite, the irritation being followed by loss of hair. The patches should be kept clean and dressed with tincture of iodine or an ointment.

Sandcrack. In this case the horny structure of the hoof cracks, and may cause lameness; the extension of the crack must be prevented, and a healthy condition promoted by light exercise, cleanliness of the part, and the drawing of the divided portions together. The horse must rest if in pain.

Sidebone. This is a hardening of the flexible cartilage behind the cannon bone, usually on the fore legs. It diminishes the value of a horse, although he may do good work for years. Rest may be necessary, and sometimes firing, but turning out in suitable weather for some weeks may have excellent results.

Spavin. Serious as this complaint is in the horse used for fast work, farm and cart horses suffering from it are commonly employed and often work as well as when sound. Spavin is the result of inflammation which attacks the bone of the hock, and which is followed by enlargement and lameness. If the enlargement is not noticeable, it may yet be discovered by the touch of a skilled hand. The horse should be rested and professionally treated, and the wisest plan is to turn the animal out to grass if weather permits.

Splint. Splint attacks horses ridden and driven rather than cart or farm horses. It is really a bony deposit on the cannon bone, usually of one of the fore legs, which causes lameness. Both heat and pain are present. The former may be reduced by cold sponging, and the latter by resting. A blister may be found useful, but one should be guided by a professional man.

Thoroughpin. This trouble is a fluid distension or swelling, which is movable, and which appears at the back of a hock. It is sometimes painted with iodine, and sometimes punctured, but needs professional treatment.

DISEASES OF CATTLE

Anthrax, or Black Quarter. This very dangerous disease, known under many names, usually attacks young stock, and is due to the presence of a bacillus, and is extremely fatal. The attack is sudden, the limbs swell, stiffness follows, with loss of appetite, extreme weakness, and a weak and rapid pulse. In severe cases death may follow in a few hours. A veterinarian should be called in at once, and no time lost in efforts to sustain strength and to ameliorate the symptoms. The best plan, however, is to act on the principle of prevention, keeping the stock in good condition, never turning them out into fields where anthrax has occurred, and, on farms where there has been loss from the disease, to insert a seton in the dewlap. In case of attack the animal should be isolated, its bed and manure burnt, and its stall purified, while after death the body should be buried in lime, or, still better, burnt, if this is possible.

Catarrh. This is recognised by a running at the eyes and nose, which may follow chill and exposure. It should be checked before going too far, as it may be succeeded by complications of a most serious character. Protection and good feeding are essential. The animal may receive a dose of Epsom salts, in accordance with its age, well fortified with ginger. In a severe case the feeding should consist of good gruel, warm bran mashes, scalded oats, and good hay-chaff, and, if obtainable, some green food—grass, clover or vetches—given in small quantities at a time. The system needs stimulating and well feeding, while a dry stall, ventilation, and a little exercise should be provided.

Husk, or Hoose. This attacks calves and quite young stock turned out to grass, and more commonly in their first year. It is caused by the presence of a worm, *Strongylus micrurus*, in the trachea, or windpipe. There is cough, followed by weakness, and, in bad cases, by death. Wet land should be avoided at all times. When an outbreak occurs, the stock should be changed to drier soil; indeed, all young animals should be fed on dry pastures, and fed well. It is the ill-fed youngster which usually falls a victim to husk, and here the master's eye exercised daily over his herd is so valuable. A daily dose of turpentine may be administered, or, if the case is obstinate, the veterinarian may be instructed to attempt to destroy the organisms, which sometimes respond to skilled action or to inhalation.

Consumption, or Tuberculosis. This is, perhaps, the most destructive among all diseases of cattle. It has been stated on authority that 40 per cent. of the cattle in the country are affected. If it is suspected, the tuberculin test may be applied by a veterinarian, the rise in temperature, if definite, deciding the question.

No tuberculous beast should be sold or allowed to remain near healthy stock, infection being extremely dangerous. Milk should not be sold from a tuberculous beast, nor calves and swine fed on the milk, unless it has been boiled.

Red Water. This serious complaint is usually recognised by the dark or red colour of the urine and diarrhœa, which is usually followed by constipation. Unless in very severe cases, a pound of Epsom salts may be given as a purge, followed by daily doses of oil and turpentine. The disease is accompanied by great weakness, so that good nursing and rich feeding are essential. The animal should receive milk, gruel, linseed tea, and, if necessary, spirits, but in all cases it is a wise policy to obtain the assistance of a veterinary surgeon. The cause of the disease is not fully known, but it is more common on moorland soils than elsewhere.

Influenza. The symptoms resemble intensified catarrh, with fever and prostration. The disease is contagious. If there is constipation, as is most likely, a pint of linseed oil may be given, a little more, if necessary, followed by enemas if the trouble is continued. The animal should be isolated, and advice obtained in all cases. The feeding may consist of bran mashes, gruel, and a little green food from time to time. Water in which linseed has been boiled may be given as a drink. The body should be kept warm in a well-ventilated stall, and good nursing and rest provided.

Pneumonia. This is recognised by a hard cough, cold ears and feet, hot, rapid breathing, chill, weakness, and refusal to eat. The exciting cause is usually exposure and chill. The patient should be well wrapped up in a dry air-box, and fed on milk, mashes, linseed tea, and a little green food. It is always well to obtain an accurate diagnosis, advice, and medicine from an expert.

Pleuro-pneumonia. This is a contagious disease, which must be reported when recognised. It is frequently fatal, running its course with rapidity. There is thirst, cough, refusal to feed, a hot, dry muzzle, foul-smelling breath, and foul, dry manure, with, in bad cases, wasting, and running mucus from the mouth. The disease is imported. In all suspected cases there should be isolation, disinfection, professional advice, and slaughter on recognition.

Foot and Mouth Disease. This is a contagious and disgusting disease, which must be notified to the police. There is shivering, salivation, weakness, rapid pulse, with inflammation, eruption on the mouth, tongue, oftentimes on the feet, and sometimes on the udder. An aperient should be given, to consist of a pint of linseed oil or ¾ lb. of Epsom salts, the affected places being dressed with a sulphate of zinc lotion. Salicylic acid in ¼-oz. doses, or sulphite of sodium in 3-drachm doses in water may be given twice daily. If the feet are attacked, boracic acid may be dusted over them. An attack may involve a number of animals, which will need constant attention to prevent too great loss of condition, and the spreading of the complaint. There should be isolation and complete disinfection. Patients may be supplied with linseed water as drink, linseed tea, milk, mashes, gruel, cut grass, and any food likely to tempt the failing appetite. The milk of affected cows should not be used for healthy stock.

Abortion, Slinking, or Casting Calf. Abortion is caused by accident, exposure, or contagion, the calves being usually cast in the fifth month. In any case the cows should be isolated, thoroughly disinfected, the fœtus, cleansing, and all matter connected with both buried with lime, or burnt. A cow which has once been affected should not be used for breeding again until nine months have elapsed, or she may be fattened and sold. There is always danger in buying in-calf cows in fairs and markets; hence the importance of some days of isolation before mixing with the herd. After a case of abortion every animal in the herd should be disinfected by sponging the vent with a solution composed of 20 pints of distilled water, 3 oz. of glycerine and alcohol (specific gravity 36), and 2½ drachms of bichloride of mercury (poison). One case of contagious abortion may be followed by others unless great precautions are taken.

Milk Fever, or "Drop." This is a very dangerous complaint, often attacking cows which are in high condition and of particular strains. The animal falls soon after calving, displaying weakness, a dry, hot muzzle, and perhaps relapses into a state of coma. The actual cause is unknown; prevention is the wisest course. Fleshy or suspected cows should be turned out on scanty pastures after drying off, or, if stall-fed, kept on light rations, of which bran mashes form part, linseed water being occasionally used to keep the bowels in order. A pint of salts given twice with intervals shortly before calving is a practice many follow with success. Where the appearance of the cow raises suspicion that she may fall, 10 to 12 drops of tincture of aconite may be given, and continued every six hours or so, if there is no change. Where a case occurs, the animal should be well wrapped up to maintain warmth, the bowels being kept open with linseed oil, salts, or a gruel enema.

Garget. This is a troublesome complaint attended with great risk and loss in value in the cow. The udder is attacked by inflammation, and its internal structure involved, so that the power of yielding milk may be lost. It is usually owing to chill, injury, or bad management. The udder becomes hard, but may be massaged, and the calf used to empty it from time to time. When garget appears, the udder may be poulticed with linseed meal, and medicine obtained from the veterinarian. If an ulcer forms, it should be kept clean with an antiseptic, such as carbolic acid, 1 part to 25 parts of water. Simple *hard udder*, which often occurs after calving, may be reduced by giving ¾ lb. of salts and an ounce of ground ginger in gruel, followed by frequent rubbing, and by allowing the calf to suck oftener.

Hoven. This usually occurs from overeating young, fresh green food in spring, especially where cows break bounds and enter a field of vetches, clover, or some other green crop, when the dew is upon it. The animal is blown with gas, parts of abdomen when tapped resounding like a drum. In bad cases the distension presses on the heart, the circulation is impeded, and death may occur by suffocation. The commonest simple remedy is ¼ lb. of hyposulphate of soda, given in a pint of water, this being repeated in a short time if necessary. If it is perceived that a cow is in danger, the paunch should be pierced with a trocar and canula, which should be kept on every farm, or, failing this, with a penknife, behind the short ribs on the left side. The trocar is removed, and the canula, through which the gas quickly passes, remains in the wound, which should be kept clean, and which with care will quickly heal. After relief the animal must be nursed, first getting an aperient—1 lb. of Epsom salts, with some ground ginger, or a pint of linseed oil—to clear the bowels. Food should be given in small quantities until danger has passed, to include gruel, bran mashes, and linseed water.

Impaction. This is also the result of gorging abundant dry or green food. There is less gas in this case, but action should be taken with linseed oil to purge the system. In bad cases advice must be obtained.

Colic. This trouble is often caused by overfeeding or bad feeding, followed by pain in the bowels, the generation of gas, and swelling. The first remedy is 1 lb. of salts, with 1½ oz. of ginger, ½ oz. of aloes being sometimes added. If necessary, a stimulant must be supplied, and in all cases help obtained. There may be gentle massage with dry mustard. The feeding to follow relief should be chiefly composed of bran mashes. Colic may be caused by chill, or drinking too much very cold water. Where there is little gas evolved, but more pain, a pint of linseed oil may be given, followed by a soothing drink, which should include opium, obtained from a veterinary surgeon.

Inflammation of the Bowels. This disease is accompanied by pain, perspiration, and rapid pulse. It is caused by exposure and chill, and the consumption of quantities of cold water when the animal is heated. Ether and opium are usually given, but, again, the master should leave himself in the hands of a skilled adviser.

Diarrhœa. If the fæces are largely mixed with mucus, great weakness soon follows an attack, but simple looseness, although it should not be ignored, may mean nothing. Bad cases occur from sudden changes of food or of pasture, from the consumption of bad food or water, and from chill. A pint of linseed oil with an ounce of tincture of opium may be given to clear the bowels, after which a binding draught may be administered, if necessary, this consisting of powdered chalk, catechu, and opium, the doses being arranged by a good druggist. In bad cases, which may be described as dysentery, the fæces are mixed with blood; there is great weakness, and inflammation of the organs of digestion. In such there must be prompt action, good nursing, and the best advice. Diarrhœa in calves is caused by acidity, chill, and careless feeding. In ordinary cases 1½ to 2½ oz. of castor oil may be given in accordance with the age and size of the animal, followed by periodical doses of a cordial containing powdered chalk, ginger, opium, and catechu. It is prepared by any good druggist. Many cases of diarrhœa are infectious, hence the importance of supreme cleanliness and isolation.

White Skit, or Scour. This is common among calves taking milk. In ordinary cases the oil and cordial may be given as above, but where the disease is the result of a bacillus, Nocard's system must be adopted. The animal shivers, there is rapid emaciation, and death. The discharge is very thin and a yellowish grey. Practically no treatment succeeds in effecting a cure. The one thing is to prevent its occurrence. The bacillus enters the system through the navel cord; hence, when the cow is about to calve she should be kept in a disinfected box on clean straw. The cord of the calf after birth should be tied with thread 1½ to 2 in. below the navel, and cut an inch below the tie. The cord should then be dressed with a solution composed of 1 gramme of iodine crystals, 2 drachms of iodide of potash, with 500 cubic centimetres of water (1$\frac{1}{10}$ pints), and subsequently coated with a solution of 1 gramme of iodine crystals and 500 cubic centimetres of alcohol. This must be allowed to dry thoroughly, when a layer of 1 per cent. iodine collodium should be painted or coated over it, and well dried before the calf is released. Cows about to calve should be disinfected with a 2 per cent. solution of creolin in water. The hands of the operator and the knife and thread employed should be sterilised or disinfected.

Broken Horns. In bad cases the stump may be removed; in others it may be smeared with the best Archangel tar, bound with tow, and subsequently with a clean cotton bandage.

Cowpox. Pustules appear upon the teats, being usually communicated by the hands of milkers; hence the importance of cleanliness. The affected teats may be bathed with a mixture of ½ oz. of chloride of lime in two quarts of water.

Poisons. The most common vegetable poisons are yew and rhododendron; but whether these have been eaten, or whether the animal has in some way consumed mineral poisons, the services of an expert are essential.

The pulse of a beast is taken at the jaw, 45 beats per minute; while the temperature, which is taken in the anus, is 101° F.

DISEASES OF SHEEP

Anthrax and Foot and Mouth Disease. The remarks on these diseases under the head of Cattle apply also to sheep.

Foot-rot, Scab [1], and Vermin have also been referred to in our general remarks.

Catarrh. This is indicated by a running at the eyes and nostrils, sometimes with the addition of a cough, loss of condition, and refusal to feed. The animal should be isolated, nursed, kept warm, and fed with gruel, to which a drachm of nitre may be added from time to time.

Husk. This is accompanied by cough, weakness, and loss of weight. It should be promptly attended to, the affected animal being removed from the flock, which should be shifted on to a dry pasture and liberally fed. Lambs should not feed on grass over which older sheep have been running. The patient should receive a mixture of turpentine and olive oil, prepared by a druggist, and be fed, a small quantity at a time, on nutritious rations, as crushed oats, with a little finely broken linseed cake, and sweet hay-chaff, and gruel or milk, if necessary. The complaint is caused by the presence of a worm, *Strongylus filaria* [10].

Pneumonia. An attack of this disease is accompanied by fever, loss of condition, thirst, laborious breathing, and refusal to feed. It is caused by exposure and chill, and is dangerous. The strength should be maintained by the aid of spirits, two tablespoonfuls being given in linseed tea, milk, or gruel, with a little ginger added. Expert advice is essential.

Trembles, or Louping Ill. This disease, which affects the nerves, is believed to be due to the presence of a fungoid parasite communicated through the sheep tick. Hence the importance of keeping the wool and skin free from parasites by dipping at least twice yearly. The symptoms are tremor and grinding of the teeth. The disease is very dangerous, and is seldom cured. Where a case occurs the flock should be moved on to a clean, pure pasture, supplied with salt, and liberally fed.

Staggers, or Sturdy. This is easily recognised by a peculiar movement of the head, while the animal turns in a circle. It is due to the presence of a parasite in the brain, *Cœnurus cerebralis*, which is communicated through the tapeworm of the dog. There is no effective cure. The animal had better be killed while the carcase possesses any value. Wet pastures should be avoided; the dogs of the farm kept healthy, and salt supplied to the flock.

Braxy. This is a highly fatal disease, which it is almost useless to treat. The head hangs, the back is rigid, and there is grinding of the teeth. The direct cause is believed to be found in bad feeding, especially on decomposing grass. A palliative is found in a supply of salt to the flock, and good sound pastures. The diseased sheep should be at once isolated, and a purgative in gruel may be tried, or a veterinarian called in, but in all cases slaughter is the most economical course to adopt.

Dysentery. This is recognised by abnormal, fetid droppings, mixed with mucus and blood, with fever, weakness, and refusal to feed. It may be caused by a chill. The sheep should be isolated, well fed on flour gruel, and in mild cases treated with powdered chalk and opium, the quantities in accordance with age, or the cordial recommended for scour in calves may be administered. All cases of looseness in sheep should be watched, and treated immediately.

Hoove. This results from fermentation of food and the production of gas, as in cattle. When a flock is placed on green food or roots, the allowance should be limited until they have become accustomed to the change. A purge of 3 oz. of Epsom salts with a little ginger is advisable, followed by oatmeal gruel, about 4 oz. at a time. If the symptoms do not abate, the trocar and canula may be used as for cattle.

Parturient Fever, or Straining after Lambing. This disease is the result of blood poisoning, often following delivery by the shepherd with hands which have not been disinfected. It is accompanied by fever, the discharge of a dark fluid, pain, and diarrhœa, and is highly dangerous. When assisting a ewe, the shepherd should take the greatest care to purify his hands with diluted carbolic acid, 1 part to 50 of pure water, and if necessary—indeed, it almost follows that it is necessary—the parts may be syringed with a mixture of 1 part of carbolic acid to 10 parts of glycerine. If the affected animal needs a stimulant, two or three tablespoonfuls of whisky or brandy at a time may be given in flour gruel, adding an ounce of tincture of opium if there is diarrhœa.

Liver Rot. This is caused by the action of an organism known as fluke (*Fasciola hepatica*). There is loss of condition, yellowness of the eye, falling off of wool, and diarrhœa. The organism passes through the system of the water snail; hence wet land should be avoided. The assistance of ducks on sheep farms with wet land has been advocated, the birds consuming the snails. On such land salt should always be liberally supplied. When fluke is suspected, the flock should be removed to dry land, and liberally and quickly fed for the table before it is too late. Salt marshes are advantageous.

Maggots. These pests usually appear in colonies during warm, moist weather, if the eggs deposited by the bluebottle fly are not removed or destroyed by the shepherd, who during summer should keep a strict watch on every sheep, especially noticing any action indicating discomfort. If neglected, the maggots will enter the skin, the wool will fall off, and the sheep become ragged and lose condition. Spirits of tar may be freely used.

The pulse of the sheep, which is taken at the heart, beats 75 times per minute, while the temperature of the body is 101° F. When medicine is administered, it should be from a small bottle with a long, narrow neck, the fluid being slowly and gently passed down the right side of the mouth and kept clear of the tongue.

DISEASES OF PIGS

The diseases of pigs which are notifiable to the police are swine fever, foot and mouth disease, and anthrax. The two latter have already been referred to in connection with cattle, and need no further description, the treatment being practically the same for pigs as for young cattle.

Swine Fever. This very destructive and contagious disease should be handled with promptitude and energy. Where any doubt occurs in diagnosis, the veterinary inspector or surgeon should be immediately called in. Affected swine show fever, great thirst, refusal to feed, and a skin patched with purple, especially on the belly. A case should be immediately isolated on presenting such an appearance, and on being declared as swine fever each animal affected should be slaughtered, and others which have been in contact with them isolated and treated under the advice of the Government inspector. Every place occupied by diseased pigs should be thoroughly disinfected. Even the boots of the pig-feeder, the vessels used for feeding, including troughs and pails, all should be cleansed with strong carbolic water.

Husk is a complaint due to the same cause as husk in cattle, and may be similarly treated.

Trichinosis. This parasitic disease, of which too little is known, is, happily, seldom found in his country; the only remedy—*i.e.*, to prevent it spreading—is slaughter.

Inflammation of the Lungs. This is due to exposure and chill, and is accompanied by a dry cough, abnormal breathing, and shivering. In cases where the disease is not severe, and where the condition hardly warrants slaughter, the patient may be kept in a dry, warm sty and rapidly fed for the butcher. It may possibly be found that the liberal use of new milk with good meal will be followed by a rapid increase in weight and the prevention of any serious loss. An affected pig needs exceptionally good feeding and nursing, with dry warmth and plenty of air. A light blister, made by mixing mustard and turpentine, well rubbed over the affected part, is sometimes followed by good results, but this should be accompanied by medicine obtained from the veterinary surgeon.

Measles. This troublesome complaint is accompanied by fever, pustules under the tongue, and red blotches on the skin. The patient should be kept in a warm, dry, well-ventilated sty, supplied with good food, such as milk given slightly warm, together with an ounce of sulphur twice daily.

Rheumatism. This chiefly affects young pigs, which apparently become cramped, especially in the hind limbs. The complaint is caused by lying upon damp beds, hot manure heaps, or even cold stone, concrete, or brick floors with insufficient straw. Wooden benches well covered with dry wheat-straw should be provided, so that the animals can make themselves warm and comfortable. A mixture of turpentine and mustard may be rubbed well into the affected limbs.

Sore Throat. This is a serious complaint, often resulting in death. There is swelling on the throat or neck and tongue, while the membrane of the mouth becomes abnormally dark in colour. The pig rapidly loses condition and strength, and, unless the disease is arrested, death speedily follows. The throat may be fomented, Epsom salts administered at the outset, and the advice of a veterinarian obtained.

A USEFUL MEDICINE CHEST

The following materials should be kept in store by every stock-feeder. They chiefly consist of simple remedies or appliances which any intelligent man may employ upon recognising the complaint which they are intended to relieve. We think, however, that in all serious cases the preparation and administration of medicine should be left entirely to those who have been properly trained for the purpose. In deciding upon the employment of a veterinary surgeon, it may be well to arrange to pay for his services by an annual sum or by definite fees for each visit, to include medicine.

List of Medicines

Condy's Fluid
Tincture of ammonia
Powdered aloes
Epsom salts
Castor oil
Mustard
Sulphur
Powdered catechu
Archangel tar
Foot-rot ointment
Carbolic acid (poison)
Nitre
Spirits of camphor
Linseed oil
Olive oil
Powdered ginger
Prepared chalk
Spirits of tar
Sheep dip
Calf cordial

Instruments and Materials

Trocar and canula
Clinical thermometer
Knee-caps and bandages
Clamps for castration
Twitches for horses
Searing iron

INSECT PARASITES

Ox Warble Fly (*Hypoderma lineata* and *H. bovis*). So terrible have been the ravages of this pest that the damage was once estimated by Ormerod to amount to millions of pounds sterling per annum, and the loss is still very great. The larvæ from the eggs of *H. lineata* [2] find their way into the body in a manner similar to the horse bot [see below], but after wandering through the connective tissue, finally lodge under the hide along the back, forming the well-known "warbles," the hide being perforated, and frequently riddled with the holes caused in this way. Not only may the hide be ruined, but much loss arises through falling off in the milk yield of a cow, or spoiling the carcase from the point of view of the butcher. Stock should have the natural shelter of trees if possible, and be near water which they can enter; while egg-laying by the fly may be prevented in summer by smearing the animals with a strong-smelling, greasy material such as cart-grease and paraffin, or a mixture of 1 quart of train-oil, 4 ozs. of oil of tar, and 4 ozs. of flowers of sulphur. All "bots" found in the backs of stock should be squeezed out and destroyed during the first four months of the year.

Horse Bot Fly (*Gastrophilus equi*). In this case the fly attaches its eggs [6] to the hairs of the neck, sides and shoulders, startling its victim in the act. Irritation is caused by the resulting larvæ, which are licked into the mouth of the horse, and finally find their way to the stomach and intestines, where they cause considerable irritation and inflammation, passing away in the fæces some months later. Rubbing down the horse with a paraffin cloth during June and July may prevent egg-laying. Close clipping should be resorted to, and the coat examined for eggs, which may be removed and destroyed, while infested animals should be well fed.

Sheep Ked and Sheep Tick. These two pests differ widely, though the former is frequently, although improperly, termed "tick." The ked (*Melophagus ovinus*) is a dipterous insect [5] which feeds on the blood and the fatty substance of the wool; the true tick (*Ixodes reduvius*), on the other hand, passes part of its life on vegetation [4], but at one stage it is parasitic on the sheep, sucking the blood in considerable quantity, while in the Border districts ticks act as intermediaries in causing the disease known as Louping Ill. For the ked dipping is resorted to, and is regularly carried out in practice [see also Sheep Scab]. All keds and ticks seen on sheep should be destroyed, and as a preventive measure for ticks the herbage may be burnt in spring, so destroying many ticks.

Among other insect pests of livestock may be mentioned the sheep maggot fly (*Lucilia sericata*), the maggots [3] of which invade the flesh of the back and rump, and are frequently very troublesome; the gad flies (*Tabanidæ*), which worry and startle livestock by sucking their blood and by loud buzzing; and lice (*Pediculidæ*), of which there are many species, young animals being chiefly infested.

ADJECTIVES—continued

Degrees of Comparison. Spanish adjectives have the usual degrees of comparison—positive, comparative, and superlative.

The comparative is formed by adding *más* (more) to the positive. The superlative is formed by adding *muy* (very) to the positive, or by the addition of *ísimo*. Terminal vowels are dropped before this addition. Thus:

POSITIVE.	COMPARATIVE.
vil, vile	*más vil*, more vile
prudente, prudent	*más prudente*, more prudent

SUPERLATIVE.

muy vil, vilísimo, most or very vile
muy prudente, prudentísimo, most or very prudent

The superlative in this form expresses the quality in an absolute degree, but without comparison; when comparison is intended, *el más, la más*, or *lo más*, the most, is used, according to gender, as: *el más prudente*, the most prudent.

NOTE. The neuter article *lo* can be used with any superlative to which the word "thing" or any other word may be added in English, as: *Lo mejor no es siempre lo más divertido*, the best (thing) is not always the most amusing; *lo más fácil no es siempre lo mejor*, the easiest (way) is not always the best.

Adjectives ending in *ble* change the last syllable

Some adjectives ending in *iente* drop the *i* in the superlative:

POSITIVE.	SUPERLATIVE.
ardiente, ardent	*ardentísimo*
ferviente, fervent	*ferventísimo*
luciente, bright	*lucentísimo*

Adjectives ending in *z*, *co*, and *go* take *císimo*, *quísimo*, and *guísimo* in the superlative, as: *feliz*, happy, *felicísimo*; *rico*, rich, *riquísimo*; *vago*, vague, *vaguísimo*.

The following are some of the irregular superlatives:

fuerte, strong, *fortísimo*
cruel, cruel, *crudelísimo*
antiguo, ancient, *antiquísimo*
célebre, celebrated, *celebérrimo*
magnífico, magnificent, *magnificentísimo*
nuevo, new, *novísimo*
sagrado, sacred, *sacratísimo*
sabio, wise, *sapientísimo*

The comparative of superiority is expressed by *más* (more), *que* (than), thus: *Yo tengo más dinero que mi hermano*, I have more money than my brother.

The comparative of equality is expressed by *tan* (as), *como* (as), or *tanto, como*: *Hay tanto oro como plata*, there is as much gold as silver; *tan blanco como la nieve*, as white as snow.

The comparative of inferiority is expressed by *menos* (less), *que* (than): *Tiene menos hijos que hijas*, he has fewer sons than daughters.

When "the more" and "the less" are repeated in a sentence they are rendered by *cuanto más, tanto más, cuanto menos, tanto menos*: *Cuanto más tenemos tanto más queremos*, the more we have the more we want; *cuanto menos tenemos tanto menos necesitamos*, the less we have the less we need.

Besides the comparative and superlative formed according to the rule, the following adjectives have also an irregular form:

POSITIVE.	COMPARATIVE.
bueno, good	*mejor*, better
malo, bad	*peor*, worse
grande, great	*mayor*, greater
pequeño, little, small	*menor*, less, smaller
alto, high	*superior*, higher, superior
bajo, low	*inferior*, lower, inferior

SUPERLATIVE.

optimo, very good
pésimo, very bad
maximo, very great
mínimo, very little, very small
supremo, supreme, very high
intimo, very low

TIVE SUFFIXES

Diminutive and augmentative suffixes are terminations applied to nouns and adjectives modifying their original meaning. Their correct use can only be learned by practice.

Diminutives express smallness in size, affection, pity, or contempt. The chief diminutives are *ico, cico, cito, ecito*—these denote affection, and are always well meant—and *illo, cillo, zuelo*, which denote smallness in size, pity, or contempt. All these diminutives take *a* in the feminine.

Augmentatives express largeness in size, clumsiness, contempt, and disproportion. The chief augmentatives are: *on, azo, ote*, in the masculine, and *ona, aza, ota* in the feminine (these express augmentation only); and *acho, achón*, and *arrón*, which further express clumsiness and contempt.

A double augmentative is sometimes used, as: *picaron*, rogue; *picarono* and *picaronazo*, a great rogue.

NOTE. All words ending in *azo* are not augmentatives; many denote a blow with some weapon, expressed by adding *azo* to the noun, as: *fusil*, gun; *fusilazo*, a gunshot; *pistola*, pistol ; *pistoletazo*, pistol-shot ; *baston*, stick ; *bastonazo*, a blow with a stick. A blow with a sharp weapon is generally expressed by adding *ada* to the noun, as: *puñal*, dagger ; *puñalada*, a dagger thrust ; *lanza*, lance ; *lanzada*, a wound with a lance.

Diminutives are constantly applied to proper names, as : *Juan*, John ; *Juanito*, Johnnie ; *Juana*, Jane ; *Juanita*, Jenny ; *Ana*, Anne ; *Anita*, Annie.

Vocabulary	**Vocabulario**
To take a journey	Ir de viaje
The portmanteau, the dress-basket	La maleta, el mundo
The bag	El saco
To pack	Empaquetar
The carriage to go to the station	El carruage para ir a la estacion
First - class tickets, second-class tickets for the servants	Los billetes de primera clase, los billetes de segunda clase para los criados
The compartment	El compartimiento
The guard	El guarda
To eat or dine in the train	Comer en el tren
To sleep in the train	Dormir en el tren
A reserved compartment	Un compartimiento reservado
To take (with one) a courier and a lady's maid	Llevar consigo un courrier y una doncella
To reach one's destination	Llegar á su destinacion
The hotel	El hotel
To take tickets for the opera	Tomar billetes para la opera
To go to the theatre	Ir al teatro
To go to the shops, to the haberdasher's, to the draper's	Ir á las tiendas, á la merceria, á la tienda de mercader
Silk	Seda
Cloth	Paño
Lace	Encaje
Handkerchiefs	Pañuelos
To go to the confectioner's to eat pastry and ices, and drink lemonade	Ir á la confiteria comer pasteles, y helados, y beber limonada

PROSE EXTRACT V.

From "La Hora de Todos y la Fortuna con Seso" ("The Hour of All, and Fortune no Fool"), by Francisco de Quevedo

FORTUNE'S ANSWER TO THE ACCUSATIONS OF JUPITER

"If the deserving are put on one side, and the virtuous left unrewarded, it is not all my fault; many despise what I offer them, and you blame me for their moderation. Many, for want of putting out their hand to take my gift, let it pass to others who snatch what I never gave. Those who do me violence are more numerous than those whom I make rich. More steal what I deny them than keep what I give them. Many receive from me what they do not know how to keep; they lose it, and say that I took it away from them. Many accuse me of bestowing evilly upon others what had been worse bestowed upon themselves. No man is happy without the envy of many, and no man is unhappy without the contempt of all. This servant has served me constantly; I have not moved a step without her; her name is Occasion; hear her and learn how to judge from a kitchen-wench."

Then said Occasion, reeling her speech off quickly, for fear of inculpating herself: "I am a woman who offers herself to all; many find me, but few make the most of me; I am a female Samson whose strength is in her hair. He who can hang on to my mane knows how to defend himself from the twists and turns of my mistress. I divide and dispose of her gifts, and I am accused because men do not know how to gather them up and enjoy them. Stupidity has scattered these infernal phrases among men: 'Who would have thought it; I did not think; I never noticed; that's all right; what does it matter; that's neither here nor there; to-morrow will do; there's lots of time; there's sure to be a chance; let me alone; I know what I'm about; I'm no fool; let it alone; I can do without it; laugh at all things; I don't believe it; I am sure to get the best of it; it will not fail; the Lord will provide; days are more plentiful than sausages; when one door shuts another opens; that's well and good; what business is it of his; it seems to me; it is not possible; don't tell me; I know all about it; facts will prove; let the world wag; I owe God a death; I should cut a pretty figure; why, certainly; let them say what they like; in for a thousand, in for a thousand five hundred; I can turn my hand to anything; my heart in my hand; we shall see; and what, and but, and perhaps.' And the motto of the obstinate, 'I will go my own way.' These stupidities make mankind presumptuous, lazy and careless."

CONTESTACION DE LA FORTUNA CONTRA LAS ACUSACIONES DE JUPITER

"Si hay beneméritos arrinconados y virtuosos sin premios, no toda la culpa es mia; á muchos se les ofrezco que los desprecian, y de su templanza fabricáis mi culpa. Otros, por no alargar la mano á tomar lo que les doy lo dejan pasar á otros, que me lo arrebatan sin dárselo. Mas son los que me hacen fuerza que los que yo hago ricos; mas son los que me hurtan lo que les niego que los que tienen lo que les doy. Muchos reciben de mi lo que no saben conservar, piérdenlo ellos y dicen que yo se lo quito. Muchos me acusan por mal dado en otros lo que estuviera peor en ellos. No hay dichoso sin invidia de muchos, no hay desdichado sin desprecio de todos. Esta criada me ha servido perpetuamente; yo no he dado paso sin ella; su nombre es la Ocasion; oidla, aprended á juzgar de una fregona."

Y desatando la taravilla la Ocasion, por no perderse á si misma dijo: "Yo soy una hembra que me ofrezco a todos; muchos me hallan, pocos me gozan; soy Sansona femenina, que tengo la fuerza en el cabello. Quien sabe usirse á mis crines sabe defenderse de los corcovos de mi ama. Yo la dispongo, yo la reparto, y de lo que los hombres no saben recoger y gozar, me acusan. Tiene repartidas la necedad por los hombres estas infernales cláusulas: 'Quien dijera, no pensaba, no miré en ello, no sabia, bien está, qué importa, qué va ni viene, mañana se hará, tiempo hay, no faltará ocasion, descuidéme, yo me entiendo, no soy bobo, déjese deso, yo me lo pasaré, ríase de todo, no lo crea, salir tengo con la mia, no faltará, Dios lo ha de proveer, mas dias hay que longanizas, donde una puerta se cierra otra se abre, bueno está eso, que le va á él, paréceme á mi, no es posible, no me diga nada, ya estoy al cabo, ello dirá, ande el mundo, una muerte debo á Dios, bonito soy yo para eso, si por cierto, diga quien dijere, preso por mil, preso por mil y quinientos, todo se me alcanza, mi alma en mi palma, ver veamos, y que, y pero, y quizas.' Y el tema de los porfiados, 'Dé donde diere.' Estas necedades hacen a los hombres presumidos, perezosos y descuidados."

Francisco de Quevedo (1580-1655), poet and satirist. His reputation rests chiefly upon his prose satires, especially upon a series of six called "Visions." In the apologue, from which the above extract is taken, Jupiter summons Fortune before him, and rates her for her injustice towards mankind. After hearing her defence, he resolves to apportion his

Francisco de Quevedo (1580-1655), poeta y satirico. Su reputacion resta principalmente en su prosa sátirica, especialmente sobre una série de seis llamadas "Sueños." En el apólogo del cuál el extracto que precede ha sido tomado, Jupiter cita á la Fortuna y la reprueba por su injusticia hacia la humanidad. Despues de oir su defensa toma la resolucion de

true deserts to every human being for the space of one hour. Such intolerable confusion is the result that Jupiter restores the empire of Fortune, and all is allowed to go on as before.	repartir y dar por una hora á todo ser humano lo que cada cual merece. Resulta tal intolerable confusion que Jupiter restora el imperio de la Fortuna. y es permitido que todo siga como anteriormente.

Key to Exercise IV.

1. Ese hombre es *grande* y esa mujor es tambien *grande*.

2. Ese edificio es hermoso. y esa estatua es *hermosa*.

3. Un *traidor* á su patria. Una *traidora* á su fé.

4. Un español, una española. un inglés y una inglesa hablaban sin entenderse.

5. Un amo *bueno*, y un *buen* criado son raros.

6. La hacienda es productiva.

7. Los toros son bravos.

8. Los potros son numerosos.

9. Las mulas son fuertes.

10. El hacendero es rico.

11. Los labradores son honrados.

12. El gallo canta por la mañana, las gallinas cacarean.

13. La leche y la manteca son frescas.

14. El cazador es buen tirador.

15. La caza es abundante.

16. Los ciervos son ligeros.

17. Los osos y los jaabalies son feroces.

18. El guarda es vigilante.

19. Las medias son de seda, y los zapatos de piel fina.

20. El pañolon es de lana, y tambien lo son los calcetines.

21. Los guantes son de piel de perro.

22. El sastre ha traido mi paletó y mi levita.

23. La costurera ha traido mi vestido.

24. La modista ha traido mi sombrero, y el guantero mis guantes.

25. Buenos días, señor! Buenos días, señora!

46. El colegio es bueno.

27. Tiene una hermosa libreria, y unos libros splendidos.

28. Los manuscritos son antiguos.

By Francesco de Feo

ADJECTIVES

The adjective agrees with the noun in gender and number.

The gender of the adjective is known by its termination.

Adjectives in Italian either end in *o* (*buono*) or in *e* (*diligente*).

1. The form in *o* is used for the masculine gender, as: *vino buono*, good wine; *uomo ricco*, rich man. This form has a corresponding feminine form in *a*, as: *gente buona*, good people; *persona ricca*, rich person.

2. The form in *e* is used both for the masculine and feminine, as: *scolaro diligente*, diligent pupil; *scolara diligente*.

The qualifying adjective is placed *before* the noun when it expresses an innate quality of the noun, as: *la verde campagna*, the green country; *le alte montagne*, the high mountains. It is placed *after* the noun when it expresses a casual and accessory quality of the noun, as: *un cielo sereno*, a clear sky; *un cielo nuvoloso*, a cloudy sky; *un bagno freddo*, a cold bath; *un bagno caldo*, a hot bath.

Note. There are occasional departures from this simple rule, especially when the adjective is used emphatically.

Reading Exercise [Esercizio di Lettura]

Ma la pràtica(1) generale ha voluto(2) che òbblighi(3) soltanto a non confidare(4) il segreto, se non a chi sia un amico ugualmente fidato(5), e imponèndogli(6) la stessa condizione. Così(7), d'amico fidato in(8) amico fidato, il segreto gira e gira(9) per quell' immensa catena, tanto che(10) arriva all' orècchio di colui o di coloro(11) a cui il primo che ha parlato intendeva appunto di non lasciarlo arrivàr mai(12). Avrebbe però(13) ordinariamente a stare(14) un gran pezzo in cammino(15), se ognuno non avesse che(16) due amici: quello che gli dice, e quello a cui ridice la cosa da tacersi(17). Ma ci son degli uòmini privilegiati che(18) li(19) còntano(20) a centinaia; e quando il segreto è venuto a uno(21) di questi uòmini, i giri divengon sì ràpidi e sì moltiplici, che non è più possibile di seguirne la tràccia.(22)

Notes. (Expressions have been chosen which correspond as nearly as possible with the exact meaning of the Italian words): 1. Practice. 2. Determined. 3. That [the condition] binds [the friend]. 4. Not to confide. 5. Unless it be to one who is an equally confidential friend. 6. Binding him also (by). 7. Thus. 8. From confidential friend to. 9. Travels and travels along. 10. So much that. 11. It arrives at the ears of the person or persons (*colui o coloro*). 12. Particularly intended never to allow it to arrive. 13. However. 14. To be. 15. A long while on its way. 16. If everyone had only. 17. The one who tells him, and the one to whom he repeats the thing to be kept secret. 18. Who. 19 Them. 20. Count. 21. Has reached one. 22. Its travels become so rapid and so manifold that it is no longer possible to follow their traces.

Plural of Adjectives. In the formation of the plural the adjectives follow the general rule given for the substantives:

1. Adjectives ending in *o* and in *e* form their plural by changing the *o* and *e* into *i*, as: *buono, buoni*; *caro, cari*; *diligente, diligenti*; *prudente, prudenti*.

2. Adjectives ending in *a* form their plural by changing the *a* into *e*, as: *buona, buone*; *cara, care*.

The adjective *pari* is indeclinable: *I pari miei*, men such as I; *le pari mie*, women such as I, etc.

For the adjectives ending in *co*, *go*, *ca*, *ga*, *io*, see the observations on the plural of nouns.

If the adjective refers in the same sentence to nouns of different genders, it is put in the masculine gender.

NOTE. All the adjectives in Italian may be used as substantives—*e.g.*: *gli uomini buoni*, or simply *i buoni*; *gli uomini cattivi*, or simply *i cattivi*; *un uomo Inglese*, or, which is better, *un Inglese*.

Observations on Certain Adjectives. *Bello* (beautiful, fine) follows the same rules as the article *lo*—*i.e.*, before masculine nouns beginning with a consonant (except *z*, *gn*, and impure *s*) it drops the syllable *lo* in the singular, and becomes *bei* (often written *be'*), in the plural, as: *un bel regalo* (a nice present), *dei bei regali*; *un bel cavallo* (a beautiful horse), *dei bei cavalli*. Before a vowel, in the singular, the final *o* is dropped and the apostrophe is put instead, as: *un bell' orologio*, a fine watch. Before a vowel, *z*, *gn*, and impure *s* in the plural it becomes *begli*, as: *begli occhi*, beautiful eyes. Before feminine nouns it is regular: *bella mano*.

Belli is used only as predicate: *I fiori sono belli.*

Buono (good) in the singular follows the same rules as the indefinite article: *buon uomo, buon libro, buona donna, buono scolaro, buono zio, buon' anima.* In the plural it follows the general rule, as: *buoni uòmini, buone zie*, etc.

Grande (big) becomes *gran* before a consonant and *grand'* before a vowel, as: *gran libro, grand' uomo*; *gran* (or *grande*) *spettàcolo*, *gran* (or *grandi*) *spettàcoli.*

Santo (saint) becomes *san* (masculine) before a proper name beginning with a consonant, and *sant'* before a vowel, as: *san Giòrgio, sant' Andrea.*

Frate (friar) may become *fra* before a consonant, as: *fra Cristòforo.*

Signore (Mr.) drops the final *e* before proper names, as: *Signòr Tale.*

EXERCISE XII.

biondo (*bee-òndo*), fair
bianco (*bee-àhnco*), white
nero (*nehro*), black
rosso, red
verde (*vèhr-deh*), green
fedele (*fehdèh-leh*), faithful
turchino (*toorkeèno*), blue
lungo (*loòngo*), long
corto, short
stanco, tired

neve (*nèhveh*), snow
inverno (*een-vèhrno*), winter
estate (*eh-stàhteh*), summer
finestra (*feenèhstrah*), window
barba, beard
mondo, world
bandiera (*bahndee-èhrah*), flag
letto (*lèhtto*), bed

1. Una casa bianca. 2. La bianca neve. 3. Il freddo inverno. 4. Un abito nero. 5. Capelli neri. 6. Quella ragazza ha gli occhi turchini e i capelli biondi. 7. Nella grande strada a destra vi è un gran bel palazzo con le finestre verdi. 8. I ricchi hanno sempre amici fedeli. 9. Il leone e la tigre sono animali feroci. 10. Fra Cristoforo aveva la barba bianca e lunga. 11. Gli àlberi sono càrichi di frutte. 12. Nel mondo vi sono i buoni e i cattivi. 13. Bianco rosso e verde sono i colori della bandièra italiana. 14. La nostra casa è in via sant' Andrea. 15. La figlia della padrona di casa ha begli occhi, ma brutti capelli. 15. Le giornate sono corte d'inverno e lunghe d' estate. 17. I ragazzi e le ragazze sono andati a letto, perchè èrano molto stanchi.

Demonstrative Adjectives. The demonstrative adjectives are: *questo* (this), *codesto* (that . . . of yours), *quello* (that), *stesso*, *medèsimo* (same), *tale* (such), *altro* (other), *quale?* (which ?).

Questo indicates a person or thing near or considered as near the person who is speaking, as: *questo cappello, questo libro. Sta* in some cases stands for the feminine *questa*, and is generally written in one word with the noun, as: *stasera* (this evening), for *questa sera*; *stamattina* (this morning), for *questa mattina.*

Codesto indicates a person or thing near or considered as near the person who is listening, as: *codesto orologio, codesto àbito.*

Quello indicates a person or thing distant, or considered as distant, from both the person who is speaking and the one who is listening, as: *quell' uomo* (that man), *quel quadro* (that picture).

Questo and *codesto* form their feminine and plural regularly: *questi libri* (these books), *codeste parole* (those words . . . of yours). *Quello* has the same forms as *bello*: *quel libro, quello scolaro, quei libri, quegli scolari, quell' erba, quell' uomo*; *un libro come quelli* (a book like those).

Questo and *quello* represent also the English the latter, the former, respectively, as: *Ho ricevuto un libro inglese e un libro italiano; quello non lo capisco, questo l' ho già letto* (I have received an English book and an Italian one; the former I do not understand, the latter I have already read).

As in English these adjectives never take the article: *a quest' ora, di quel tempo. Lo stesso, il medèsimo* are used as in English: *la medèsima cosa*, the same thing; *allo stesso tempo*, at the same time.

Stesso and *medèsimo* represent also the English *myself*, *himself*, *herself*, etc., in expressions like: *L' ho visto io stesso*, I have seen it myself; *La signora stessa l' ha detto*, the lady herself has told it.

Tale is often the correlative of *quale* (plural *tali* and *quali*). Example: *Tal* (*e*) *padre, tal*(*e*) *figlio* (like father, like son).

Quale i' fui vivo, tal son morto (Dante Inf., c. xiv., v. 51), Such as I was when alive, such I am also now that I am dead.

Altro is used as in English. Example: *Credevo che fossi un altro uomo*, I thought you were another man. *Pòrtami il libro*, bring me the book. *Èccolo*, here it is. *No; non questo, l'altro*, no; not this one, the other.

EXERCISE XIII.

1. Questo bagàglio, non quello. 2. Questi fiori sono per voi. 3. Codeste parole sono molto cortesi. 4. Abbiamo detto tutt' e due (both) la

'stessa cosa. 5. Quegli scolari non hanno carta. 6. Queste case e questi giardini sono d'un Inglese. 7. Gli alberghi in questa città non sono molto còmodi. 8. Quei quadri e quelle stàtue sono l'òpera d'un grand' artista. 9. Quanto (how much) avete pagato codesto bastone? è molto bello. 10. Io non rispondo (answer), perchè codesti discorsi non m'interèssano. 11. Misi (I put) io stesso la lèttera alla posta, eppure l'avvocato ha detto che non l'ha ricevuta. 12. Queste frutta non sono mature; non sono le stesse che (which) avete mandate a casa stamattina.

KEY TO EXERCISE XI.

1. If I had. 2. If I had not? 3. That he (may) have. 4. That he (may) be. 5. That you (may) be. 6. If we were not? 7. If I were not. 8. They would be. 9. They would have had. 10. If I had had time, I would have come. 11. If I were . . . I would have. 12. He would be . . . if they had not been . . . 13. If I have time (literally, having time) . . . I shall be . . . 14. They are poor, but (they) would be rich, if (they) had had . . . 15. To have. 16. Of having. 17. Have patience. 18. Be good.

By Louis A. Barbé, B.A.

RELATIVE PRONOUNS

There are two forms of relative pronouns, the uninflected and the inflected.

The uninflected relative pronouns are:

qui, who, which, that, whom (after a preposition); *que*, whom, which, that; *quoi*, which; *dont*, whose, of whom, of which; *où*, in which, into which, at which, to which, etc.

The inflected relative pronouns are:

lequel (mas. sing.), *lesquels* (mas. pl.), who, whom, which, that; *laquelle* (fem. sing.), *lesquelles* (fem. pl.), who, whom, which, that.

The definite article is contracted in the same way as when it precedes a noun: *duquel, auquel, desquels, auxquels, desquelles, auxquelles*.

The relative pronoun, whether inflected or uninflected, is of the same gender, number, and person as its antecedent. In the case of the uninflected relative, there is nothing in the pronoun itself to show this agreement; but it affects the number and person of the verb of which the relative is the subject, and the number and gender of adjectives and past participles referring to the relative: *Les amis qui nous accompagnent connaissent bien Paris*, The friends who accompany us know Paris well.

Il y a dans ce livre une histoire qui est très intéressante, In that book there is a story which is very interesting.

1. *Qui*, as the subject of a verb, may refer to either persons or things:

Le marchand qui vous a vendu ces objets est très accommodant, The shopkeeper who sold you those objects is very obliging;

Il donne de l'eau à son cheval qui est très altéré, He is giving water to his horse, which is very thirsty.

When preceded by a preposition *qui* refers to persons only. For animals and inanimate objects the inflected relative must always be used after a preposition:

L'enfant à qui tout cède est le plus malheureux, The child to whom everything (every one) yields is the most wretched.

C'est une condition sans laquelle je ne consentirai à rien, That is a condition without which I shall not consent to anything.

2. *Que* is used as a direct object (accusative), and may refer to persons or things:

Voici les amis que nous attendions, Here are the friends we were expecting.

Je lis le livre que vous m'avez prêté, I am reading the book which you lent me.

The *e* of *que* is elided before a word beginning with a vowel or unaspirated h.

The *i* of *qui* is never elided; consequently, *qu'* always stands for *que*:

J'ai reçu la lettre qu'il m'avait promise, I have received the letter which he had promised me.

In English, the relative pronoun has distinct forms for subject and object only when it refers to persons: "who," "whom." When it refers to animals or things, it has only the one form "which" for both cases.

The fruit which is on that tree (nominative).

The fruit which that tree produces (objective).

In French, each case having its special form and not being dependent on position, the object is frequently placed immediately before the verb. Thus, "The fruit which that tree produces" may be rendered either by:

Le fruit que cet arbre produit, or *Le fruit que produit cet arbre*.

In English, the relative pronoun as object is very often omitted. In French it must always be expressed:

The pupil you have scolded, *L'élève que vous avez grondé*;

The exercises you have corrected, *Les devoirs que vous avez corrigés*.

3. *Quoi* is used as an indirect object—*i.e.*, after a preposition. Its antecedent is rarely a noun, but rather a statement, or some indefinite expression, such as *quelque chose*, something; *rien*, nothing; *voilà*, that is:

Il n'y a rien sur quoi l'on ait plus écrit, There is nothing about which more has been written.

Voilà de quoi je voulais vous parler, That is what I wished to speak to you about.

If the antecedent is a noun it is better to use the inflected relative with the preposition:

C'est la chose à laquelle je pense le moins, That is the thing I think least about.

4. *Dont* is equivalent to the relative pronoun and the preposition *de* (of, from), thus:

Le livre dont vous m'avez fait présent, The book of which you have made me a present.

Les amis dont vous avez méprisé les conseils, The friends whose advice you have despised.

In English, the noun dependent on "whose" always follows it, whether it be subject or object, and is never accompanied by a definite article. In French, it has always a definite article, and comes immediately after *dont* only when it is the subject of the relative clause. If it is the object of that clause it comes after the verb:

La maison dont le gérant m'a écrit, The firm whose manager has written to me;

La maison dont j'ai vu le gérant, The firm whose manager I have seen.

When "whose" is preceded by a preposition, it cannot be translated by *dont.* The inflected form of the relative must be used:

La maison au gérant de laquelle j'ai écrit, The firm to whose manager I have written.

5. *Où,* though really an adverb, is frequently used as the equivalent of a relative and one of the prepositions "in," "into," "at," "to," etc.:

La maison où il est né, The house where (in which) he was born.

It may be preceded by *de,* and used instead of *dont,* to indicate "place whence":

Le village d'où nous venons, The village from which we come.

Only *dont,* and not *d'où,* must be used to indicate descent:

La famille dont il descend est honorable, The family from which he descends is honourable.

NOTES. The relative pronoun with *ce* as its antecedent forms the absolute "what":

Ce qui est vrai n'est pas toujours agréable, What is true is not always pleasant.

Je vous répète ce que l'on m'a dit, I repeat to you what I have been told.

Prenez ce dont vous avez besoin, Take what you have need of.

When the verb is in the infinitive, "what" is *que:*

Je ne sais que faire, I do not know what to do.

The demonstratives *celui, celle, ceux, celles,* are used before the relative instead of the English personal pronouns, "he," "she," "they," and also instead of "the one":

Le meilleur ami est celui qui nous dit la vérité, The best friend is he who tells us the truth.

The demonstrative antecedent may be omitted, as in English:

Qui vivra verra, He who lives (long enough) shall see.

When "which" has a whole clause for its antecedent in English, the relative must be preceded by *ce* in French:

J'ai perdu ma valise, ce qui est fort contrariant, I have lost my portmanteau, which is very provoking.

INTERROGATIVE PRONOUNS

The interrogative pronouns are:

Qui? who? whom? *De qui?* whose? *À qui?* whose? *Qu'est-ce qui? Quoi?* what? *Lequel? lesquels?* (mas.), which? which one? *Laquelle? lesquelles?* (fem.) which? which ones? *Que? qu'est-ce que?* what?

1. *Qui,* as an interrogative pronoun, is both subject and object:

Qui vous a donné cela? Who gave you that?
Qui cherchez-vous? Whom are you looking for?

Qui? may be preceded by a preposition:

Pour qui me prenez-vous? For whom do you take me?

There is also a periphrastic form:

qui est-ce qui? who?
qui est-ce que? whom?

Qui est-ce qui vous a donné cela? Who (is it who) has given you that?

Qui est-ce que vous cherchez? Whom are you looking for?

When this form is used no inversion of the subject and verb is required to mark the interrogation.

"Whose?" is never expressed by *dont.* When it denotes ownership and is equivalent to "to whom belongs?" it is rendered by *à qui?*

Whose key is this? *à qui est cette clef?*

In any other case *de qui?* is used:

De qui est-il (le) fils? Whose son is he?

2. *Qu'est-ce qui?* "What" as the subject of an interrogative sentence has only the periphrastic form, *qu'est-ce qui?*:

Qu'est-ce qui vous empêche de venir avec nous? What prevents you from coming with us?

In indirect questions it becomes *ce qui:*

Je vous demande ce qui vous empêche de venir avec nous. I ask you what prevents you from coming with us.

3. *Que?* what? is used as the object or the predicate of a verb:

Que dites-vous? What do you say? *Qu'est-ce?* What is it? *Qu'est-il?* What is he?

Que deviendrons-nous? What will become of us? (What shall we become?)

There are also two periphrastic forms:

Qu'est-ce que? and *qu'est-ce que c'est que?* neither of which requires inversion of subject and verb:

Qu'est-ce qu'il dit? What does he say?

Qu'est-ce que c'est que ça (cela)? What is that?

In indirect questions *qu'est-ce que* becomes *ce que:*

Je vous demande ce que vous faites, I ask you what you are doing.

4. *Quoi?* is usually the indirect object of an interrogative sentence, and is preceded by a preposition:

Avec quoi avez-vous ouvert ce tiroir? With what have you opened that drawer?

It may also be used absolutely as either the subject or the object of a verb understood:

Il y a quelque chose dans ce tiroir. Quoi? There is something in that drawer. What?

J'ai mis quelque chose dans ce tiroir. Quoi ? I have put something into that drawer. What ?

Quoi ? followed by an adjective in the comparative, preceded by *de*, is used as the subject of *est* understood :

Quoi de plus honteux que le mensonge ? What more shameful than lying ?

Quoi ? may also be used, as more emphatic than *que ?* with a verb in the infinitive :

Quoi faire ? What to do (is to be done) ?

5. *Lequel ? laquelle ? lesquels ? lesquelles ?* which ? which of ? express distinction or selection :

Lequel de vos frères vous a écrit ? Which of your brothers has written to you ?

De ces deux montres laquelle préférez-vous ? Of these two watches, which do you prefer ?

"What" Relative or Interrogative

The various ways of translating "what," whether relative or interrogative, are:

1. *Quel, quelle, quels, quelles.*

Quel livre lisez-vous ? What book are you reading ?

Quelle heure est-il ? What time is it ?

Quels sont les quatre points cardinaux ? What are the four points of the compass ?

Quelles belles gravures ! What fine engravings !

Je ne sais pas quels romans vous avez lus, I do not know what novels you have read.

2. *Qu'est-ce qui, ce qui, ce que.*

Qu'est-ce qui vous empêche de sortir ? What prevents you from going out ?

Je vous demande ce qui vous empêche de sortir, I ask you what prevents you from going out.

Je sais ce que je veux, I know what I want.

3. *Que, qu'est-ce, qu'est-ce que, qu'est-ce que c'est que.*

Que dites-vous ? What do you say ?

Qu'est-ce ? What is it ?

Que deviendrons-nous ? What will become of us ?

Qu'est-ce qu'il dit ? What does he say ?

Je vous demande ce qu'il dit, I ask you what he says.

Qu'est-ce que la grammaire ? What is grammar ?

Qu'est-ce que c'est que ça ? What is that ?

4. *Quoi.*

Avec quoi avez-vous ouvert ce tiroir ? With what have you opened this drawer ?

Il y a quelque chose dans ce tiroir. Quoi ? There is something in that drawer. What ?

J'ai mis quelque chose dans ce tiroir. Quoi ? I have put something in that drawer. What ?

Quoi de plus honteux que le mensonge ? What more shameful than lying ?

Quoi faire ? What is to be done ?

EXERCISE XX.

VOCABULARY

abricot (m.) apricot
abricotier (m.) apricot-tree
aliment (m.) food (food-stuff), kind of food
asperge (f.) asparagus
avoine (f. s.) oats (pl.)
la bécasse, woodcock
la bécassine, snipe
la betterave, beetroot
le blé, corn
la boucherie, butcher's shop, meat market
le boulanger, baker
le brochet, pike
le brugnon, nectarine
le canard, duck
la carpe, carp
la carotte, carrot
le cerf, stag
la cerise, cherry
le cerisier, cherry-tree
la chair, flesh
le chasseur, sportsman, hunter
le chevreuil, roebuck
le chou, cabbage
le cidre, cider
le coq de bruyère, grouse
le dindon, turkey
eau douce, fresh water
éperlan (m.), smelt
espèce (f.), kind
étang (m.), pond
le faisan, pheasant
la farine, flour
la faux, scythe
la fève, bean
le filet, net
le fruit, fruit
le fusil, gun (fowling-piece)
le gibier, game
le hareng, herring
le haricot, haricot-beans
le lac, lake
le légume, vegetable
le levain, yeast
le lièvre, hare
la ligne, line
la machine, machine, machinery
le maquereau, mackerel
la mer, sea
le merlan, whiting
le meunier, miller
le moissoneur, reaper
la morue, cod
le moulin, mill
le mouton, sheep
la nourriture, food (sustenance)
oie (f.), goose
oiseau (m.), bird
orge (f.), barley
le pain, bread
la pâte, dough
le paysan, peasant
la pêche, peach
le pêcher, peach-tree
le pêcheur, fisher, fisherman
la perche, perch
la perdrix, partridge
la plante, plant
la poire, pear
le poirier, pear-tree
le pois, pea
le poisson, fish
le poisson de mer, salt-water fish
la pomme de terre, potato
le pommier, pear-tree
le potager, vegetable garden, kitchen garden
la poule, fowl
la prune, plum
le prunier, plum-tree
la raie, skate
le raisin, grape
le ruisseau, brook
le sanglier, wild boar
le saumon, salmon
le seigle, rye
la sole, sole
le terrain, plot of ground
la truite, trout
le turbot, turbot
le veau, calf
le verger, orchard
la viande, meat
la viande de boucherie, butcher's-meat
la vigne, vine
le vin, wine
la volaille, poultry

---

connu, known
délayé, mixed
différent, different
frais, new (of bread)
fruitier, fruit (fruit-bearing)
principal, principal
rassis, stale

---

avec, with
oui, yes
pour, for, in order to, to

ajouter, to add
attraper, to catch
changer, to change
cultiver, to cultivate
faucher, to mow
faire, to make
manger, to eat
nommer, to call
tuer, to kill

---

il fait, he makes
il produit, it produces
ils servent, they serve
ils croissent, they grow

TRANSLATE INTO FRENCH

[In the following exercise passive forms are to be rendered by *on* and an active verb: "the animals of which the flesh is eaten," *les animaux dont on mange la chair.*]

What are the principal kinds of food which serve for (*à*) the sustenance of man ? They are bread, meat, poultry, game, fish and vegetables. What is the plant which is cultivated to make bread (of it) ? It is corn. Who cultivates corn ? Peasants cultivate it. What are the principal kinds of corn ? They are wheat, oats, barley, and rye. Who are those who mow the corn ? The reapers. With what ? With scythes. Into (*en*) what is corn changed to make bread (of it) ? Into flour. Who is it that changes corn into flour ? It is the miller. What is a mill ? It is the machinery with which the miller changes corn into flour. What is dough ? It is flour mixed with water. What is added to dough ? Yeast is added to it. Who makes bread ? It is the baker who makes bread. What is stale bread ? Bread which is not new. What are the animals of which the flesh is eaten ? They are the ox, the calf, the sheep. What is butcher's-meat ? It is the flesh of domestic animals. What is game ? We call game the animals which are not domestic animals and of which the flesh is eaten. What are they ? The stag, the roebuck, the wild boar, the hare. Who are they who kill those animals ? They are sportsmen. With what do they kill them ? With guns. Is the flesh of birds eaten ? Yes, there are some birds of which the flesh is eaten. Which ? Fowls, turkeys, ducks, and geese. Are there any other birds of which the flesh is good to eat ? Yes, there are other birds of which the flesh is good to eat ; they are wild birds, such as the partridge, the woodcock, the snipe, the pheasant and grouse. What are the different kinds of fish ? There are salt-water fish and fresh-water fish. What is fresh water ? The water of lakes, ponds, rivers and streams. What are the best-known sea-fish ? They are (the) cod, herring, smelt, mackerel, sole, turbot, whiting and skate. And the fresh-water (those of fresh-water) ? Salmon, trout, carp, perch, and pike. Who are those who catch fish ? They are fishers. With what ? With lines and nets. What is eaten with meat ? Vegetables. What are vegetables ? They are plants that also serve for the sustenance of man. What are the principal vegetables that are cultivated in France ? Potatoes, cabbages, beetroot, carrots, asparagus, beans, haricot-beans, and peas. What is a kitchen garden ? It is the garden or plot of ground where vegetables are cultivated. And an orchard, what is that ? It is the plot of ground in which there are fruit-trees. What are the principal fruit-trees and their fruit ? The pear-tree, of which the fruit is the pear ; the cherry-tree, which produces cherries ; the peach-tree, on which peaches grow ; the nectarine, of which the fruit has the same name as the tree ; the plum-tree and the apricot-tree, which give us plums and apricots ; and the apple-tree, with the fruit of which cider is made. What is the plant which is cultivated to make wine (of it) ? It is the vine. What is the fruit of the vine ? It is the grape.

KEY TO EXERCISE XIX.

Vous me demandez l'histoire de mon bouvreuil ; la voici. Un de mes amis a une maison à la campagne. Je passe quelquefois l'hiver chez lui. Moi, j'aime la campagne en hiver ; vous aimez mieux la ville, vous. Chacun son goût. Il y a deux ans j'y ai fait un séjour de plusieurs mois, et pendant que j'y étais j'ai fait la connaissance d'un bouvreuil. Il était un peu plus gros qu'un moineau. Il avait le bec épais, noir et dur. Ses petits yeux avaient une expression aimable. Je n'ai jamais vu de plumage plus beau, plus lustré que le sien. Il avait la tête noire et la poitrine presque aussi rouge que celle d'un rouge-gorge. Il avait les ailes tachetées de rouge aussi. Il avait la voix douce et je n'ai jamais entendu de sons plus moelleux et plus variés que ceux qu'il filait. Il m'égayait et me charmait. Je le soignais, je le caressais. Quand on m'apportait mon déjeuner je lui donnais le sien aussi. Je lui donnais tout ce qu'il aimait le plus : des miettes de pain, de petits morceaux de biscuit et de sucre. Il les becquetait dans ma main. Nous étions (de) bons amis, lui et moi. L'hiver était rude, mais cela ne nous inquiétait pas. Un bon feu flambait dans la cheminée. Nous avions une ample provision, moi de livres, lui de chenevis. Nous étions heureux l'un et l'autre. Nous étions contents l'un de l'autre. Pour les oiseaux une cage n'est souvent qu'une prison. La sienne n'était qu'une chambre à coucher. La porte en était toujours ouverte. Presque toute la journée il vagabondait à travers la chambre. Elle n'était pas plus à moi qu'à lui. Quelquefois il voletait autour de moi. Il sautait sur mon épaule et même sur ma tête (Il me sautait sur l'épaule et même sur la tête). Il m'ébouriffait les cheveux. Cela l'amusait et moi aussi. C'était un gai compagnon. Je n'en ai jamais eu de plus gentil que celui-là. Je ne passais pas toutes mes soirées avec lui. Quand je rentrais je le trouvais endormi. Le bruit de mes pas l'éveillait. Il me saluait par un petit gazouillement. Le lendemain, moi, j'étais éveillé par mon petit ami. Mais la fin de mon histoire est quelque chose de bien triste. Un jour le bouvreuil trouve la croisée entre-baillée. Pendant que j'ai le dos tourné il passe vite dehors. A vingt pas de la maison il y a un gros fumier jaune et noir où une demi-douzaine de poules grattent et becquètent. Ce n'est rien de beau, mais c'est quelque chose d'intéressant pour lui. Du rebord de la fenêtre il vole sur le fumier. Mais c'est un intrus. Les poules ont l'humeur intolérante et hargneuse. La vue du bouvreuil les fâche. Elles l'entourent, le houspillent, l'attaquent. Le bruit m'attire. Je regarde par la croisée. C'est lui ; c'est mon pauvre bouvreuil. J'enjambe la fenêtre ; je vais au secours de mon petit compagnon. Je chasse les poules. Je le tire de leurs griffes. Il est trop tard. Mon pauvre petit compagnon est mort.

XLII. Strong Verbs. The following strong verbs change the stem-vowel -ei- into -i- or -ie- in the imperfect and past participle. Those verbs which are made prominent in print are conjugated with ſein, all others with haben.

Infinitive		Present Tense	Imperfect		Imperative	Past Participle
		I., II., III. Singular	*Indicative*	*Conjunctive*		
beflei'ßen	to bestow pains upon a thing, to apply one's self to	ich befleiß-e, -eſt, -t	ich befliß	ich befliſſe	befleiß(e)	befliſſen
beißen	to bite	ich beiß-e, -eſt, -t	ich biß	ich biſſe	beiß	gebiſſen
bleiben	to remain	ich bleib-e, -ſt, -t	ich blieb	ich bliebe	bleib(e)	geblieben
erblei'chen*	to die, to turn pale	ich erbleich-e, -ſt, -t	ich erblich'	ich erbliche	erbleich(e)	erblichen
gedei'hen	to thrive	ich gedeih-e, -ſt, -t	ich gedieh	ich gediehe	gedeih(e)	gediehen
gleichen	to equal	ich gleich-e, -ſt, -t	ich glich	ich gliche	gleich(e)	geglichen
gleiten	to slide, glide	ich gleit-e, -eſt, -et	ich glitt	ich glitte	gleit(e)	geglitten
greifen, ergreifen	to seize, catch, lay hold on	ich greif-e, -ſt, -t	ich griff	ich griffe	greif(e)	gegriffen
kneifen	to pinch	ich kneif-e, -ſt, -t	ich kniff	ich kniffe	kneif(e)	gekniffen
leiden	to suffer	ich leid-e, -eſt, -et	ich litt	ich litte	leide	gelitten
leihen	to lend	ich leih-e, -ſt, -t	ich lieh	ich liehe	leih(e)	geliehen
meiden	to shun	ich meid-e, -eſt, -et	ich mied	ich miede	meide	gemieden
pfeifen	to whistle	ich pfeif-e, -ſt, -t	ich pfiff	ich pfiffe	pfeif(e)	gepfiffen
preiſen	to praise	ich preiſ-e, -eſt, -t	ich pries	ich prieſe	preiſ(e)	geprieſen
reiben	to rub	ich reib-e, -ſt, -t	ich rieb	ich riebe	reib(e)	gerieben
reißen	to tear	ich reiß-e, -eſt, -t	ich riß	ich riſſe	reiß(e)	geriſſen
reiten†	to ride	ich reit-e, -eſt, -et	ich ritt	ich ritte	reit(e)	geritten
ſcheiden	to depart	ich ſcheid-e, -eſt, -et	ich ſchied	ich ſchiede	ſcheide	geſchieden
ſcheinen	to shine, seem	ich ſchein-e, -ſt, -t	ich ſchien	ich ſchiene	ſchein(e)	geſchienen
ſchleichen	to sneak, crawl	ich ſchleich-e, -ſt, -t	ich ſchlich	ich ſchliche	ſchleich(e)	geſchlichen
ſchleifen‡	to sharpen, grind	ich ſchleif-e, -ſt, -t	ich ſchliff	ich ſchliffe	ſchleif(e)	geſchliffen
ſchneiden	to cut	ich ſchneid-e, -eſt, -et	ich ſchnitt	ich ſchnitte	ſchneid(e)	geſchnitten
ſchreiben	to write	ich ſchreib-e, -ſt, -t	ich ſchrieb	ich ſchriebe	ſchreib(e)	geſchrieben
ſchreien	to shout	ich ſchrei-e, -ſt, -t	ich ſchrie	ich ſchriee	ſchrei(e)	geſchrieen
ſchreiten	to stride	ich ſchreit-e, -eſt, -et	ich ſchritt	ich ſchritte	ſchreit(e)	geſchritten
ſchweigen	to keep silence	ich ſchweig-e, -ſt, -t	ich ſchwieg	ich ſchwiege	ſchweig(e)	geſchwiegen
ſpeien	to spit, vomit	ich ſpei-e, -ſt, -t	ich ſpie	ich ſpiee	ſpei(e)	geſpieen
ſteigen	to rise, mount, ascend	ich ſteig-e, -ſt, -t	ich ſtieg	ich ſtiege	ſteig(e)	geſtiegen
ſtreichen	to stroke	ich ſtreich-e, -ſt, -t	ich ſtrich	ich ſtriche	ſtreich (e)	geſtrichen
ſtreiten	to quarrel	ich ſtreit-e, -eſt, et	ich ſtritt	ich ſtritte	ſtreit(e)	geſtritten
treiben	to drive, press	ich treib-e, -ſt, -t	ich trieb	ich triebe	treib(e)	getrieben
verblei'chen	to fade, to decease	ich verbleich-e, -ſt, -t	ich verblich	ich verbliche	verbleich(e)	verblichen
verzei'hen	to forgive	ich verzeih-e, -ſt, -t	ich verzieh	ich verziehe	verzeih(e)	verziehen
weichen §	to yield, give way	ich weich-e, -ſt, -t	ich wich	ich wiche	weich(e)	gewichen
weiſen	to show, point out	ich weiſ-e, -eſt, -t	ich wies	ich wieſe	weiſe	gewieſen
zeihen	to accuse	ich zeih-e, -ſt, -t	ich zieh	ich ziehe	zeih(e)	geziehen

* To die: strong; to turn pale: weak—examples: er erblich' and er erbleich'te; as transitive bleichen (to bleach) takes weak inflections: er hat die Leinwand gebleicht, he has bleached the linen.

† Reiten is conjugated with ſein and haben; the rules of the alternative conjugations will follow later.

‡ Schleifen in the sense of to trail, to pull along, and to demolish, is weak: der Wagen, die Feſtung wurde geſchleift, the carriage was pulled along, the fortress was pulled down; but: das Meſſer wurde geſchliffen, the knife was sharpened. Schleifen in the sense of "to skate," or "to dance" also takes weak inflections.

§ Erwei'chen, to soften, mollify, touch, is weak.

XLIII. Plural of Compound Nouns. As a rule the last word only of compound nouns takes the plural: der Nacht-Schmetterling (*sing.*) the night-butterfly, die Nacht-Schmetterlinge (*pl.*); das Bauernweib (*sing.*) the peasant-woman, die Bauernweiber (*pl.*). Several compound nouns contain already in the singular words used in the plural: die Töchterſchule (*sing.*), the school for girls [daughters]; der Bücherwurm, the bookworm; der Bilderſaal, the picture-gallery. The plural of these is formed in the usual way by changing the number of the last word; die Töchterſchulen, etc.

1. Several compounds with -Mann (man) form an irregular plural with -Leute (folk, people): der Hauptmann (*sing.*) the captain, die Hauptleute (*pl.*); der Kaufmann (*sing.*) the merchant, die Kaufleute (*pl.*); der Seemann, the sailor, die Seeleute (also die Seemänner), etc. Others form the regular plural with -Männer—examples: der Staatsmann, the statesman, die Staatsmänner; der Gewährsmann, the warranter, surety, guarantee, die Gewährsmänner; der Ehrenmann, the man of honour, die Ehrenmänner, etc.

2. The application of the plural -leute or -männer confers a different meaning to several words belonging to this class: Dienſtmänner (*pl.*) messengers, and Dienſtleute (*pl.*) servants; Ehemänner (*pl.*) husbands, and Eheleute, husband and wife. The substantive der Bauer, the peasant, forms the regular plural die Bauern, and also the compound plural die Bauersleute, denoting peasants of both sexes.

XLIV. Plural of Nouns of Measure. Substantives of measure, when used after cardinal numbers and in a collective sense, generally retain the form of the singular in the plural: fünfzig Pfund (*sing.*) ſchwer, fifty pounds [heavy] of weight; zwanzig Stück (*sing.*) Tuch, twenty pieces of cloth; 16 Fauſt (*sing.*) hoch, 16 ["fists"] hands high; 4 Sack (*sing.*) Kaffee, 4 bags of coffee; 100 Mann (*sing.*) Garde, 100 men of the Guards; fünf Dutzend (*sing.*) Federn, five dozen pens, etc.

1. The nouns of measure of *feminine* gender, ending in an unstressed -e, always form the plural by adding an -n: fünf Flaſche-n (*pl.*) Wein, five bottles of wine; zehn Meile-n (*pl.*) weit, ten miles distant; acht Kiſte-n Indigo, eight boxes of indigo; 50 Tonne-n (*pl.*) Eiſen, 50 tons of iron; die Million (*sing.*) forms the plural die Million-en.

2. Nouns indicating the measure of time always form their plural with an inflection: das Kind iſt ſechs Jahr-e, drei Monat-e und vier Tag-e alt, the child is six years, three months and four days old.

XLV. Conjunctions. These serve either to co-ordinate or to subordinate clauses or words. In *co-ordination* the joined sentences retain their full independence and their original weight, the structure of the sentences joined by the conjunction remaining unaltered. Conjunctions of this class are:

und, and
ſowohl' . . . . . als,
as well . . . . . as
deſſen un'geachtet, nevertheless
den'noch, yet
aber, but
allein', but, only
o'der, or
ſon'dern, but
einerſeits . . . anderſeits,
on the one hand,
on the other hand
darum, deshalb, therefore
nämlich, namely

Examples: Die Sonne ſcheint, die Blumen blühen und die Vögel ſingen, the sun shines, the flowers bloom, and the birds sing, etc.

The *subordinative* conjunctions connect two sentences, one of which is subordinated to the other. The subordinate clause is not complete in itself, and has no sense if detached from the sentence on which it depends Conjunctions of this class are:

daß that
ſo daß, so that
ohne daß, without
auf daß, damit, so that
als, da, wie, as, than
inwiefern, inſofern,
in so far as
während, whilst
ſeit, since
je nachdem, according to
als ob, as if, as though
ob, whether
wenngleich, obgleich,
although
gleichwie, as
nachdem, after
bis, till, until
ehe, bevor, before
weil, because
wenn, if, when
falls, in case
etc.

1. The border-line which separates conjunctions, adverbs, and prepositions is not very distinct; adverbs are often used as conjunctions, and conjunctions as prepositions—for instance: während signifies "whilst" and "during." Example: Wir wanderten während der Nacht, we wandered during the night; and der Tag war ſchön, während die Nacht regneriſch war, the day was fine, whilst the night was rainy.

2. The following interrogative pronouns are classed among the conjunctions if they are used to connect relative or subordinate clauses:

wo, where
womit, wherewith
worin, in which,
wherein
wie, how
worauf, whereupon,
upon which
wobei, whereat, at which
woher, whence
weshalb, wherefore
wohin, where to, whither
wann, when
warum, why
weswegen, wherefore

Examples: Dies war es, worin ich bei'ſtimmte. It was that, to which [whereto] I assented; ich verſtand nicht, worauf er an'ſpielte, I did not understand to what he alluded.

3. If the conjunction introduces the subordinate clause the verb must be placed at the end; in compound tenses the auxiliary verb occupies the last place: Er ſah mich, ehe ich ihn ſah, he saw me before I saw him; and er ſah mich, ehe ich ihn geſehen hatte, he saw me before I had seen him; er ſchlief, als wir kamen, he slept when we came; and er ſchlief, als wir gekommen waren, he slept when we had come.

4. If the subordinate clause with the conjunction is placed at the beginning of the complex sentence, the verb in the second sentence must *precede* the subject: Ehe er mich ſah, ging (verb) ich (subject) fort, before he saw me, I went away; als ſie ab'reiſte, war (verb) es (subject) ſchon

dunkel, when she departed, it was already dark. If the same sentences are reversed, subject and verb resume their normal position in the principal sentence: Ich ging fort, ehe er mich ſah; es war ſchon dunkel, als ſie abreiſte.

EXAMINATION PAPER XII.

1. Which vowels are taken in the imperfect and in the past participle by strong verbs with the stem-vowel -ei-?
2. Under what circumstances do certain verbs in this group form a weak imperfect and past participle, and which are these verbs?
3. Which word of a compound substantive takes the plural, and which remains unchanged?
4. In what circumstances do both words show the plural form?
5. How is the plural of compounds with -mann formed?
6. Which nouns denoting measure do not take the plural, and which form the plural with the usual inflections?
7. Which nouns of measure always take the inflectional -n in the plural?
8. How is the position of the verb influenced by a subordinative conjunction, introducing a subordinate clause?
9. How is the auxiliary verb in compound tenses placed in a subordinate clause introduced by the subordinative conjunction?
10. What rule has to be observed with regard to the position of subject and verb in clauses where the subordinative conjunction is placed at the beginning of the compound sentence?

Exercise 1. (*a*) Change the present tense of the verbs in the following sentences into the *imperfect* and *perfect:*

Ich bleibe zu Hauſe; du pfeifſt laut; das Mädchen
I stay at home; you whistle loudly; the girl
reibt die Diele; wir ſchreiben Briefe; das Kind
scrubs the floor: we write letters; the child
ſchreit entſetzlich; die Männer ſchweigen;
is screaming terribly; the men keep silence;
wir ſteigen auf den Berg; ich verzeihe Ihnen;
we ascend the mountain; I forgive you;
der Hirt treibt das Vieh auf die Weide;
the shepherd turns the cattle out to graze;
der Knabe weiſt mir den Weg ins Dorf.
the boy shows me the way to the village.

(*b*) Change the imperfect and perfect of the following sentences into the present tense:

Ich biß in den Apfel; weshalb biſt du nicht
I bit into the apple; why did you not
bei uns geblieben? Der Künſtler ergriff das Inſtrument;
stay with us? The artist seized the instrument;
wir haben große Schmerzen gelitten; der Kutſcher
we have suffered great pain(s); the coachman
pfiff eine Melodie; das Mädchen hat eine Roſe
whistled a tune; the girl has pulled a rose
vom Zweige geriſſen; die Sonne ſchien hell;
off the branch: the sun was shining brightly;
der Bettler ſchlich an der Mauer hin; was haben Sie
the beggar crept along the wall; what have you
mir geſchrieben? Der Mann und die Frau
written to me? The man and the woman
ſtritten heftig.
quarrelled violently.

Exercise 2. (*a*) Change the singular of the compound nouns and words agreeing with them in the following sentences into the plural. [The compounds are indicated by the sign .]

Wo iſt mein Tinten faß (*n.*)? Ich kann nicht
Where is my inkstand? I cannot
meinen Hand-ſchuh (*m.*) finden. Geben Sie mir mein
find my glove. Give me my
Taſchen tuch (*n.*). Die Meſſer klinge (*f.*) iſt gebrochen;
handkerchief. The blade of the knife is broken;
die Pfauen feder (*f.*) iſt ſchön; das Arm band (*n.*)
the peacock-feather is beautiful; the bracelet
war aus Gold; der Fuß boden (*n.*) war
was of gold; the floor was
mit Teppichen belegt; das Wein glas (*n.*) iſt leer;
covered with carpets; the wine-glass is empty;
der Gold ſchmied (*m.*) hat ſchöne Ringe.
the goldsmith has beautiful rings.
Aus welchem Stoffe iſt Ihre Hals binde (*f.*)?
Of what material is your necktie?
Geben Sie mir gefälligſt das Obſt meſſer (*n.*).
Pass the fruit-knife, if you please.

(*b*) Change the plural of the compounds and words in agreement with them into the singular:

Die Sing vögel (*m.*) ziehen im Herbſt nach dem
The singing-birds migrate in the autumn to the
Süden; die ſeidenen Regen ſchirme (*m.*) ſind nicht ſehr
south; the silken umbrellas are not very
haltbar; die Augen-lider (*n.*) ſind geſchwollen; ich kaufte
durable; the eyelids are swollen; I bought
einige Erd-beeren (*f.*). Wohin führen dieſe Wald
some strawberries. Whither lead these forest-
pfade (*m.*)? Ich beſitze zwei Winter-röcke (*m.*).
paths? I possess two [winter] overcoats.

(*c*) Form the plural of the compound nouns and words agreeing with them in the following sentences. [Remember the rules concerning the plural of nouns with the indefinite article.]

Der Hauptmann (*m.*) kommandirte die Truppen;
The captain commanded the troops;
ich ſandte den Dienſtmann nach Hauſe; ein Kaufmann
I sent the messenger home; a merchant
muß rechnen können; ein Staatsmann ſollte
must know how to calculate: a statesman ought
nicht irren; ein junger Ehemann
not to [err] make mistakes: a young husband
iſt gewöhnlich nachgiebig.
is generally indulgent.

(*d*) Form the plural of the following nouns of measure, changing the cardinal numeral one into ten:

Ein Pfund Kaffee, ein Bund Stroh,
One pound of coffee, one bundle of straw,
ein Faß Petroleum, ein Buch Papier,
one barrel of petroleum, one quire of paper,
ein Sack Reis, eine Flaſche Wein,
one bag of rice, one bottle of wine,
ein Ballen Wolle, eine Tonne Kohle,
one bale of wool, one ton of coal.
eine Woche, eine Stunde, eine Meile,
one week, one hour, one mile,
ein Kubik-Fuß Holz, eine Kiſte Zucker.
one cubic foot of timber, one case of sugar

Exercise 3. Reverse the following subordinate clauses by putting the second clause in the first place (for instance: Er ſah mich, ehe er fortging, he saw me before he went away; to be reversed: Ehe er fortging, ſah er mich, before he went away, he saw me):

Wir rauchten, nachdem die Damen ſich zurückgezogen hatten;
we smoked after the ladies had retired;
wir gingen fort, weil uns Niemand die Tür öffnete;
we went away because nobody opened the door for us;
er verſchwand, ehe ich ihm ein Wort ſagen konnte;
he disappeared before I could speak a word to him;
der Weizen wächſt, wenn es genügend viel regnet;
the wheat grows if it rains sufficiently;
er frug mich, ob ich zürne; er wünſchte
he asked whether I was angry; he wished
abzureiſen, falls das Wetter es zuließe;
to depart in case the weather would allow it;
ich ſchlief, als er kam; ſie ſang ein Lied,
I slept when he came; she sang a song
da man ſie bat, es zu tun; ich gehe nicht fort,
since she was requested to do so; I shall not go
ſolange Sie es mir nicht zugeſagt haben.
until you have promised it to me (literally: I go not away as long as you have not promised it me).

KEYS TO EXAMINATION PAPER XI.
(PAGES 2490–2491)

Exercise 1. *Imperfect:* Ich nahm das Geld; der Knabe ſtahl einen Apfel; was geſchah? ich las ein Buch; ihr ſaht nichts; gaben Sie nichts? du verbargſt etwas; wir warfen den Ball; die Dame ſprach engliſch; ich aß Erdbeeren.

Pluperfect: Ich hatte das Geld genommen; der Knabe hatte einen Apfel geſtohlen; was war geſchehen? ich hatte ein Buch geleſen; ihr hattet nichts geſehen; hatten Sie nichts gegeben? du hatteſt etwas verborgen; wir hatten den Ball geworfen; die Dame hatte engliſch geſprochen; ich hatte Erdbeeren gegeſſen.

Exercise 2. Das Luſtſpiel hat vier Akte; in ſeinen Träumen hatte er ſeltſame Geſichte; die Ritter erhoben ihre Schilde; der Richter brachte die Akten; alle hatten bleiche Geſichter; die Schilder über den Ladentüren waren gemalt; wie viele Bände haben Sie? Die Bänder des Hutes ſind rot; die Bauer der Vögel waren aus Gold; die Bauern kennen das Wetter.

Exercise 3. Wer iſt dieſer Herr? Was meinen Sie? Weſſen Hut iſt das? Wem gehört dieſes Buch? Wen ſahen Sie geſtern? Welchem Manne gehört das Boot? Welche Dame kennen Sie? Welche Kinder ſollen eingeladen werden? Was für ein glänzender Spieler er iſt! Welches ſchöne Kind ſahen Sie? Welch' ſchönes Kind! Was für Leute ſind ſie? Was für Getränke beſtellten Sie? Was für eine Frau war es?

Exercise 4. Diesſeits der Mauer, innerhalb des Gartens, ſtand ein Mann inmitten der Wieſe. Zufolge eines Berichtes (or: einem Berichte zufolge) war der Feind geflohen. Trotz meiner Warnungen ſprach er mit ihm; um des Himmels willen! Meinem Hauſe gegenüber wohnt ein Schneider ſeit einem Jahre; ich öffnete mittelſt eines Schlüſſels die Türe. Seit Ihrer Abreiſe ſah ich ihn nicht mehr; wir ſpazierten durch den Garten gegen den Wald; er tat es wider meinen Willen.
